Some of the Greek writers have called the *parthenium* by the name of the sweet marjoram, *amaracus*; and this has often occasioned great doubts, as to which of the two plants was meant. Dioscorides says, that the *parthenium* was by some called *Leucanthemum*; and by others, *amaracus*. Pliny says, that some called it *tamnacus*; but this is evidently only a false print, for he has trrnslated the before mentioned words of Dioscorides in the very order in which they stand in that author, and the word *tamnacus* should be *amaracus*. But this is not the only perplexity Pliny has occasioned about this plant: he has translated the account of it in a Greek author, which plainly shews, that the plant was the same that we now call by the name *parthenium*. Pliny has mistaken his original when he says, that it has a white flower, swelling like an apple; whereas the original says, that the exterior border of the flower was white, and the central part a discus yellow

The antients had another *parthenium*, which they distinguished by the name *murale*. This is our *parietaria*.

PARTISAN, in the military art, the commander of a *partisan* party.

PARTISAN-*party*, a small body of infantry given to a *partisan*, to make an incursion upon the enemy, to lurk about their camp, to disturb their foragers, and to intercept their convoys.

PARTITION (*Cycl.*)—PARTITION, in husbandry. The *partitions* in land sown with wheat by the drill, for the horse-hoing husbandry, are different according as the wheat is sown, in double, treble, or quadruple rows. The double row has but one *partition*, and this is best to be used in cases where the land is suspected to be full of the seed of weeds, which must be taken out with the hand hoe. This *partition* should be twelve or fourteen inches wide. Whole fields drilled in these rows may be hand-hoed at the expence of four shillings an acre; and when there is but one foot in six, the price of that work ought to be proportionable.

The common width of the two *partitions*, when the wheat is sown in treble rows, is six or eight inches. Care is to be taken in this particular; for, if they are planted closer, they will starve one another before the intervals are hoed to give them a fresh supply of nourishment; and if they are planted too far asunder, the two outer rows will thrive well, but the middle row will be starved, and look worse and weaker, because of its being at so great a distance from the hoed intervals. In quadruple rows the *partitions* are best to be seven inches wide each: at this distance the plants will thrive sufficiently, and if they are set nearer, the whole will be worse; and if farther off, the two outer rows will thrive, but the two inner ones will be starved, by reason of their distance from the plowed intervals.

PARTITION, *partitio*, in rhetoric, the same with division. See the article DIVISION.

PARTITIONE *facienda*, in law, a writ which lies for those who hold lands or tenements *pro indiviso*, and would sever to every one his part, against them that refuse to join in partition, as copartners, &c. F. N. B. 61, 31 H. 8. c. 1. *Cowel.*

PARTITURA, in the Italian music, the same as *partition*. See PARTITION, *Cycl.*

PARTNER (*Cycl.*)—PARTNERS, in a ship, are strong pieces of timber bolted to the beams incircling the masts, to keep them steady in their steps, and also keep them from rolling, that is, falling over the ship's sides. There are also of these *partners* at the second deck, to the same end; only the missen-mast hath but one pair of *partners*, in which that mast is wedged so firm that it cannot move. Some ships do not sail well unless their masts are loose, and have leave to play in the *partners*; but in a storm this is dangerous, lest the *partners* should be wronged, (as they say) *i. e.* forced out of their places; for then there is no help but to cut the mast by the board.

PARTRIDGE, *perdix*, in ornithology. See PERDIX.

The *partridge* is a timorous and simple bird, and is so valuable at the table, that there are a great many ways of taking it invented by sportsmen, all of which succeed from the folly and fear of the animal.

The places that *partridges* most delight in, are corn-fields, especially while the corn grows; for that is a safe retreat, where they remain undisturbed, and under which they usually breed. They frequent the same fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a sufficient shelter for them under the covert of the stalks, especially those of wheat stubble. When the wheat stubble is much trodden by men or beasts, they retire to the barley stubble, and will there hide themselves in coveys of twenty or thirty. When the winter comes on, and the stubble fields are trodden down or ploughed up, they then retire to the upland meadows, where they lodge in the high grass and among the rushes; sometimes they resort to the low coppice woods, especially if there be corn lands near them.

In the harvest time, when the corn fields are full of men, they are found in the fallow fields next to the corn fields, where they lie lurking among the weeds till evening, and then they get over into the corn, and feed late and early on the corn in the sheaves. When the proper haunts are known, the next thing is to find the birds in them: this is done variously, some will do it by the eye only; and this art can never be taught, but can be had only from long observation: the colour of the birds being so like that of the earth at a distance, that no eye but a very conversant one could distinguish them. When they are once seen, the business is to keep the eye upon them, and then to keep in continual motion. They are a very lazy bird, and by this means will let a person almost tread upon them; tho' if the person stands still to eye them, they will rise immediately, tho' they are at a considerable distance.

Another method of observing them is by going to their haunts very early in the morning, or at the close of the evening, which is called jucking time. The noise of the cock *partridge* is to be attended to at this time, and is very loud and earnest. The hen will soon come up to the cock after her making the noise, which she does by way of answer; and when they are got together, their chattering will discover them. Thus they may always be found at these times: but there is a yet better method of finding this bird, which is by the call. The business, in order to have success in this way, is carefully to learn the notes of the *partridge*, and be able to imitate all the several sounds. When perfect in this, the person is to go to the haunts morning and evening, and placing himself in some place where he can see the birds without being seen by them, he is to listen to their calling; and when they are heard, he is to answer in the same notes, doubling again as they do: by continuing this, they may be brought so near, that the person lying down on his back may count their whole number. Having in this manner found where the birds are, the next care is to catch them.

They are so foolish, that it is extremely easy to take them in nets. In order to this, there needs no more than the going out, provided with two or three nets, with meshes somewhat smaller than those of the pheasant nets, and walking round about the covey, a net is to be fixed so as to draw over them, on pulling a line at a distance. All this may be easily done; for so long as the sportsman continues moving about, and does not fix his eyes too intently upon them, they will let him come near enough to fix the nets, without moving. If they lie so straggling, that one net will not cover them, then two or three must be fixed in the same manner. The sportsman may then draw the nets over them, and they will often lie still with the nets upon them till he comes up to fright them, then they will rise and be entangled in the net.

A second method of taking them is with bird-lime: this is done by means of wheat straws. These must be large, and cut off between knot and knot; they must be well limed with the best and strongest bird-lime, and the sportsman must carry a great number of them out with him. Having found a field where there are *partridges*, he is to call; and if they answer, he is then to stick up the limed straws in rows across two or three lands, and going backward, call again to them, leading them on in the road where the straws are: they will follow one another like a flock of chickens, and come out to the call; and will in their way run upon the straws, and liming themselves, they will daub one another by crowding together, so that very few of them will be able to escape.

But there is yet a pleasanter way of taking them than this, that is, by driving of them: in order to this, an engine is to be made of canvas stuffed with straw, to represent a horse; this horse and nets are to be taken to the haunts of the *partridges*, and the nets being placed slanting or slopewise in the lower part of the field, the sportsman is to take the wind in his back and get above them, driving them downwards; his face is to be covered with something green or blue, and placing the horse before him, he is to go towards them slowly and gently; and by this means they will be raised on their legs, but not on their wings, and will run before the horse into the nets. If in the way they go into a wrong path, the horse is to be moved to face them; and they will be thus turned back again, and driven every way the sportsman pleases.

Indian PARTRIDGE, *coturnix Indica*, the name given by the Spaniards to a bird of the West Indies, of which there are three or four species; all which, Nieremberg says, are properly of the *partridge* kind. See the articles COLIN, and QUAUHTZONECOLIM.

Red-legged PARTRIDGE, a very delicate and valuable bird, called *cutumo* by the Italians.

It is distinguished from the common *partridge* by the redness of its beak and legs. It is of a greyish ash colour on the back; its throat is white near the head, but has a small black spot on each side at the angle of the bill, and this white space is surrounded by a black line; its breast is of a yellowish brown, and its wings are variegated with black, yellowish, and white. It is not found in England, but is sometimes shot in the islands of Guernsey and Jersey. *Ray*'s ornithology, p. 122

PARTY (*Cycl.*)—PARTY-*bleu*, in the military art, a name given to a party of robbers who infested the roads in the Netherlands. They belonged to neither army, but robbed both sides, without any regard to passes.

PARTY-*china*, a name given by the English merchants and others to a sort of porcelain or china-ware, which is elegantly painted on the outside with some bright colour, and blotted or variegated with round or square spots of a different tinge. The manner in which the Chinese do this is a very simple and easy one, and may be imitated in our own potteries with great ease. They prepare as many pieces of paper as they intend to have spots on the vessel, and cut them exactly into the shape of those spots: they wet these, and then spread them smoothly on the places where the spots are to be. When this is done, they cover the vessel with the brown and gold, or any other varnish, and then take off the papers: in the places which they covered no varnish has come, so that they are so many regular white spaces. These they cover with some other colour, laying it on carefully with a pencil: when this is done, they varnish over the whole vessel with the common varnish, and bake it. In some vessels they lay on only plain blue, or plain black in the spaces destined for spots; and after the first baking they cover these with gold, and make them so many figures of squares, triangles, or globes in pure gold. Observ. sur les Coutumes de l'Asie.

PARU, in natural history, the name of a very singular American fish.

It is broad, flat, and roundifh; of no great thicknefs, and is ufually of about five or fix inches long, and more than four broad. It has fix fins, one large and long, one on the back, and another on the belly, behind the anus. Each of thefe reaches to the tail, and has, toward the end, a long ftring or cord, made of a fingle filament; that, on the back fin, be ing longer than that on the belly. Behind the gills it has alfo two fins of two fingers breadth long, and one broad; and two others on the belly, which are very narrow. Its head is fmall, and its mouth elevated and fmall, and furnifhed with fmall teeth. Its fcales are of a moderate fize, and are half black and half yellow; fo that the fifh appears of a black colour, variegated with yellow half moons. Its gills, and the beginning of its fins, are alfo yellow; and it has, on each fide near the head, a yellow fpot; it is an eatable fifh. *Marggrave*'s Hift. of Brafil.

PARULIDES, in furgery. See Gum-*boils*.

PARUS, the *titmoufe*, in zoology, the name of a genus of fmall birds, of which there are feveral fpecies; fome very common with us, the others of foreign origin. The Englifh kinds are, 1. The *fringillago*, or great *titmoufe*. See Fringillago. 2. The *parus ater*, or *colemoufe*, which has a black head, white fpot on the back part of it, a greyifh green back, and a green rump. This is the fmalleft of all the kind, not weighing above two drams. 3. The *parus paluftris*, or *marfh titmoufe*, commonly called the *black cap*. This is fomething larger than the colemoufe, and weighs three drams; its head is black, but its jaws white; its back greenifh, and its feet of a lead colour. It has a larger tail alfo than the colemoufe, and wants the white fpot at the back of its head, which is its diftinguifhing character. 4. The *parus cæruleus*, or *blue titmoufe*, or *nun*. This is of the fame fize with the black cap, but its head is blue, with a circle of white drawn round it; and round that white circle there is another of different colours, which furrounds the back part of the head and throat; there runs on each fide a black line, from the beak to the hinder part of the head, and the jaws are white; the back is of a greenifh yellow, its fides, breaft, and belly, yellow; but there runs a white line longitudinally down the middle of its breaft 5. The *parus caudatus*, or *long-tailed titmoufe*. The head of this fpecies is white, the neck black, and feveral black lines of the fame colour, run from the beak to the back of the head; the breaft is white, variegated with fmall fpots of brown; the belly and fides are of a pale chefnut colour. Its tail is extremely long, and is variegated with black and white. It is found in gardens and orchards, and builds its neft with great art and nicety. *Marggrave*'s Hift. of Brafil.

The kinds not known to be found in England, are the blue American one called *guiracenoia*. See Guiracenoia. The *paruscriftatus*, or *crefted titmoufe*, known by its black head being fimbriated with white feathers, and its creft, which it can at pleafure raife to a fingers breadth high: and the *parus fylvaticus*, or *wood titmoufe*, of Gefner and Aldrovand, which is very fmall, and is diftinguifhed from all others by a red fpot on its head. *Aldrovand*. de Avib.

The *titmoufe*, in the Linnæan fyftem of zoology, makes a diftinct genus of birds, of the order of the pafferes; the diftinguifhing characters of which are thefe: The extremity of the tongue is truncated, or as it were cut off, and terminated by four briftles, and the beak is pointed. *Linnæi* Syftema Naturæ, p 49.

The general characters of the *parus* kind, according to Mr. Ray, are, that they are all very fmall, and are fond of climbing about trees, where they feed on the fmall infects they find in their bark; tho' fome of them will alfo eat feeds. They are always reftlefs; their beaks are fhort, and their tails long; they make a confiderably loud noife, fome of them finging very agreeably; and all lay a great number of eggs. *Ray*'s Ornithology, p. 174.

PARVUS *nafi mufculus*, in anatomy, a name given by Cafferius, and fome others, to a fmall mufcle of the nofe, called by Albinus *compreffor naris*; by Winflow, *tranfverfalis*, or *inferior nafi*; and by Cowper, *elevator alæ nafi*.

Parvus *et tenuis palpebræ*, in anatomy, a name given by Fallopius to one of the mufcles of the face, called by Cowper and Douglafs, *aperiens palpebram rectus*; and by Albinus, the *levator palpebræ fuperioris*. See Aperiens, *Cycl.* and *Suppl.*

PARYPATE, in the antient mufic, was the name of that note or chord of a tetrachord which lay next to the hypate. As the hypate was the *principalis*, the firft or principal found, according to Martianus Capello's tranflation; fo the *parypate* was, according to him, the *fub principalis*. See the article Tetrachord.

The name *parypate* was given to this fecond note when a tetrachord was confidered feparately from others; but when combined, this chord fometimes took the name *trite*. See the articles Diagram and Trite.

Parypate *hypaton*, in the antient Greek fcale of mufic, was the fecond note of the hypaton tetrachord, and anfwers to C-fa-ut of Guido's fcale. *Wallis*, Append. ad Ptolem. Harm. p. 157. See Diagram and Parypate.

Parypate *mefon*, in the Greek mufic, was the fecond note of the *mefon* tetrachord, and anfwers to F-fa-ut of the Guidonian fcale *Wallis*, Append. Ptolem. Harm. p. 157. See Diagram.

PAS *de fouris*, in the military art, the fame with *liziere*. See the article Liziere, *Cycl.*

PASHA, an office of dignity under the Grand Seignior, otherwife called *bafhaw*. See Bashaw, *Cycl.*

All Egypt is, on the part of the Grand Seignior, governed by a *pafha*, who has in reality but little power; but feems principally to be meant for the means of communicating to his divan of beys, and to the divans of the feveral military ogiacs, that is, their bodies, the orders of the Grand Seignior, and to fee that they be executed by the proper officers.

If he farms the country of the Grand Seignior, the fines that are paid when any life drops upon the lands belong to him; for originally all the lands of Egypt belonged to the Grand Seignior; and the porte ftill looks on them as its own: but the Grand Seignior's power being now loft, they all go to the next heir; who muft, however, be invefted by the *pafha*, and is glad to compound for a fmall fum.

The nature of the *pafha*'s office requires him to be ever attempting means to cut off fuch as are too afpiring, or engaged in defigns that may be any way prejudicial to the porte. This often occafions his own depofition; but he is in no care about that, as his perfon is always facred; and his lofing this poft is only a ftep to higher preferment. *Pocock*'s Egypt, Vol. 1. p. 162.

PASHAUNA *beady*, in natural hiftory, a name given by the people of the Eaft Indies to a kind of fibrofe talc, found in the fides of the mountains, and ufed in medicine with them. They calcine it, and then powder and boil it in milk, and give half a dram for a dofe mixed in milk, for the gravel and ftone.

PASS (*Cycl.*)—Pass, among miners, a frame of boards confifting of two or three bottom boards and two fide ones, fet flope-wife; thro' which the ore flides down into the coffer of the ftamping mill.

PASQUE-*flower*, in botany. See Pulsatilla.

PASSACAGLIO, in the Italian mufic, is properly no more than a chacone. See Chacone.

The only difference then, is, that the movement of the *paffacaglio* is fomewhat graver, the tune fofter, and the expreffion lefs lively: they are for the moft part in the minor modes, or flat keys.

PASSADE, (*Cycl.*) in the manege. This cannot be performed without changing the hand, or turning and making a demitour at each of the extremities of the ground. Hence it is, that there are feveral forts of *paffades*, according to the different ways of turning, in order to part or put again, and return upon the fame pifte, or tread; which we call clofing the *paffade*. See Close and Serrer.

A paffade of five times, or a demivolt of five times, is a demitour made at the end of the ftraight line, one hip in, in five times of a gallop upon the haunches; and at the fifth time ought to have clofed the demivolt, and to prefent upon the *paffade*-line ftraight and ready to return. The demivolts of five times or periods, are the moft common airs of changing the hand or turning, that are now practifed.

Furious paffades, thofe performed upon a full career, being moftly ufed in duels. To make thefe *paffades*, you put your horfe ftraight forwards, and towards the extremity of the line make a half ftop, keeping the horfe ftraight without traverfing; then you make the demivolt at three times, in fuch a manner, that the third time the horfe prefents ftraight upon the *paffade*-line ready to fet out again upon a fhort gallop. You continue this fhort gallop half the length of the *paffade*, then you put on furioufly at full fpeed; and at the end of the *paffade* mark a half ftop, and then a demivolt of three times. This you continue to do as long as the horfe's wind and ftrength will hold. This *paffade* at full fpeed, fuppofes that the horfe has an excellent mouth, and requires ftrength and agility both in the horfe and horfeman. There are but few horfes that are capable of it.

Paffade of one time, is a demivolt or turn, made by the horfe, in one time, of his fhoulders and haunches. To make this *paffade*, which is the moft perfect of all, the horfe fhould ftand ftraight upon the *paffade*-line; and then putting forwards, he forms a half ftop, making falcades two or three times in fuch a manner, that he is ftill ftraight upon the line; and at the laft time he prepares to turn nimbly, and retain to fix his haunches as a center; fo that the demivolt is performed in only one time of the fhoulders: and tho' the haunches make likewife a time, they make it in the center, or upon the fame fpot, and *de ferme a ferme*, as the French call it.

Raifed or high paffades, are thofe in which the demivolts are made in corvets.

In all *paffades* the horfe fhould, in making the demivolt, gather and bring in his body, making his haunches accompany his fhoulders, without falling back, or not going forward enough each time: and he fhould go in a ftraight line, without traverfing or turning his croupe out of the line.

PASSAGE (*Cycl.*)—*Birds of* Passage, a name given to thofe birds which at certain ftated feafons of the year remove from certain countries, and at other ftated times return to them again, as our fwallows, and many other fpecies.

The places to which thefe birds retire on their leaving the countries in which they have made their abode, for a certain

feafon,

seafon, not having been ever perfectly known, fome have formed idle conjectures of their not going away, but remaining torpid in hollow trees, in caverns, and under waters; but thefe are too abfurd to gain credit with the thinking part of the world; and their whole journey feems directed by inftinct toward fuch parts of the world as will afford them food, when that whence they depart will no longer do fo: this want of food feems in all the fpecies to be the chief reafon of their departure; and the plenty of it in an after-feafon, that of their return from a place which then, perhaps, affords it no more.

The generality of birds that remain the winter with us, have ftrong bills, or are enabled to feed on what they can find at that feafon; thofe which leave us, have ufually very flender bills, and their food is the infects of the fly kind; which difappearing toward the approach of winter, compel them to feek them in regions where they may be found; and the length of the wings of the generality of thefe birds, enables them to prey flying, if there be food for them in their way, and to continue a long time on the wing without reft.

The various conjectures about the places to which they retire, are owing to want of ocular teftimony; but if we confider the vaft tracts of land yet unknown to us, we cannot doubt but there may be many places for them, in which we can have had no opportunities of finding them. But the moft probable conjecture feems, that the places to which they retire lie probably in the fame latitude in the fouthern hemifphere, as the places from whence they depart; where the feafons reverting, they may enjoy the like agreeable temperature of the air. And if thefe places are fuppofed to be divided from them by too large feas, why may not fome other parts of the fouthern hemifphere, which are lefs diftant, ferve their turn?

This, certainly, feems much more reafonable than that they fhould remain on our fide of the northern tropic, within a few degrees of which, at the winter folftice, it is fo cold as frequently to produce fnow; which, by difperfing fuch infects as birds that feed upon the wing fubfift on, muft make them perifh, were they not to remove to thofe warmer climates where they may ftill find food.

The fwallows, as they cannot fubfift fo long in cold feafons as fome other birds of *paffage*, which feed after the difappearance of flies in the air, on what infects they find in their receffes, vifit us later, and depart from us fooner, than the reft. The nightingales, and fome other birds, which leave us for the winter, are feen, fometimes, a month after the fwallows: and from the whole it feems natural to infer, that the fwallows pafs the tropic of Cancer, tho' it is not yet known to what place they at length retire.

The manner of the birds of *paffage*, journeying to their fouthern abode, may vary, according to the different ftructure of their bodies, and their power of fupporting themfelves in the air. Thofe birds with fhort wings, fuch as the redftart, blackcap, *&c.* tho' they are incapable of fuch long flights as the fwallow, or of flying with fo much celerity, yet may pafs to lefs diftant places, and by flower movements. Swallows and cuckows, may perform their paffage in a very fhort time; but there is for them no neceffity for fpeed, fince every day's paffage affords them an increafe of warmth, and a continuance of food.

Providence, which has guided the defencelefs animals in many other inftances to the fafeft methods of performing their neceffary works, may have inftructed many of thefe birds which have fhorter paffages to make, or places to ftop at by the way, to fly only in the night, that they may be fecure from the birds of prey: and Mr. Catefby gives a proof that fome fpecies do fo, from his own obfervation; for lying on the deck of a floop on the north fide of Cuba, himfelf and the whole company, heard fucceffively, for three nights, flights of rice birds, which are eafily diftinguifhed from all others birds by their notes, and which were paffing over their heads northerly; which is their direct way from Cuba, and the fouthern continent of America, from whence they got to Carolina, annually about the time that rice begins to ripen, and from whence they return fouthward again, when it is gathered, and they are become fat.

The fhort winged birds are fuppofed little qualified for long flights, particularly the quail, which is a bird never feen long together on the wing, or making any long flights: its not doing this frequently, is, however, no proof that it is not able to do it; nor does the ftructure of its body at all befpeak its inability: and Bellonius affirms, that he faw them in great flights paffing over, and repaffing, the Mediterranean fea, at the very feafons when they leave us, and return to us again. The fame inftinct that directs thefe birds to depart to diftant countries, doubtlefs, alfo directs them to the fhorteft way, and fends them to the narroweft cuts, not the wider feas to crofs.

Among the birds of *paffage*, we have fome alfo which come to us in the autumn, at the time when the fummer birds are leaving us; and go from us again in the fpring at the times when thefe return: thefe, however, are only four kinds; the fieldfare, the redwing, the woodcock, and the fnipe; and of thefe, the two laft often continue with us thro' the fummer, and breed; fo that the two firft feem the only kinds that certainly leave us at the approach of fpring, retiring to more northern parts of the continent, where they live the fummer and breed; and at the return of winter, are driven foutherly from thofe frigid climes, in fearch of food, which there the ice and fnow muft deprive them of. There are many others alfo, particularly of the duck or wading kind, that breed and make their fummer abode in the defolate fenny parts of our ifland; and when the feverity of our winters deprives them of their food, neceffity forces them to retire toward the fea in numerous flights; where they find water unfrozen, and where they remain till the return of fummer; but thefe cannot properly be called birds of *paffage*.

It feems pretty evident from the whole, that the fummer birds of *paffage* leave us only in fearch of a more warm climate, and a greater plenty of food; both which advantages they procure to themfelves by their alternate change of climate; but the migration of the winter birds of *paffage* is not fo eafily accounted for, fince there is no fuch apparent neceffity of their leaving us either on the fcore of food, or climate.

The place of the fummer retirement of thefe birds is Sweden, and fome other countries in that latitude; but as they would find thofe places too cold and deftitute of provifion, were they to haften immediately to them on their departure from us, they journey along gradually, and prolong their paffage thro' the more moderate countries of Germany and Poland; by which means they do not arrive at their northern habitations, where they are to pafs their fummer, and where they breed till the feverity of the cold is fo far abated as to render it pleafing to them, and there is proper food there for them: and when they revifit us the following winter, thier journey is performed in the fame leifurely manner.

Sweden, and the other countries whence they come to us, feem the proper home of thefe birds; fince there they were bred; and the journey they take to us being only for a warmer climate, and a plenty of food, it is no wonder that when thefe benefits are to be expected again in their native place, they return to it.

The principal food of thefe birds, while with us, is the fruit of the white thorn, or haws; which hang on our hedges, in winter, in prodigious plenty; but where they breed, and feem to live moft at eafe, as in Sweden, *&c.* there are no haws, nor indeed in many of the countries thro' which they journey in their way; fo that it is evident they change their food in their paffage. And upon the whole it appears, that Providence has created birds, *&c.* with conftitutions and inclinations adapted to their different degrees of heat and cold; which, to them, are moft agreeable, and to which they will travel from places which to other animals might feem more agreeable: by this means no part of the globe is without its inhabitants.

Befide the migratory birds, which live in different countries a whole winter, or a whole fummer, there are fome others which annually appear in particular places, at the time of the ripening of particular kinds of grain which their own country is deftitute of; and thefe depart after a fhort ftay, and are no more feen till that time the following year. Of this kind are the rice-bird, and bluewing of Carolina. Birds like men, purfue their fearches after food, or whatever elfe is neceffary and agreeable, thro' diftant climes; and when they difcover fome new grain, or pleafing food, they return and acquaint their community of the good fortune, and then joining in numerous flights, make annual excurfions to folace themfelves on this exotic food.

Since the difcovery of America, there have been introduced from Europe feveral forts of grain which were before unknown there, and which, not before fome length of time, were found out, and coveted by birds of this migratory kind. Of this fort there is a very beautiful fpecies, which has very lately made its firft appearance in Virginia: thefe arrive annually at the time that the wheat is ripe, or nearly fo; and conftantly fince they found it out, have appeared in great droves every year, at the feafon of its ripening; the inhabitants call them, for this reafon, *wheat-birds.* Phil. Tranf. Nº 483.

PASSAGE, in the manege. To *paffage* a horfe upon his own length. See LENGTH.

PASSAGIO, in the Italian mufic. See PASSAGE, *Cycl.*

PASSAGO, in the glafs trade, the inftrument with which the workman makes the bowl of the drinking glaffes, or other the like veffels. *Neri*'s Art of Glafs, p 247.

PASSARADO, in a fhip, is a rope whereby all the fheet-blocks of the main and fore fails are haled down; the clew of the main fail to the cubbridge-head of the main maft, and the clew of the fore fail to the cat-head. This is to be done when the fhip goes large; and they are alfo kept firm down, and hindered from flying up, by this *paffarado* rope.

PASSEPIED, in the French mufic, an air in all refpects like a minuet, except that it is more brifk and lively. See the article MINUET.

PASSER, the *fparrow*, in zoology, the name of a large genus of birds, the diftinguifhing characters of which are thefe: they feed on corn and worms; their beak is thick, fhort, and fomewhat bent; their colour commonly a dufky brown.

There

There are many known species of this bird. 1. The common house *sparrow* 2. The *passer stultus*, or foolish *sparrow*, which is of a yellowish brown, with dusky streaks. 3. The bastard *sparrow*, *passer congener*, of Aldrovand, which is of a reddish brown, and has no black spot under its throat. 4. The *passer tricolor*, or three coloured *sparrow*; this is variegated with an equal proportion of black, white, and yellow. 5. The *passer albicilla*, or white-tailed *sparrow*, distinguished by its greyish white tail. 6. The *passer Illyricus*, or Illyrian *sparrow*, which is larger than the common kind, and has a very white belly. 7. The *passer torquatus*, or ring *sparrow*, which is very small, and has a white ring about its eyes: the spot under the throat, which is black in the common *sparrow*, is yellow in this species. 8. The *passer Indicus caudatus porphyromelas*, or long tailed black and red Indian *sparrow*. 9. The *passer Indicus*, called *tijepiranga*. See TIJEPIRANGA. 10. The *passer Indicus macrouros rostro miniaceo*, or long-tailed Indian *sparrow*, with a red beak. 11. The *passer Indicus macrouros alius* of Aldrovand, or the other long-tailed Indian *sparrow*; a very beautiful bird, with a blue beak and a black head; the body being mostly of a fine scarlet. 12. The *passer Indicus brachyuros*, or short-tailed Indian *sparrow*, which is small, and all over of a bluish black. 13. The *passerculus brachyuros Europæanus*, or European small short-tailed *sparrow*: this is common in Italy, and is very small, and all over of a pale yellow. 14. *Passer erythromelas Indicus, sine uropygio*, the red and black Indian *sparrow*, with no tail. 15. *Passer Indicus cyanerythromelas, sine uropygio*; the blue, black and red Indian *sparrow*, without a tail. These are described by Marggrave; but he only saw the figures of them, so that the painter, not nature, perhaps, denied them tails. 16. The *passer montanus*, or mountain *sparrow*: this is common in Carinthia, and is variegated with a brownish red and black. 17. The *passer sylvestris*, or field *sparrow* of Aldrovand: this is of the size of the common *sparrow*, and is of a dusky rust-coloured brown, and has a broad streak running from the angle of its beak to its tail. And lastly, 18. The Brasilian *sparrow*, called *Guiranheemgatu*. See GUIRANHEEMGATU. *Ray*'s Ornithology, p. 184. *Aldrovand* de Avibus, l. 15 c. 33. *Ray*'s Ornithology, p. 182, to 186. *Aldrovand* Hist. l. 15. c. 16.

In the Linnæan system of zoology, the *passer* is one of the orders of the bird kind; the distinguishing mark of which is, that the beak is of a conic form, and tapers to a point. *Linnæi* System. Natur. p. 48. See Tab. of Birds, N°. 29 and 38.

PASSER, in the history of fishes, the name of the common plaise, a flat fish, of a dusky olive-colour, spotted with red on the back, and white on the belly, called in Latin also, *quadratulus* and *platessa*. *Willughby*'s Hist. Pisc. p. 96.

PASSER-*aquaticus*, the water *sparrow*, the name of a bird described by Nieremberg, which he says the Indians call *acototlequichitl*. It sings all day long without ceasing, but with no very pleasing note: it is, however, a well tasted bird; it lives among sedge and bushes, and is of the size and shape of a swallow, but has a black bill and yellow legs; its breast and belly are white, and its back is of a brownish yellow, variegated with spots of black and white. This bird much resembles our reed *sparrow*. *Ray*'s Ornithol. p. 300.

PASSER-*arundinaceus*, the reed *sparrow*, a bird of which there are two species, a greater and a smaller, both living among reeds and in watery places, and both singing very sweetly: the greater is known among authors by the name of *junco*, and the lesser by that of *cannevarola*. *Ray*'s Ornithology, p. 99. See JUNCO and CANNEVAROLA.

PASSER *arundinaceus torquatus*, the ringed reed *sparrow*, the name of a small bird, scarce exceeding the linnet in size, found among reeds, and always building its nest among them. Its head is black; its neck has a very beautiful ring of white, reaching to the angle of the beak on each side; its throat is black, and its breast and belly white; its back and wings are of a brownish black, and its rump bluish or greyish, with an admixture of brown. In the female the ring scarce appears, and the colours on the throat are reddish, brown, black, and grey. *Ray*'s Ornithol. p 197.

PASSER *asper*, in ichthyology, the rough or scaly *plaise*, called in English the *dab*; a flat fish, something thicker than the common *plaise*, and of the same general size, covered with considerably large scales, rough at their extremities, and edged as it were with teeth: the eyes are on the left side, and are placed very close together: its back is of a reddish grey, spotted with yellow, and the mouth moderately large. It is caught in the Mediterranean and English seas. *Rondelet*. de Pisc. p. 352.

PASSER *Britannicus*, in ichthyology, a name given by Charleton to the soal fish, and by some others to the turbut. See the articles HIPPOGLOSSUS, and PLEURONECTES.

PASSER *canarius*, and *canariensis*, in zoology, the common name for what we call simply in English, the *canary bird*.

The *canary bird* may be bred with us, and if treated with proper care, they will become as vigorous and healthful as in the country from whence they have their name. The cages in which these birds are kept are to be made of either walnut-tree or oak, with bars of wire, because these being woods of strength, do not require to be used in large pieces; and the more freedom they have of looking about them, the less will they be startled at people going up to them. The common shape of cages, which is cylindric, is very improper for these birds; for this allows little room to walk, and without that the birds usually become melancholy. The most proper of all shapes is the high and long, but narrow.

If these birds eat too much they grow over fat, lose their shape, and their singing is spoiled; or at least they become so idle, that they will scarce ever sing In this case their victuals is to be given them in a much smaller quantity, and they will by this means be recovered, by degrees, to all their beauty, and will sing as at first.

At the time that they are about to build their nests, there must be put into their cages some hay, dried thoroughly in the sun: with this must be mixed some moss dried in the same manner, and some stag's hair; and great care is to be taken of breeding the young, in the article of food. As soon as the young birds are eight days, or somewhat more old, and are able to eat and pick up food of themselves, they are to be taken out of the cage in which they were hatched, and each put separately into another cage, and hung up in a room where it may never have an opportunity of hearing the voice of any other bird. After they have been kept thus about eight days, they are to be excited to sing by a bird pipe; but this is not to be blowed too much, or in too shrill a manner, lest they sing themselves to death.

For the first fifteen days the cages are to be covered with a black cloth, and for the fifteen days following with a green one. Five lessons in a day from the pipe are sufficient for these young creatures, and they must not be disturbed with several sounds at the same time, lest they confound and puzzle them: two lessons should be given them early in the morning, one about the middle of the day, and two more at night. *Hervieux*, des Serins de Canarie.

The genius and temper of the several birds of this kind are very different. The males are almost always melancholy, and will not sing unless they are excited to it by hearing others continually singing about them. The male bird of this kind will often murder the female put to him for breeding; and when there are several females together with the males, they will often do the same to one another with jealousy. It is therefore not easy to manage the article of their breeding well in this particular, unless in this manner: let two female birds be put into one cage, and when they have lived together some time, they will have contracted a sort of love for one another, which will not easily be dissolved. Put a male bird into the cage with these two, and every thing will go well; their friendship will keep them from quarrelling about his favours, and from danger of his mischievous disposition; for if he attacks one of them, in order to kill her, the other will immediately take her part, and after a few of these battles, the male will find that they are together an overmatch for him at fighting, and will then distribute his favours to them, and there will not fail of being a young breed or two, which are to be taken away from their parents, and educated as before directed.

Some males watch the time of the female's laying, and devour the eggs as fast as she deposits them; and others take the young ones in their beaks, as soon as hatched, and crush them to death against the sides of the cage, or some other way destroy them. When a male has been known once to have been guilty of this, he is to be shut up in a small cage, in the middle of the large one in which the female is breeding her young, and thus he will often comfort her with singing all day long, while she sits upon the eggs or takes care of the young ones; and when the time of taking away, to put them into separate cages, is come, the male is to be let out, and he will always after this live in friendship with the female.

If the male become sick during the time of the female's sitting or bringing up her young, he must be removed immediately, and only brought to the side of her cage at certain times, that she may see him, till he is perfectly cured; and then he is to be shut up again in his cage in the middle.

PASSER *faber*, in zoology, a name given by Nieremberg to a bird, the genus of which we are not very certain about; it being also called *turdus chiappæ*. It is remarkable for perforating the bark of the pines, and lodging its acorns there, which it afterwards eats occasionally. *Ray*'s Ornithol. p. 303.

PASSER *fluviatilis*, in ichthyology, the name of the common flounder, distinguished from other fish of that genus by the smallness and close situation of its scales, which are such, that which ever way it is rubbed, the hand perceives no roughness; and that at the insertion of the fins there is a series of short prickles bent backwards, which are easily perceived by the touch, or by the eye on a close view. *Willughby*'s Hist. Pisc. p. 98.

PASSER *mosquitus*, a name by which some have called the *guainumbi*, or *humming bird*, the smallest of all birds. Ornithol. See GUAINUMBI.

PASSER *niger*, in ichthyology, a name given by Artedi from Charleton, to the common flounder The *flesus* and *fletelatus* of authors, and the *plaad* of the Germans.

PASSER *solitarius*, the solitary *sparrow*, a name given by authors to a bird properly of the *merula* or *black-bird* kind, and of the same size and shape with the common black bird, and not very different from it in colour.

Its head and neck are large and thick; the upper part of its head of a dusky grey, and its back of a deep bluish black, but with a little whiteness at the ends of the feathers; its tail is of a brownish black, and its wings are variegated with brown, black, and a little white; its breast, throat, and belly are beautifully variegated with black, white, and grey; its beak is long and strong, and its legs of a blackish brown, and very short: it feeds on berries and other vegetables. The male is more beautiful than the female, and has a cast of purple in the blue of his back. It sings very sweetly, and loves the tops of old buildings. It builds in the same places, and is the bird mentioned in the book of psalms. It is much esteemed for its singing, and will learn to imitate the human voice, and talk as the starling, parrot, *&c.* *Ray's* Ornithol. p. 140.

PASSER *stultus*, in ichthyology, a name given by Nieremberg to a species of the *larus*, or, *seagull*, so tame and foolish that it will stand still for any to lay his hand upon it. *Nieremberg.*

PASSER *troglodites*, in zoology, the name by which authors call the small bird known in English by the name of the *wren*. Some have very erroneously called this the *regulus*, which is the name of a perfectly different bird. See REGULUS.

Our *wren*, tho' a very small bird, is three times as large as the regulus, and of a brownish colour, with transverse streaks of black on its back, wings, and tail; a yellowish throat and a white breast, with some transverse streaks of black also on its lower part, and its belly of a reddish hue; and singing very sweetly and melodiously, much finer and louder in its voice than could be expected from so small a bird. *Ray's* Ornithol. p. 164.

PASSERINE, in botany, a name by which Ruellius and some other authors have called the common *alsine* or *chickweed*.

PASSION *(Cycl.)*—PASSION-*flower*, *granadilla*, in botany. See the article GRANADILLA.

The different species of this plant cultivated in the gardens of the curious are very numerous, and most of them very beautiful.

The three more common kinds, which are what we see in most gardens, are very hardy, and bear all the severities of our climates as well as if natives of it; for, tho' the tender branches, and sometimes even the main stem, are destroyed in our severer winters, yet it always shoots up again from the root.

These are propagated by laying down their branches, which in one year's time will take good roots, and may be removed to the places where they are designed to remain. The best season for transplanting them is the latter end of March or the beginning of April: they should be planted against a wall, or other building, which faces the south east or south west; or else mixed among the flowering shrubs in quarters of large gardens: in this case they must be trained up to poles fixed in the earth for that purpose, and thus will flower well, and appear extremely beautiful. The best season for pruning them is in the spring, and it is a good custom to lay a foot thickness of mulch at the roots, which will effectually preserve them from the severity of the winter, and is necessary when they are planted in open quarters, and have not the defence of a wall behind them. The manner of pruning is to cut entirely off all the weak shoots, and shorten the strong ones to about three feet in length. When they are planted against high buildings, they may be left something longer than this, to fill up the wall; but this is not very necessary, for they are very quick growing plants, and in open quarters they should be always pruned much shorter than this, to bring their flowers nearer the ground.

The most common kind with us never bearing fruit in this climate, can never be propagated any way but this; but there is another species which has by some been mistaken for the same, tho' really very different, which constantly bears fruit with us; and the plants of this may be raised from seeds in the common way. *Miller's* Gard. Dict.

Hysteric PASSION. See HYSTERICS.

PASSIONATO, in the Italian music, intimates that the part to which it is annexed ought to be played passionately, or in a moving and affecting manner.

PASSULATUM, a name given by the antients to medicine composed of the pulp of raisins passed through a sieve, sometimes alone, sometimes with other ingredients.

PASSUM, a name given by the antients to a kind of wine made of grapes, which had been suffered to remain on the vines till much withered and dried up: it is hence used also by some of the moderns to express raisin wine.

PASTE *(Cycl.)*—PASTES, in the glass trade, a sort of compositions of the glass kind, made from calcined crystal, lead, and metallic preparations, to imitate the several natural gems These are no way inferior to the native stones, when carefully made and well polished, in brightness or transparence, but want their hardness.

The general rules to be observed in the making them are these: 1. That all the vessels in which they are made are firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels are chosen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry stone, not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantities of the several ingredients be nicely observed. 5. That the materials be all well mixed; and if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot; for if this be not observed, they will be full of blisters and air-bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients. *Neri's* Art of Glass, p. 127.

To make a *paste* of extreme hardness, and capable of all the colours of the gems, with great lustre and beauty, take of prepared crystal ten pounds; salt of polverine, six pounds; sulphur of lead, two pounds; mix all these well together into a fine powder, make the whole, with common water, into a hard *paste*, and make of this *paste* small cakes, of about three ounces weight each, with a hole in them made in their middle; dry these in the sun, and afterwards calcine them in the straightest part of a potter's furnace; after this powder them, and levigate them to a perfect fineness on a porphyry, and set this powder in pots in a glass-furnace to purify for three days; then cast the whole into water, and afterwards return it into the furnace, where let it stand fifteen days; in which time all foulness and blisters will disappear, and the *paste* will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined: for a sea-green, brass simply calcined to a redness: for a sapphire, add zaffer, with manganese: and for a topaz, manganese and tartar. All the gems are thus imitated in this, by the same way of working as the making the coloured glasses; and this is so hard, that they very much approach to the natural gems. *Neri's* Art of Glass, p. 142.

The colours in all the counterfeit gems made of the several *pastes*, may be made deeper or lighter, according to the works for which the stones are designed; and it is a necessary general rule, that small stones for rings, *&c.* require a deeper colour, and large ones a paler. Besides the colours made from manganese, verdigrease, and zaffer, which are the ingredients commonly used, there are other very fine ones, which care and skill may prepare: very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brass or copper, and a sky colour from silver; and a much finer one from the common small garnets of Bohemia, which are of little value. The gems also afford glorious colours like their own. *Neri's* Art of Glass, p. 136.

The fine blue from silver is, probably, only from the small quantity of copper used in the alloy.

A very singular and excellent way of making the *paste* to imitate the coloured gems, is this: take a quantity of saccharum saturni, or sugar of lead, made with vinegar in the common way; set it in sand, in a glass body well luted from the neck downwards; leave the mouth of the glass open, and continue the fire twenty-four hours; then take out the salt, and if it be not red, but yellowish, powder it fine and return it into the vessel, and keep it in the sand-heat twenty-four hours more, till it becomes as red as cinnabar. The fire must not be made so strong as to melt it, for then all the process is spoiled. Pour distilled vinegar on this calcined salt, and separate the solution from the dregs; let the decanted liquor stand six days in an earthen vessel, to give time for the finer sediment to subside; filter this liquor, and evaporate it in a glass body, and there will remain a most pure salt of lead; dry this well, then dissolve it in fair water; let the solution stand six days in a glazed pan; let it subside, then filtre the clear solution and evaporate it to a yet more pure white and sweet salt; repeat this operation three times; put the now perfectly pure salt into a glass vessel, set it in a sand heat for several days, and it will be calcined to a fine impalpable powder, of a lively red. This is called the sulphur of lead. *Neri's* Art of Glass, p. 140.

Take all the ingredients as in the common composition of the *pastes* of the several colours, only instead of red lead use this powder, and the produce will well reward the trouble of the operation, as experience has often proved.

PASTE *for angling*. There are many receipts which particular people are fond of, but the following composition seems one of the best: take equal quantities of fresh butter and sheep's suet, about half as much of good old cheese, and the crumb of an old stale white loaf, as much as will, when they are all beaten in a mortar, make the whole into a *paste*; add a little wool or tow; that it may keep the better on the hook. The place should be baited with blood and grains over night, and in the morning this *paste* will be found an excellent bait.

PASTES *for birds*, a general sort of food made by the people who breed up birds from the nest, and suiting almost all kinds.

It is made in the following manner: grind half a peck of large beans, well dried, to a very fine meal; take of this meal two pounds, of the best sweet almonds blanched one pound; these must be well beat together in a mortar, till perfectly mixed; then to a quarter of a pound of fresh butter, in a saucepan well tinned, add the *paste*, and mix all well together over a charcoal fire, stirring it as it boils with a wooden spoon; then add the yolks of four eggs, and a little saffron, and finally a small quantity of the finest virgin honey. When these are well incorporated, and are tolerably thin and without lumps,

the whole is to be poured into a colander made with fuch holes as will let the compofition pafs thro': if any of it is fo ftiff that it will not go thro', it muft be beat again in a mortar, and by that means made fit to pafs the holes and mix with the reft. When the whole is done, it is to be put into a pot, and a little clarified honey being melted and poured on it, it will keep very well for fix months or longer.

PASTELL, (*Cycl.*) a name given by fome to the *ifatis*, or *woad*. See the articles WOAD and ISATIS.

PASTERN (*Cycl.*)—PASTERN-*joint*, in the manege, called alfo the *fetlock* of a horfe's leg, is the joint above the *paftern*, which ferves for a fecond knee in each fore leg, and a fecond ham or hough, to each hinder leg. The *fetlock* is apt to be cut by the fide of one of the fhoes; and when that happens, we fay, a horfe cuts or interferes. Sprains happen upon the *fetlock*, and cratches above it behind.

PASTINACHA, *parfnep*, in botany, the name of a genus of plants, the characters of which are thefe: The flowers are difpofed in umbells, and are of the rofaceous kind, being compofed of feveral petals arranged in a circular order upon a cup; which finally becomes a fruit compofed of two large oval, flattifh, marginated feeds; which frequently depofit their covering. To this it may be added, that the leaves are large and alated.

The fpecies of *parfnep*, enumerated by Mr. Tournefort, are thefe: 1. The great broad-leaved garden *parfnep*. 2. The broad-leaved wild *parfnep*. 3. The largeft wild *parfnep*, called by authors *panax cofterium*s. *Tourn.* Inft. p. 319. See the article PARSNEP.

PASTINACHA *marina*, in zoology, the name of a fifh, called in Englifh the *poifon fifh*, or *fierce flaw*. It is one of the flat cartilaginous fifhes, and fomething like the common fkate. It is very broad, and is thick in the middle, and thin at the edges; fmooth fkined, and yellowifh on the back, and of a filvery white on the belly; but the ridge, or middle part of the back and the tail, are blue. It has only two fmall fins, which furround the anus; the whole body is, however, thinned off at the edges into a fort of fins. Its fnout is very fharp; its eyes large and protuberant; its mouth is fmall, and without teeth; but its jaws are rough and rugged. Its noftrils are very large, and placed near the mouth, and of a lunulated figure. Its tail, in which all its poifon is lodged, is long, fmooth, and round, with a thorn, or dart, of a finger's length, toothed on each fide like a faw, with the teeth ftanding upwards, or toward the head. This is placed at the diftance of about one third of the length of the tail; and that from this place grows very flender, and ends in a very flender point. It grows, fometimes, to ten pound weight; and when the tail is cut off, is commonly fold in the markets in Italy and elfewhere. See Tab. of Fifhes, Nº 6.

Authors give us many remarkable accounts of the poifon of this fifh, which it communicates to animals by the ftroke of its tail. They mention alfo two kinds of it; that is, befide the ordinary fpecies which is fmooth, another called the *paftinacha marina afpera*, which is rough and prickly. *Jonfon*, de Pifc. p. 19.

PASTOPHORI, Παστοφοροι, among the antients, priefts whofe bufinefs it was, at folemn feftivals, to carry the fhrine of the deity, when they were to pray to him for rain, fair weather, or the like. *Pitifc.* in voc.

PASTOPHORIA, in antiquity, the apartments near the temples where the *paftophori* were lodged.

Clemens Alexandrinus [a], defcribing the temples of the Egyptians, fays, that after having paffed through magnificent courts, you are conducted to a temple, which is at the farther end of thefe courts, and then a *paftophorus* gravely lifts up the veil which is at the door, to fhew you the deity within; which is nothing but a dog or a cat, or fome other animal. Thefe *paftophori* alfo fupported the fhrine, or niche of thefe ridiculous divinities, when they were carried in proceffion. Apuleius [b] fpeaks of the *paftophori* that carried the Syrian goddefs. —[[a] *Clem. Alex.* l. 3. c. 2. Pædag. [b] *Apul.* Afin. Aur. l. 10. c. 11. *Calm.* Dict. Bibl. in voc. *paftophoria*.]

In the temple of Jerufalem there were two courts furrounded with galleries, and all round about were feveral lodging rooms for the priefts, and to lay up wood, wine, oil, falt, meal, fpices, incenfe, veftments, valuable veffels, and provifions neceffary for the facrifices and lamps; as alfo for the fupport and maintenance of priefts. Vid. 1 *Chron.* ix. 26, 33. *Ezek.* xl. 17, & 18. 1 *Chron.* xxvi. 16. *Calmet.* Dict. Bibl.

PASTOR (*Cycl.*)—PASTOR *pifcis*, in zoology, the name of a fifh of the mullet kind, caught in the American feas and rivers, and efteemed a very well tafted one.

It is of the ufual fize of our river-trout, and not unlike that fifh in fhape. Its fcales are large and of a filvery white; and are ranged in the fame order that thofe of the perch are, with greyifh lines between the feveral arrangements. It has feven fins all very large, efpecially that on the back; and its tail is remarkably forked. All the fins are white, and the coverings of the gills are fcaly, not bony, as in moft other fifhes; whence it has been fuppofed to have no gills. *Marggrave's* Hift. of Brafil.

PASTORAL, in the Italian mufic, an air compofed after a very fweet, eafy, gentle manner, in imitation of the airs fhepherds are fuppofed to play.

PASTURE (*Cycl.*) — *Pafture-land* is of fuch advantage to hufbandry, that many prefer it even to corn-land, becaufe of the fmall hazard and labour that attends it, and as it lays the foundation for moft of the profit that is expected from the arable-land; becaufe of the manure the cattle afford which are fed upon it. Where dung is not to be bought, as is often the cafe in places diftant from large towns, the farmer is forced to proportion his arable to his *pafture*-land, in fuch manner, that the cattle fed on the latter may be fufficient for a fupply of dung, fo neceffary for producing the fruits of the former.

Pafture-lands are of three kinds: 1. The uplands: thefe lie fo high as not to be overflowed by rivers, or land-floods. 2. Thofe low lands which lie near rivers and fens. And 3. Thofe that lie near the fea. *Mortimer's* Hufbandry, p. 15. See the articles UP-LAND, MARSH-LAND, &c.

Pafture-land requires the refrefhment of dung, as well as the arable or corn-land; but there is to be a difference made in the laying it on and fpreading it. A harrow performs the office of fpreading the dung on ploughed lands; but the beft contrivance for paftures, is, to lay the dung in fmall heaps, and draw over it a gate ftuck full of bufhes. All dung that is laid on *pafture*-land, muft be laid on in winter, that the rains may wafh its fatnefs into the ground before the fun fcorches it, or evaporates its goodnefs. Fine mould mixed with the dung, and fpread with it over the land, is very good for *paftures*; for it is wafhed down to the very roots of the grafs, and gives them a new and fine foil juft in thofe places where it is moft wanted.

The beft manure for *pafture*-land, is, the rotten bottoms of old hay-ftacks; for thefe moulder away into a very rich foil, and are always full of vaft quantities of feed, fallen at times from the hay, which all grow when fpread on the ground: and thus new nourifhment, and a new fet of plants are given at once to the exhaufted ground. But as particularly ufeful as this is for *pafture*-ground, it is as improper for corn-land, and fhould by no means ever be fuffered to mix with the manure for thofe grounds; as it will then raife grafs and other plants, which tho' of ufe in the *pafture*, are weeds among the corn. *Mortimer's* Hufbandry.

Artificial PASTURE. As to the difference of the quantity of *artificial pafture* made by dung without tillage, and that made by tillage without dung, the latter is many times greater, as has been proved by repeated experiments on unploughed land, whereon a dunghill had lain for two or three years, and being then removed, was planted with turneps; and at the fame time a tilled land contiguous thereto, was drilled with turneps, and horfe-hoed. The other being hand-hoed, feemed to profper beft at firft, but, in fine, it did not amount to a fifth part of the tilled and horfe-hoed land, either in bignefs or in crops; fo that the benefit of the dung and hand-hoe was inconfiderable in comparifon of the plough and horfe-hoe. The little quantity of *artificial pafture* raifed to the other, was only near the furface, and did not reach deep enough to maintain the turneps till they arrived at the fifth part of the growth of thofe which were placed in an *artificial pafture*, that reached to the bottom of the common bed of mould.

Another proof of the fame kind, is, that feveral lands of turneps drilled on the level, and at three foot rows, ploughed, and doubly dunged, and alfo horfe-hoed, did not produce nearly fo good a crop of turneps as fix foot ridges adjoining horfe hoed, tho' no dung had been laid on them of many years.

In this cafe, there was no other difference but that the three foot rows did not admit the hoe-plough to raife half the *artificial pafture* as the fix foot rows did. The dung ploughed into the narrow intervals before drilling, could operate no farther with any great effect, than the hoe-plough could turn it up and help its pulverization. Upon the whole, dung without tillage can do very little; with fome tillage it does fomething, with much tillage it pulverifes the foil in much lefs time than tillage alone can do it in; but tillage alone, in more time, can pulverife it as well. Much of the dung commonly ufed on fields is to be faved on this principle; a little more hoeing between the rows of the plants fupplies the place of it, and is done at much lefs expence than that of fo much manure, of the hands neceffary to lay it on, and the carriage. *Tull's* Horfe-hoeing Hufbandry.

PASTURE *of plants*. Plants themfelves make the *pafture* for animals; but before they are in a condition to give nourifhment to them, they muft themfelves receive that nourifhment from the earth. This *pafture* of plants feems lodged out of the way of our fenfes; and the ignorance in regard to this, feems the reafon why hufbandry, tho' one of the moft ufeful and neceffary arts to man, has been treated in a very fuperficial manner by the authors who have written of it. The food, or matter of increafe of plants, is earth; and, therefore, that may be properly enough called *their pafture*.

This *pafture* is the inner, or internal fuperficies of the earth; or, which is the fame thing, it is the fuperficies of the pores, cavities

cavities and interſtices of the divided parts of the earth: theſe are of two kinds; the one natural, the other artificial. By nature the whole earth, or ſoil, is compoſed of parts; and if theſe had been in every place abſolutely joined, it would have been without interſtices or pores, and would have had no internal ſuperficies, or *paſture* for plants; but ſince it is not ſo denſe, there muſt be theſe interſtices at all thoſe places where the parts remain ſeparate or divided. Theſe interſtices, by their number and largeneſs, determine the ſpecific gravity or true quantity of every ſoil; the larger they are, the lighter is the ſoil, and the inner ſuperficies anſwers accordingly. The mouths of the veſſels deſtined to take in the food or nouriſhment of the plant, are all ſituated on the convex ſurface of the roots; and theſe take their pabulum or food, which is extremely ſmall particles of earth, blended with a due proportion of water, from the ſuperficies of the pores or cavities within which the roots are included.

It is certain that the earth is not diveſted of this pabulum by any other means than by the roots of plants, or by actual fire; for where no vegetables are ſuffered to be, the ground will always grow the richer.

Plough it or harrow it as oft as you pleaſe; let it be expoſed to the ſun in horſe-paths all the ſummer, and to the froſts all the winter; let it be covered by water at the bottom of ponds and ditches, or grind it to fine powder; the longer it is expoſed or treated by any or all of theſe methods, or any other poſſible way, except actual fire be uſed, the more fertile it will be. Thoſe particles which are the pabulum of plants are ſo extremely minute and light, as not to be ſingly attracted to the earth, if ſeparated from thoſe parts to which they adhere, or with which they are in contact. They adhere in the earth like duſt to the ſurface of a ſmooth clay, which, tho' you turn it up and down, ſtill remains in its place, as theſe particles do to thoſe parts of the earth, till removed by ſome external agent. The proper agent for this purpoſe is the root of a plant, but this cannot act upon them unleſs they are firſt moiſtened by water; which helps to looſen them, and goes with them into the mouths of the veſſels in the root. It is neceſſary alſo that the nitre of the air come in contact with the matter of this pabulum, in order to relax and render it fit to be ſeparated and imbibed by the roots of thoſe plants which are in the way of it.

As to the ſize of the particles of this pabulum of plants, it is not unlikely that the roots may take in no groſſer ones than thoſe on which the colours of bodies depend; but to diſcover the magnitude of theſe corpuſcles, Sir Iſaac Newton thinks will require a microſcope that will repreſent things five or ſix hundred times bigger than they appear to the eye at a foot diſtance, and that with ſufficient diſtinctneſs.

We are well aſſured, that the fine particles of the food of plants, after they have been received into the bodies of plants, do perſpire thro' their pores in a large quantity, and fly off into the air: this affords us a proof, that they are not to be ſeparated from the parts of the earth with which they are in contact, otherwiſe than by means of plants; for if they could, then all our ſtirring and digging the earth would make it the poorer, by giving them occaſion to evaporate; the contrary of which is found by experience.

Water alone affords in appearance nouriſhment to plants, ſince they will grow in water; but this water is allowed never to be free from earth, and that makes it ſo very nutritive to plants, even when freſh rained down. This is the earthy matter, which is properly the pabulum or food of plants, which is continually in great abundance evaporated from plants and trees into the air, and in a manner fills the whole atmoſphere about them; this is met by and embodied in the watry vapours in their aſcent, and again brought down to the earth in ſhowers of rain with them.

Hence it is no wonder, that rain-water proves ſo very nutritive to plants, ſince it contains the very matter of their food, ready ſeparated from the reſt of the earth, and mixed in that very vehicle with, and by means of which alone it can be received into the bodies of plants, through the mouths of the veſſels of their roots.

The pores, cavities, and interſtices of the earth being of two ſorts, *viz.* natural and artificial, the one affords the natural, the other the artificial *paſture* for plants; all depending on the different nature of the internal ſuperficies of the earth. *Tull's* Horſehoeing Huſbandry. See the article *internal* SUPERFICIES.

PATA, in zoology, the name by which the Portugueze in Braſil call a large and very beautiful American duck, known among others by its Braſilian name, *ipecati-apoa*. It is nearly of the ſize of the gooſe. See IPECATI-*apoa*.

PATÆCI, in mythology, images of certain gods carried by the Phœnicians on the prows of their gallies. *Hoffm.* Lex.

Herodotus, lib. 4. calls them Παταικοὶ. The word is Phœnician, and derived from *pethica*, i.e *titulus*. See *Bochart's Chanaan*, l. 2. c. 3. but Scaliger does not agree. Morin derives it from Πίθηκος, monkey, this animal having been an object of worſhip among the Ægyptians, and hence might have been honoured by their neighbours. Vid. *infra*.

Mr. Elſner [a] has lately obſerved, that Herodotus does not call the *patæci*, gods; but that they obtained this dignity from the liberality of Heſychius and Suidas, and other antient lexicographers, who place them at the ſtem of ſhips, whereas Herodotus placed them at the prow. Scaliger, Bochart, and Selden [b], have taken ſome pains about this ſubject. [[a] In Mem. de l'Acad. de Berlin, Tom. 2. p. 379. [b] *Gale*, Not. ad Herodot.]

Mr. Morin has alſo given us a learned diſſertation on this head, in the Memoires de l'Acad. des Inſcript. and Belles Lettres, Tom 1. but Mr. Elſner thinks it defective in point of evidence. He alſo rejects the etymologies of Bochart, Scaliger, and Morin; he himſelf thinks that the *patæci* were the ſame as the Dioſcuri [c], not Caſtor and Pollux, invented by the Greeks, but the Dioſcuri of oriental and higher antiquity. [[c] Children of Jupiter, Διοσκουροι, or Διοσκοροι; for we may meet with both. See *Hemſterhuys* in Lucian. Dialog. Deor]

Herodotus ſays, the *patæci* reſembled the little ſtatues of Vulcan. Pauſanias tells us they were about a foot high. They were eſteemed the protectors of navigation. See *Eſner*, loc. cit.

PATAGONULA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is an extremely ſmall perianthium, divided into five ſegments, and remains after the flower is fallen. The flower conſiſts of a ſingle petal, with ſcarce any tube, the margin of which is divided into five acute oval ſegments. The ſtamina are five filaments of the length of the flower. The antheræ are ſimple. The germen of the piſtil is oval and pointed. The ſtyle is ſlender, and ſlightly bifid; its ramifications are alſo bifid again. This is of the ſame length with the ſtamina, and remains when the flower is fallen. The ſtigmata are ſimple The fruit is an oval and pointed capſule, ſtanding on a large cup, made up of five long ſegments emarginated, or rimed round their edges. The ſeeds of this plant are yet unknown; but the conſtruction of the cup in which the capſule ſtands is alone a ſufficient diſtinction for this genus. *Linnæi* Gener. Plant. p. 66.

PATANGHI, in botany, a name by which ſome authors have called the tree whoſe wood is the logwood, uſed in dying and in medicine. *Herm.* Muſ. Zeyl. p. 47.

PATE (*Cycl.*)—PATE, in zoology, a name given by the people of the northern counties of England to the *badger*. See the article TAXUS.

PATEE (*Cycl.*) in heraldry, a term uſed by ſome to expreſs a ſort of irregular line, differing from the indented, ingrailed, and all the other regular and common lines, and called by ſome the dovetail line.

It is ſomewhat like the joint called by our joiners by this laſt name, but it is not in general uſe, and is by ſome reckoned among what the French call the *clatte*, a term they have for ſuch irregular lines as they find in old engravings or figures, tho' not in uſe in any arms preſerved to this time. *Niſbet's* Heraldry. See CLATTE.

PATELLA, (*Cycl.*)—This is a ſmall bone, ſituated above the ſpine of the tibia, reſembling a large cheſnut. It is about half as thick as long, and its length and breadth are nearly equal. It is divided into a baſis, apex, and two ſides, one convex, the other concave. The baſis is the ſuperior and thickeſt part of the bone, and is marked with a very conſiderable muſcular impreſſion, which runs down for a little way on the convex ſide. The apex is obtuſe, and ſerves for the inſertion of a ſtrong ligament, which ties the *patella* to the ſpine of the tibia. The anterior ſide is convex, with ſome ſmall inequalities and furrows upon it. The poſterior ſide is concave, covered with a cartilage, reaching near the apex, and terminating at an unequal cavity or foſſula, which is an impreſſion for the ligament already mentioned. This cartilaginous ſide is parted in two by a ridge which goes between the baſis and apex, and the two parts are exactly ſuited to the pulley of the os femoris, the external part being broader than the internal, which is likewiſe obſervable in the pulley. The *patella* remains long cartilaginous, and in oſſifying it becomes entirely cellular, except the ſurfaces of its two ſides and the impreſſions. It is connected with the tuberoſity of the tibia by a thick ſhort ligament; and, indeed, it may be looked upon as belonging in a particular manner to the tibia, or as a moveable olecranum; which again may be looked upon as a fixed *patella*. *Winſlow's* Anat. p. 94.

Fracture of the PATELLA. The *patella* or *knee-pan* is much more ſubject to a tranſverſe fracture than to one in any other direction. The longitudinal fracture of this bone happens more rarely, but when it does, is much more eaſily cured; becauſe the fragments of the bone in this caſe, generally keep in their right places, but when the bone is broken not only tranſverſely, but into ſeveral pieces, the caſe is yet more difficult and dangerous. The cure of this fracture muſt be attempted in this manner: in a longitudinal or perpendicular fracture, the patient muſt be laid upon his back, and, extending the foot, the ſurgeon muſt replace the fragments on both ſides with the preſſure of his hands, binding them up carefully with the uniting bandage; which muſt be applied in this caſe in the ſame manner with that uſed in large wounds in the belly or forehead. But when the *patella* is broken tranſverſely, or into ſeveral pieces, the patient being laid in the ſame poſture, and extending his foot as before, the ſurgeon is with great care

care to endeavour with the palms of both hands, affifted by his fingers and thumbs, to bring together and replace the fragments in their natural fituation; and when that is done, they muft be retained firmly together, by means of a plaifter made in form of a half moon, or properly perforated, and then the foot and leg are to be bound up, and placed fo that they cannot be eafily moved: but to prevent the bone from being difplaced again, the patient muft not ufe his leg till after the ninth or tenth week. *Heifter*'s Surg. p. 134.

PATELLA *luxated*. The *patella* is moft ufually luxated either on the internal or external fide of the joint, tho' phyficians give accounts of its being fometimes luxated both above and below it. Whenever the knee itfelf is perfectly luxated, the *patella* can fcarce avoid being difplaced at the fame time, becaufe of its ftrong connection to the thigh and to the tibia.

The reduction of a luxated *patella* is ufually no great difficulty. The patient is to be laid flat on his back upon a table or bed, or upon an even floor, fo that his leg may be pulled out ftreight by an affiftant; when this is fufficiently extended, the furgeon muft grafp the *patella* with his fingers, and afterwards, by the affiftance of his hand, prefs it ftrongly into its proper place. This may be alfo poffibly effected while the patient ftands upright: when this is done, there remains nothing but carefully to bind up the part, and let the patient reft for fome days; fometimes gently bending and extending his leg in the mean while, that it may not become ftiff. *Heifter*'s Surg. p. 171.

PATELLA, the *limpet*, in natural hiftory, the name of a genus of fhell-fifh, the characters of which are thefe: It is an univalve fhell, of a gibbous fhape, always fixed in its natural ftate to a rock or to fome other hard body, and having its apex or fummit fometimes fharp pointed, fometimes obtufe, fometimes ftreight, fometimes crooked, fometimes whole, and fometimes perforated. There are feveral fpecies of each of thefe kinds. See Tab. of Shells, N° 1, 2.

Of the *limpet* with a fharp pointed fummit, there are the following fpecies: 1. The pyramidal mucronated *limpet*. 2. The pyramidal furrowed *limpet*. 3. The grey *limpet*: this, tho' a plain fpecies in its rough ftate, is very beautiful when its outer coat is taken off by polifhing. 4. The ten-ribbed *limpet*.

Of the *limpets* with depreffed heads are the following: 1. The furrowed marbly *limpet*. 2. The nipple *limpet*: this refembles the nipple of a woman's breaft. 3. The ftriated *limpet*, jagged at the edge. 4. The finely ftriated *limpet*: the lines in this fpecies are as fine as hairs. 5. The ftriated and prickly *limpet*: this, when polifhed, makes a very different figure, and is like a fhield with variegations of colour like thofe of tortoife-fhell. 6. The red-fpotted *limpet*. 7. The red and white ftriped *limpet*.. 8. The goat's eye *limpet*, fo called from its variegations on its infide, reprefenting the eye of a goat. 9. The carbuncle *limpet*, fo called from a glowing red in the fhell: this is beft feen when the fhell is polifhed, and held againft a ftrong light. Hift. Nat. Eclairc, P. 2. p. 237.

Of the *limpets* with perforated tops we have the following fpecies: 1. The cancellated open *limpet*. 2. The high-ridged *limpet*. 3. The fine ftreaked *limpet*, with ftreaks like hairs. 4. The oblong *limpet*, with two holes: this, when its furface is taken off by polifhing, makes the fine red *limpet* feen in many collections; and the fame fhell, with the coat juft erafed from the furface, fo as not to penetrate to the red part, makes the grey *limpet* with the double aperture, alfo frequently feen in the cabinets of collectors. Hift. Nat. Eclairc, P. 2. p. 238.

The Latins call this fhell *patella* from its refemblance to a difh, and the Greeks named it *lepas*, as if they meant to call it a fcale or flake of the ftone. Indeed this fifh always adheres to rocks, as if a part of the ftone; and the rock ferves it in the place of a fecond fhell, to defend it from the injuries of the weather. Aldrovand and Rondeletius have carried this thought fo far, as to place the *limpet* among the bivalve fhells; but no author has followed them in this. Bellonius obferves, that when they are found adhering to ftones in great numbers, as they frequently are, they refemble the heads of fo many large nails driven into the ftone. Columna diftinguifhes four kinds of the *limpet*: the firft he calls the common *limpet*, becaufe it was moft common of all the fpecies about Naples where he wrote; this is of an oval figure and of an afh colour. The fecond he calls the great exotic *limpet*: this he had from Spain; it was large and hard, and had feveral ribs, which ended into many dents at the verge. The third he calls the wild *lepas*: this is a fmall *limpet*, of an irregularly oval figure, and of an afh colour, and has a hole at the top, out of which the excrements are evacuated. The fourth kind he calls the royal *limpet*, becaufe he fays it is worthy to come to the table of a king: this is rough and has feveral holes at the top. The number of holes in the laft is either accidental, or elfe it is a fpecies of *limpet* unknown at prefent; the others may be eafily found among the already mentioned fpecies. *Bellonius. Fab. Columna* Aquat. et Terreft. p. 11.

Some *limpets* are concamerated within, or formed into feveral diftinct apartments. Of thefe there are the following fpecies: 1. The oblong beaked *limpet*. 2. The rounded arched *limpet*. 3. The large Chinefe *limpet*. 4. The *limpet* with a ftyle rifing within it from the bottom. 5. The irregularly fhaped longed beaked *limpet*. 6. The femi-concamerated *limpet*: this has feven remarkable ribs running from its top, which terminate in feven fpines at the bafe. This fpecies is hence radiated like a ftar at the verge, and is thence called by fome *aftrolepas*.

Of the *limpets* with crooked tops are the following fpecies: 1. The long and crooked headed *limpet*. 2. The red nipple *limpet*. 3. The grey *limpet*, of an elegant rofe colour within. 4. The *limpet* with a crooked top ending at the limb, and making the whole fhell thus reprefent, in fome meafure, a deeply ftriated pecten or fcallop: this is hence called by fome *concholepas*. 7. The lefs ftriated *concholepas*.

PATELLA, in the hiftory of infects, a name given by Lifter and fome others to a certain little hufk or fhell found on the bark of the cherry, plum, and rofe trees, and fome others, containing an animal within, and ufeful in colouring. Thefe *patellæ* are of a globular form, except when they adhere to the tree, and are of a fhining chefnut colour in moft kinds. The hufk itfelf ftrikes a very fine crimfon colour on paper, and within it is found a white maggot of no value: this, in time, hatches into a very fmall but beautiful bee. The whole fize of this bee is not more than that of half the body of an ant. They have the fting of bees, and the three fpots placed in a triangle on the forehead, which are fuppofed to be eyes. They are black, and have a large round whitifh or pale yellow fpot upon the back. The upper pair of wings are fhaded and fpotted, but the under pair are clear.

The fhells or hufks deferve a trial, to find whether the colour they yield might not be brought to ufe; it is to be obferved, that the deepeft coloured hufks afford the fineft and deepeft purple: they muft be alfo ufed while the creature contained in them is in the maggot form; for when it is changed into the bee ftate the fhell is dry and colourlefs. Dr. Lifter, who firft obferved thefe *patellæ*, went fo far on the comparing them with the common kermes, as to declare that they were of the fame nature with that production; but his hiftory of their being the workmanfhip of a bee, to preferve her young maggot in, is not agreeable to the true hiftory of the kermes; for that is an infect of a very peculiar kind. This author has been too juftly cenfured for his precipitancy of judging of things, and perhaps has fallen into an error by means of it here.

It is very poffible that thefe *patellæ* may be the fame fort of animal with the kermes, but then it produces its young within this fhell or hufk, which is no other than the fkin of the body of the mother animal; but as there are many flies, whofe worms or maggots are lodged in the bodies of other animals, it may be, that this little bee here defcribed may love to lay its egg in the body of the proper infect here defcribed, and the maggot hatched from that egg may eat up the proper progeny, and undergoing its own natural changes there, iffue out at length in form of the bee. This may have been the cafe in fome few which Dr Lifter examined, and he may have been mifled by this to fuppofe it the natural change of the infect. Phil. Tranf. N°. 72.

PATELLA *fera*, the wild *limpet*, a name very improperly given by Rondeletius and Aldrovand to the *auris marina*, or *concha veneris*. This is by no means of the *patella* kind. See the article EAR-*fhell*.

PATENT-*leaf*, among botanifts. See LEAF.

PATER *patratus*, among the Romans, the firft and principal perfon of the college of heralds, which formed a kind of board or council to examine the differences that arofe between neighbouring ftates, and endeavour amicably to accommodate the fame. *Danet* in voc.

PATETÆ *uvæ*, a name given by the antients to grapes dried on the vine. See PATETHISÆ.

PATETHISÆ *uvæ*, a name given by the antients to grapes which were fuffered to remain on the vine till they were greatly dried and withered. They were alfo called *patetæ uvæ*, and were fuffered to hang thus to make a peculiar wine called *paffum*.

PATH (*Cycl.*)—PATH-*fly*, the name given by us to the fly called in Latin *humifuga*; it is found in foot-paths, and fuppofed to live by fucking the ground. It is of a grey colour, ftreaked with dufky white. See HUMISUGA.

PATHOGNOMIC *figns*, in medicine. See ASSIDENT.

PATIENCE, in botany, the name by which fome people call the monks rhubarb; but the French, from whom we have borrowed the word, mean by it all the fpecies of the *lapathum* or dock kind. See the article LAPATHUM.

PATIENTIÆ *mufculus*, in anatomy, a name given by Spigelius to a mufcle of the fhoulder, which he alfo calls by the more expreffive name of *fcapulam attollens*. The French call it the *releveur propre de l'omoplate*, and Albinus, Morgagni, Cowper and others *levator fcapulæ*.

PATIN-*fhoe*, in the manege, a kind of horfe-fhoe, under which is foldered a fort of half ball of iron, hollow within. It is ufed for hip-fhot horfes, and put upon a found foot, to the end, that the horfe not being able to ftand upon that foot without pain, may be conftrained to fupport himfelf upon the lame foot, and fo hinder the finews to fhrink, and the haunch to dry

dry up. We likewise clap *patin-shoes* upon horses that are sprained in the shoulders.

PATIS, in zoology, the name of a small sea-bird, described by Oviedus, and seeming to be the same with the stormfink described by Hoier in his epistle to Clusius. It is a little larger than our sparrow, and skims the surface of the water very nimbly, and is supposed a fore-runner of storms.

PATLAHOCA, in botany, the name given by some authors to the tree which produces the resin, commonly called *gum-copal*. *Hernand*, p. 46.

PATREZ, a name for a sort of vermichelli, a paste made of flour and water, and formed into beads. This and all other kinds of vermicelli are often stained with saffron.

PATRICIDE, *patricidium*, the same with *parricide*. See the article PARRICIDE, *Cycl.*

PATRIMI *and* MATRINI, among the Romans, children whose father and mother were both living.

It was by a certain number of these that hymns were sung to supplicate the gods. V. *Liv.* 37, 3.

PATTALIA, in natural history, a word used by Aristotle and the rest of the old Greek writers, to express a stag or deer of two years old. The interpreters of Aristotle have generally rendered this by the Latin word *subulo*; but that is of a very vague and uncertain sense, and this Greek word of a very determinate one, never being used to express any animal except the stag at this age. Pliny and the Roman authors in general use the word *subulo*, indeed, sometimes for a young stag; but they oftener use it to express that imaginary beast the oryx or unicorn. Pliny says, that nature has given this animal *cornua simplicia*, single horns, as it is generally understood to mean; but the phrase may as well be translated plain, uniform, and unbranched horns. The word may have been thus used to distinguish the horns of this creature, whatever it was, from the stag, and not to imply that each of them had only one horn: in this sense, however, it is no proper translation of the word *pattalia*, which signifies a stag of a certain age, not any other animal.

PAVANA, in botany, the name of the plant which produces the *grana tiglia* of the shops. It is a species of *ricinus*. *Jons.* Dend. p. 458. See RICINUS.

Pavana-wood, when fresh, operates very violently, both by vomit and stool: when dried, it is much more gentle, never vomiting at all; but at present it is scarce heard of in the shops.

PAVIA, in botany, the name of a genus of plants described by Boerhaave and Linnæus, the characters of which are these: the perianthium consists of one leaf, and is coloured, of an oval figure, and divided into five obtuse segments at the edge. The flower consists of five oval petals, the upper ones longer than the others; the longest of all are very long, and are inserted into the cup. The stamina are eight subulated filaments, somewhat crooked, and of the length of the flower. The antheræ are roundish, the germen of the pistil is of an oval figure, the style is subulated, and the stigma acute. The fruit is a coriaceous turbinated capsule, of an obtusely four square form, composed of four valves, and containing four cells; in each of which is contained a single roundish seed. *Linnæi* Gen. Pl. p. 158.

PAVICULA, among the Romans, a rammer, or instrument for beating down and levelling a spot of ground.

It consisted of a block of wood one foot long and half a foot thick, with a long handle. *Pitisc.* in voc.

PAVILIONS, among jewellers, the under sides and corners of the brilliants, lying between the girdle and the collet. *Jeffries* on Diamonds. See GIRDLE, *&c.*

PAULA *gunda*, in natural history, a name given by the people of the East Indies to a species of fossil of the *osteocolla* kind, found in some springs, the waters of which are loaded with spar. These people use it in medicine, giving it in milk for gonorrhœas, and that with good success.

PAULADADUM, a name given by some authors to the medicinal earth of the island of Malta, called *terra melitensis*, and *gratia sancti Pauli*. Some have given this name also to a species of white bole found in some parts of Italy, which is made into cakes, and sealed, and serves in the place of this and other white earths.

PAULINIA, in botany, the name of a genus of plants, according to Linnæus, taking in the *seriana* and the *cururu* of Plumier. The characters are these: the perianthium is composed of four oval and expanded leaves, and remains when the flower is fallen. The flower consists of four oblong and cordated petals; these stand expanded, and are of twice the bigness of the leaves of the cup. The stamina are eight simple and short filaments. The antheræ small. The germen is three cornered, obtuse, and of a turbinated form. The styles are capillary, and are three in number, and very short. The stigmata are simple and broad. The fruit is a large three cornered capsule, composed of three valves, and containing three cells, in each of which is a single seed of an oval figure. The difference between the *cururu* and *seriana* of Plumier is, that the *seriana* produces its seeds in the base of the cells, and the *cururu* in the cells of them. *Linnæi* Gen. Pl. p. 170. *Plumier* Gen. 35.

PAUNCH, or PANCH, on ship-board, those matts made of sinnet, which are made fast to the main and fore yards, to keep them from galling against the mast.

PAVO, (*Cycl.*) The *peacock*, in the Linnæan system of zoology, makes a distinct genus of birds of the *gallina* kind; the distinguishing characters of which are, that the feet have each four toes, and the head is adorned with an erect ornament of feathers, in form of a plume. *Linnæi* System. Naturæ, p. 47.

PAVO, in ichthyography, the *peacock-fish*, one of the larger species of the *turdus*, or *wrasse*, but of a middle nature between the long and the flat bodied kinds. Its usual standard, as to size, is about three pounds weight; and its colour on the back a mixture of blackish and a dusky blue: the blue is disposed in three or four longitudinal parallel lines, on a dusky blackish ground; about the head and gills the blue lines are more bright and numerous. Its lower jaw is almost wholly blue, and its belly is of a fine saffron colour or reddish yellow. It has thick lips, and very sharp tho' not very large teeth. Its back fin is, on the anterior part, of a fine deep blue, with an edge of purple, and sometimes of yellow; and the rest of the fin is red at the bottom and yellow at the top, and in the middle is finely variegated with blue spots. The foremost nerves of the back fin are rigid and prickly, and have soft and flexile rays accompanying them beyond the limb or edge of the fin, and of more than their own length. Its gill-fins are a mixed red and yellow, and its belly-fin behind the anus of a pale flesh colour, with a variegation of blue and yellow. The other belly-fins are of the same colours, and the tail is wholly blue. It is a most remarkably beautiful fish, and from the spots and variegations of its fins has obtained its name. *Ray's* Ichthyol. p. 321. See Tab. of Fishes, N° 59.

PAVONIUS-*lapis*, the *peacock stone*, a name given by Ludovicus Dulcis, and other writers of his time, to a stone of which they say many idle things, such as its having the virtue of gaining a person's love to another, and the like. They have left us no description of it, but probably it was one of the variegated agates.

PAURAEDRASTYLÆ, in natural history, the name of a genus of crystals. The word is derived from the Greek παῦρος, a few, ἕδρα, a side or plane, the privative particle α, not, and στῦλος, a column; and expresses a fossil composed of but a few sides or planes, and having no column.

The bodies of this genus are crystals composed of two pyramids joined base to base, without the intervention of a column; these being both hexangular, and consequently the whole body composed only of twelve planes; the others of the same structure being composed of sixteen. *Hill's* Hist. of Fos. p. 167.

Of this genus there are only four known species: 1. A whitish one with short pyramids, found in many parts of France. 2. A brown one, with long pyramids, found in great plenty in some parts of Scotland. 3. A crooked or slanting one, very clear and colourless: this is common both in the East and West Indies, but no where so plentiful as in New Spain. And, 4. A bright and blackish one, with very short pyramids: this is found in Italy, Germany, France, and England, but with us is usually met with very small. It is commonly found in clusters together. See Tab. of Fossils, Class 3.

PAUSANIA, Παυσανία, in antiquity, a festival in which were solemn games, wherein freeborn Spartans only contended. It had its name from Pausanias, the Spartan general, under whose conduct the Grecians overcame Mardonius in the famous battle of Plateæ, there being always an oration in praise of him. *Potter*, Arch. Græc B. 2. c. 20. T. 1. p. 424.

PAUSEBASTOS, in natural history, the name of a beautiful stone dedicated to Venus, and called also *paneros*. It seems to have been a beautiful agate.

PAUSICAPE, Παυσικάπη, among the Athenians, a kind of punishment. A round engine was put about the neck in such a manner, that the sufferer could not lift his hand to his head. *Potter*, Archæol. Græc. T. 1. p. 131.

PAUSIS, a word used by the old physicians for a remission in acute diseases.

PAUXI, in zoology, the name of an American bird described by Nieremberg, and seeming to be the same with the *mitu* of the Brasilians described by Marggrave, and with the *tepetototl* of Nieremberg: the whole difference is, that this, instead of a crest, has a fleshy protuberance at the basis of its bill; this is of the shape of a pear and as hard as a stone, and is of a beautiful turcois colour, or fine pale blue. *Ray's* Ornithol. p. 305. See the article MITU.

PAW, (*Cycl.*) in the manege. A horse is said to *paw* the ground when his leg being either tired or painful, he does not rest it upon the ground, and fears to hurt himself as he walks.

PAWLE, in a ship, a small piece of iron bolted to one end of the beams of the deck, close to the capstan; but yet so easily as that it can turn about. Its use is to stop the capstan from turning back, by being made to catch hold of the whelps; therefore they say, *Heave a pawle*; that is, heave a little more for the *pawle* to get hold of the whelps; and this they call *pawling the capstan*.

PAWN (*Cycl.*)—PAWN, among miners, is a pledge of money put into the bar-master's hand, at the time when the plaintiff causes

causes the bar-master to arrest the mine. *Houghton's* compl. Miner in the Explan. of the Terms.

PAYING, in the sea language. When the seams of a ship are laid over with a coat of hot pitch, it is called *paying her*; and when this is done with canvas, *parcelling*. Also when after she is graved, and her soil burned off, a new coat of tallow and soap, or one of train oil, rosin and brimstone, boiled together, is put on her; that is called *paying of a ship*. They say also sometimes, when in tacking about, a ship's sails being back stayed, fall all flat against the masts and shrouds, *she is paid*.

PEA, *pisum*, in botany. See PISUM.

Chick-PEA. See the article CICER.

PEACH, *persica*, in botany. See PERSICA.

The curious in fruits account twenty-eight sorts of *peaches*, but many of them seem very trifling distinctions. The fineness of this fruit, in general, depends on the firmness of the pulp, the delicacy of the flavour, and the thinness of the skin. A fine *peach* should be of a fine deep red next the sun, and of a pale whitish hue next the wall; and the pulp should be of a yellowish cast, and very juicy; and the stone should be small, tho' the fruit in general be large.

The varieties of the *peach* are produced like those of the finer flowers, by sowing the seeds; and tho' many raised this way will be of little value, as is also the case in flowers, yet probably among a parcel of stones, saved from the finer kinds of *peaches*, there would be some new kinds produced; which, as they were raised here, would be easily kept up in their perfection; which is not to be expected of those brought from other countries.

The best method of saving the stones is, to let some of the finest *peaches* of the best kinds hang till they drop of themselves from the tree, and then the stones should be immediately planted on a bed of light rich earth, planting them four inches deep in the earth, and at about six inches asunder. The beds should be covered, to preserve them in the winter; and in spring, when the trees come up, they must be cleared of weeds, and well watered. The next spring they should be carefully taken up, and planted in the nursery, at greater distances; and after two or three years standing here, they may be removed to the places where they are to remain; or they may at that time, when the condition of their fruit is known, be grafted on other stocks, which is the common way now used to propagate these trees.

The common method of propagating the *peach* is, by grafting. In order to this, some good stocks should be provided, which should be of the muscle, or white pear-plum. When these stocks are two or three years old, they will be strong enough to bud; and the common season for doing this is about Midsummer. The buds should be chosen from a healthy tree, which produces a great deal of fruit: they must be taken from the trees either in a cloudy day, or else in the morning or evening, when the sun has not much power: they should be then inoculated on the stocks as soon as possible, and the stocks treated with the usual care afterwards. See INOCULATION.

When these are to be transplanted where they are to remain, the most proper soil for them is, a light rich pasture-land, taken up with the turf, and rotted together, before it is to be used; and the borders to be made with this cannot be too wide, and ought to be raised five or six inches above the level of the ground; or if the soil be moist, more than that. They must be transplanted in autumn, as soon as the leaves are fallen off; and should never be set at less than fourteen feet distance from one another. The heads of the trees are then to be raised up against the walls, to keep the roots from being moved by the wind; and they should be watered at times, with a nose on the watering pot, and the water sprinkled all over them In the middle of May the new shoots are to be nailed to the wall, training them horizontally; and the foreright shoots are to be rubbed off: in October the new branches should be pruned, shortening them according to the strength of the tree; if strong, they may be left eight inches long; if weak, they should only be left five; and the same care is to be taken of them for the succeeding years.

There are two general rules always to be observed in the pruning of *peach* and nectarine trees, which are, 1. Always to have enough bearing wood. And 2. Not to lay in the branches too close to one another. All *peach* trees produce their fruit from the young wood either of the same, or at the most, of the former years shoot; for this reason the branches are to be so pruned, as to encourage them to throw out new shoots in every part of the tree: and this is to be done in May; when by pinching, or stopping the strong shoots, there may be new wood forced out in any part of the tree. This is the method of the summer pruning; the winter pruning is usually done in February or March, but is much better done at Michaelmas, as soon as their leaves begin to fall; and the wounds will then have time to heal before the severe frosts come one.

In pruning of these trees it must always be observed also, that it is best done under a wood bud, not a blossom bud; which may be distinguished by the wood buds being less turgid and longer, and narrower than the blossom bud; for if the shoot have not a leading bud where it is cut, it will commonly die down to the leading bud. In nailing the shoots to the wall, they should be placed at as equal distances as possible; and so far apart that the leaves may have room; and they must always be trained as horizontally as possible, that the lower part of the tree may be well wooded, which it will not be if the branches are suffered to run upright. *Miller's* Gard. Dict.

PEACH-*colour*, the pale red colour of the blossoms of the *peach*-tree.

To give this beautiful colour to glass, add at different times, and in small quantities, the powder of prepared manganese to the mass, for the making of lattimo, or milk-white glass while in fusion. This alone gives the *peach*-colour; but the metal must be immediately worked when of a right tinge, for the colour is very apt to go off. *Neri's* Art of Glass, p. 99. See the article LATTIMO.

PEACH-*colour*, in the manege. See BLOSSOM.

Wolf's PEACH. See LYCOPERSICON.

PEACH *flowers*. These are used as a purge for children, made into a syrup, and are by some recommended as great destroyers of worms; but there is a circumstance attending them which is little taken notice of, and yet greatly alters their virtue. The custom of gardeners is, to graft the *peach* upon the almond, or the plumtree, and the flowers partake of the nature of the stock; those which are produced on *peach*-trees grafted on plum-stocks, being much more purgative than those from almonds; the reason of which seems plainly, that the plum is a purgative fruit, the almond not at all so. The flowers of the least esteemed sorts of *peaches* are also usually found to be the best for medicinal use.

In examining these flowers, they are found to contain more than three fourths of a superfluous humidity. The buds contain a little less than the blown flowers; which is very natural to suppose, because it is their being afterwards charged with a larger portion of humidity which makes them open. The buttons, or buds of the flowers, are found on experiment, however, to be somewhat more purgative than the flowers when open.

If four pounds of these flowers are distilled in a *balneum mariæ*, they yield 12 or 13 ounces of a whitish liquor, sweet to the taste, and of an agreeable smell, resembling that of bruised *peach* kernels; and this is so strong in the water, that a few drops of it will very agreeably scent a larger quantity of any thing. If the buds are used to this purpose, instead of the open flowers, the same sort of liquor is drawn over; but it is of a somewhat coarser and more earthy smell. The residuum of these distillations put into a retort, and distilled by a reverberatory fire, gradually raised to its several degrees, yields both acid and alkaline substances; and, finally, a red spirit comes over, full of fuliginous particles, and containing some oil, part of which swims at the top of the liquor, and the other part which is heavier, sinks to the bottom. This is what a chemical analysis shews in these flowers, different from other vegetable matters. Spirits of wine draws a very weak tincture from these flowers; it is indeed much weaker than an infusion of them in common water. An infusion in water of half an ounce of fresh *peach*-flowers, or of a dram of dry ones, (for, as before observed, they contain three fourths of superfluous moisture) is a very gentle and agreeable purge. This method of infusion is much better for these and all other purgative flowers, than the taking the expressed juice; for in that case there is always a large quantity of purgative matter remaining in the residuum; which water in a warm infusion is able to take out The infusion of rose or *peach*-flowers, keeps also better than their expressed juice. The juice always turns sour very soon, but the infusion, with the common caution of pouring a little oil on the surface, will keep good even for years.

When oil is used to this purpose, there should always be care taken that it be such as does not freeze easily; for in that case the air gets in between the cake of frozen oil, and the sides of the vessel, and spoils the liquor. Oil of almonds is greatly to be prefered to oil of olives on these occasions; as it freezes with much more difficulty. Another way of preserving the infusions is, the evaporating about half the liquor; and thus they will often keep a long time: infusions keeping better than the juices of plants, seems to shew, that the former contains more of the principles than the latter.

The young leaves of the *peach* made into an infusion in the same manner as the flowers, are more purgative than they, but less agreeable; they are to be taken in the same manner. Mem Acad. Par. 1714.

PEACH-*gall-insect*, in natural history, a small *gall-insect*, found in great plenty on the *peach*-tree. It is of an ob'ong figure, flat at the belly, and prominent on the back; pointed, and not unaptly resembling in miniature a small boat turned bottom upwards. Their longer diameter is usually extended in the same direction with the length of the branch; sometimes a little obliquely, but scarce ever perpendicular to that direction Their exterior skin, the only part of them one sees, as they are attached to the tree, is very like the fine, thin, and

and glossy outer bark of many trees, as that of the cherry, &c. Their colour is usually a faint brown, sometimes it approaches to a coffee colour, sometimes to a bright chesnut, but more frequently it has something reddish in it.

The young shoots of the *peach*-tree are often covered with these on all sides; sometimes they are more distant and fewer in number. All that one sees of this kind at this season have the same lifeless appearance, and all appear perfectly motionless; but they are, however, of very different states and conditions, for usually some are in full life and vigour, others already dead, and others even the spoils of those of a former season, which remain in the places on which they died without the least sensible alteration in their appearance. Those, however, on the old wood may be judged to be dead ones, but those on the branches of the present year are usually found alive and well. The dead ones, if touched, appear as a mere film, and fall off in their scales from the branch; but the others, if crushed, yield a viscid juice, like that from the crushing of other living insects. The living animal is at this season so closely affixed to the tree, that it is not easy, by the fingers alone, to separate them without destroying them; but with caution they may be easily raised unhurt, by getting the point of a knife between them and the bark: in this case, the part of the tree from whence they are raised is seen covered with a cottony matter. The belly of the animal, which is naturally applied against this downy matter, is at this season puffed up, as it were, and seems as full as it can well hold. A little later than this season, if others are raised from the tree, it is then less easy than before to know them to be animals.

If in a fortnight, or a little more, after the time of their being as full as can be, they are removed from their place, they then make no other appearance than that of one of those dead and dry ones before mentioned, no more of the full fleshy appearance is to be seen, but they appear merely a thin flake of tortoise shell, or some other such substance, covering a vast number of small bodies close lodged together, but as loose from one another as so many grains of sand, and fall to the earth on raising the shell, unless it be done with great care.

These small bodies are somewhat reddish, and when examined by the microscope, the oval figure of them will not let one doubt but that they are eggs; and the whole insect might now appear to any one no other than a case prepared by some animal for the safety of its eggs. A little afterwards, if the animals in this state be examined, the shell is found, instead of eggs, filled with small living insects, among a quantity of loose powder. No more eggs are found entire: these are the animals hatched from them, and the shells are what now make the loose powder.

The galls, and such excrescences on vegetables, are always found pierced with holes, out of which the fly issues, which, in its worm state, had been nourished there; and that there might be no resemblance wanting in these creatures to galls, their skins are often found pierced in two or three different places, nay, and flies are seen sometimes issuing out of these, which had lived within them in the worm state. That these are of a certainty animals, and not galls, is evinced, however, beyond doubt and dispute, by raising one of them in an intermediate time between that of its being found full of eggs, and that of its appearing only distended and swelled; because in this interval the animal will be found in the act of laying them, and may be seen doing so.

The young animals hatched from these eggs are for many months seen in the condition of other small insects; but as they become full of eggs, they swell, and, by degrees, lose their true shape: they grow in size as these eggs grow in them, and when full grown and ready to lay, their bellies are smooth and even, and the rings of which they are composed are not to be distinguished: in another state it is easy to distinguish these; they are five in number, and the passage for the eggs is in the last. The animal has six legs, which not having been used of a long time, are found closely applied to its belly; and a little above the first pair there may be seen a small prominence, which is the part by which the creature takes in its nourishment. The cottony bed that lies under these insects on the tree, shews extremely plain the impressions of all the parts of the animal; the legs, rings, &c. are easily distinguishable here.

It is a general law of nature, that insects perish when they have done all that was necessary for the multiplying of their species; that is the case also with this little animal. It lives but a little while after it has laid its eggs, and its dried body makes an excellent covering and defence for them; and what is very remarkable is, that as this insect is now immoveable, and cannot draw itself over its egg, they are not thrown out behind its body, as the eggs of other animals; but as they are laid, are drawn under the belly, and evenly arranged there. The eggs are ten or twelve days before they hatch, and when hatched, the young animals remain quiet under the cover of their mother's carcass for several days.

After some time, when their parts are duly strengthened, they get out and enjoy their liberty: these new-born insects are so extremely small, that it requires a microscope to observe them; but they are in nothing like what their parent was, or what they are to be hereafter; they are very nimble and active, and march backward and forward with prodigious swiftness. There is now nothing singular in their form; they are somewhat flattish, and of an oval figure, and have two horns or antennæ, as well as their six legs, very easily distinguishable. The number of young ones hatched by each parent is very great, often not less than four thousand. The young ones have an easy passage from under the shell made of their parent's body in this, that the hinder extremity of that shell is split, and is not, as are all the other parts, fastened to the branch.

It has been supposed, that the young *gall-insects* eat up their mother's body, and eat holes through it to get out; but this is by no means the case; the opening already mentioned gives them a free passage, and the holes we sometimes see on the backs of these animals are ever made by extraneous animals, small flies, which have in the worm state grown and been nourished within the body of the animal, as they do in the bodies of caterpillars and many other insects; and which, when hatched into the fly state, make themselves these holes for their escape.

It is usually about the beginning of June that the young insects get at liberty from under the body of their parent; they may then be found running very nimbly all over the branches of the tree, but are not distinguishable otherwise than by examining the branches with a microscope. The branches thus covered with these young animals, are in a few days cleared again, and the insects found in form of small scales, covering the leaves, and now large enough to be seen by the naked eye. They are of different colours; some white, some yellow, some greenish, and some reddish: and in this state they are so very flat, and withal so immoveable, that they may naturally be mistaken for the skins quitted by some insects; but on crushing them with one's nail, a yellowish juice is always squeezed out, which shews them to have been real animals; but the greatest proof of it is to be had from observation, for after some time they will be found again very swiftly in motion.

Thus these little animals, after being hatched on the branches, run over them in search of the leaves for nourishment: they do not eat these, however, but suck the juices from their vessels by a fine trunk, and it is only while they are employed in this that they in this state appear immoveable. These trunks are placed a little above the first pair of legs; but we are not to look for them in the young insects, it is only in the full grown ones that they are distinguishable, and in those not without difficulty. In these, however, with attention, one may observe in this part a small hollow, or short fleshy pipe, out of which the insect can at pleasure thrust a fine white trunk, as small as a fine hair, and of half the length of its body.

The more careful gardeners always clear their best fruit-trees from these insects, especially their orange-trees, well knowing that they drain the juices of the tree, and will sometimes even kill it. This is not to be supposed owing to what juices they take in for their nourishment alone, but they occasion the waste of a vast deal besides: under several *peach*-trees, and particularly under distinct parts of them which are loaded with these *gall-insects*, it is common in the middle of May, or between that and the beginning of June, to see the earth as wet as if newly watered, while that all about is dry; a very large quantity of the juices of the tree continually making their way through the holes left by the trunks of these innumerable little animals. At the same time that one finds the young *gall-insects* on the leaves, one finds them also on the young shoots of the *peach*-trees, and the reason is the same, that these parts are more easily pierced by the tender organs of the young animals than the branches and harder parts of the tree. Their backs in this state are not smooth and even, but, examined by the microscope, are found to be wrinkled and channelled in a beautiful and regular manner.

Not only the *gall-insects* of the *peach*, but all the other species, after a certain time, become immoveably fixed to the place where they are, and no longer able to use their legs. Their growth is very slow from the time of their hatching, through the months of July, August, September, and October; at the beginning of November they are found somewhat enlarged in breadth, but they are yet no thicker, and at this time they are all become of the same colour, which is somewhat reddish.

In the beginning of March they begin to swell and be filled with the growing eggs; their backs become a little convex, and, viewed with a microscope, appear covered with little tubercles; and one may, at this time, perceive seven or eight long threads, which run from several parts of their bodies: these fasten themselves to the branch at a distance from the creature, and fix it immoveably in its place. In the beginning of April they become much more convex, and tho' they can no longer walk about, they yet have at this time sufficient motion to shew an animal life. At this time, by very slow motions, they change their skin; and it is after this change that they assume so exactly the figure of galls, and grow so very quickly to their full size. Seven or eight days now make such a change in them, that they are not to be known for the same animal; but it is not till the beginning of May that they ar-

rive at their utmost size. About the 15th of May they are in a condition to lay, and as the eggs are discharged, the belly is pushed closer and closer to the back; and when all are laid, becomes the shell before described, and the young ones are hatched under it, and become full of eggs, and do the same office afterwards to their young.

One great difficulty, however, is to conceive by what means they are fecundated: some have imagined them each to be male and female in the same individual, and hermaphrodites of a very singular kind; for as in snails, worms, and some other insects, which are both male and female in the same individual, there still is the congress of another animal of the same species required for propagation; in these it should seem, on the contrary, that one alone was sufficient. Others imagine them males and females, as other animals, and that they perform these offices during the three or four first days after they are hatched, while they are running on the branches. Had these observers known that the animals were in a condition to move during all the winter months, that is during the greater part of their lives, they would not have been reduced to the improbable conjecture of their performing this office as soon as produced: the truth is, however, that it is not known that they do it at all, these observers never having seen the thing, but only judging it an indispensible necessity; but a close observation will furnish grounds for an opinion of another kind.

In the end of April the branches of the *peach* and other trees covered with these insects, will be found to be greatly frequented by a sort of small flies, beautiful enough to demand attention: their head, breast, body, and legs are all of a deep red; they have only two wings, but those very large, being nearly twice as long as their bodies: these, in the fly's common posture, are crossed on the back, and the upper almost entirely hides the under one; they are less transparent than those of the common flies, and are of a dusky white, bordered with an edge of a fine bright and beautiful red: but what chiefly distinguishes them from all other species is, that they have two long white threads which run from their hinder part, and are of twice the length of their wings; between these there is also a remarkable part, a sort of tail made like a piercer, and of a third or fourth part of the length of these threads. This is like all other stings, thicker at its base than at its point, and is bent a little downwards.

The antennæ of this fly are adorned with long bodies, hairy, and larger at their extremities than at their insertions on the antennæ. It is easy at first sight to conceive, that these are the flies that had been produced of worms fed in the bodies of the *gall insects* of a former year, and that they were now searching an opportunity to deposit their eggs in the bodies of these little creatures, to be hatched into worms there, and thence to come out in flies, as they themselves before had done.

The piercer at their tails made this the more probable, as it seemed to refer them to the ichneumon class; but a closer attention to the whole progress of these insects will give much more room to believe, that these flies are the male *gall-insects*. They are, indeed, very small in proportion to the females, but this will give the judicious naturalist no cause to doubt their being the males of the same species, any more than their having wings and the females not; since the same difference and disproportion is found in beetles and many other insects; the colour of their juices, when crushed, and their smell, are in both exactly the same. And another observation adds greatly to the probability, which is, that many branches of the *peach*-tree are so loaded with the young *gall-insects* that have newly fixed themselves, that one would wonder what must become of them when they swell in bulk, as there could be no room for their growth on the branch on which they already stood so close as to touch one another.

But examining these branches afterwards, at the season when these flies appear, multitudes of these *gall-insects* are found converted into mere shells, out of which something has escaped and gone; and these are so compleat, and seem to have been quitted in so very different a manner from the broken spoils of the female *gall-insects*, that there is all the probability in the world of these flies having been let out of them, which had before lain there in the form of nymphs: several of these, in the very state of nymphs, Mr. Reaumur found in these shells; and the whole remaining question is, whether these were the proper animal, or whether they were owing to the egg of some fly accidentally deposited there, and hatched in the body of the animal. The former, however, seemed on all considerations to be the more probable opinion; for no observation at a proper season will ever shew a living worm in the body of the *gall-insect*: and the manner of the fly's egress is not that of these unnatural births, which are always by a hole made by the fly; but the shell in this case readily opens at a proper season, and lets out the fly, by parting all round at the commissure of the belly and back, which seems too natural for any thing but the very manner destined for the production of the proper species

The flies examined on the branches with a glass will also be found to introduce this seeming piercer always at the same place into the body of the *gall-insect*, and this is that cleft in the hinder part of the body, out of which the young ones when hatched, afterwards find their way. The flies, which lodge their eggs or young worms in the bodies of other insects, if crushed at that season, will be always found to contain such eggs or small worms; and the microscope never fails to discover them in the matter crushed out of flies even smaller than these, but in these no observation ever shews any such. See Tab. of Insects, N° 29

Notwithstanding that the *peach-gall-insect* is the only species in which the male fly has been observed, there is no room to doubt but that the other species all have males of the same kind. The orange *gall-insect* has been observed not universally fecundated, but that there is only a part of the animals that lays eggs; probably the others are those which hatch into the male flies: and the kermes, the noblest and most valuable of all the *gall-insects*, is known often to produce a white winged fly, very like that of the *peach-gall-insect*. And Brennius, who gave some time since a history of the scarlet grain of Poland, the *coccus Polonicus*, a kind of *pro-gall insect*; tho' in the first account he gave into the opinion of both sexes being included in each of these animals, and that each was in itself sufficient for the propagation of its species: yet afterwards, to his very great honour, he added an account of his having discovered the male of this species, which he describes to be a small fly, with a red body and white wings bordered with red; a fly in all respects like the male of the *peach-gall-insect*.

These flies, carefully examined, and pressed gently on their belly, and at the same time observed with a good microscope, will be seen to thrust out of the part which resembles the piercer of the ichneumon race, a fine, slender and soft white thread. Were this in reality the same with the piercers of the ichneumons, this part must have been hard and horny, to be able to enter hard substances; on the contrary, it is ever found soft and fleshy, and is undoubtedly no piercer, but the organ of generation in the male insect.

It is much to be doubted, whether the *gall-insects*, in form of a boat inverted, are not the same species living on different trees: this is certain, that the animal taken from one tree will live and multiply on another; and the distinctions between the species, even so different in their maturity, are often not easy while the animals are young, the boat-fashioned, the orbicular, and the reniform being not distinguishable till the time they acquire the greatest size, and with that size, this their natural figure. The *gall-insects* of the hazel and lime, which are of the half-round kind of the *peach*, and the perfectly orbicular one of the oak, are all instances of this; and all between the time of their being a simple flat body, and their acquiring an orbicular or partly orbicular figure, assume one much like that of the boat-fashioned ones. *Reaumur's* Hist. Inf Tom. IV. p. 1, to 44.

PEANTIDES, the name of a stone to which the antients attributed great virtues for promoting delivery,

These stones were found in Macedonia and other places; and all the description we have of them is, that they resembled water congealed by frost. Probably the antients meant by this name the *stalactitæ*, or stony icicles, which, as they hang from the roofs of caverns, greatly resemble the droppings of water from the eves of houses congealed in frosty weather.

PEARCH, *perca*, in ichthyology. See Perca.

Pearch-*glue*, in mechanics, the name of a kind of glue, of a remarkable strength and purity, the manufacture of which we owe to the Laplanders, from whom Scheffer has described it. They take a number of large *pearches*, and slitting them open, they carefully pick away the flesh with a knife, so as to leave the skin pure. They put a number of these skins into a vessel of warm water, which they expose to the sun, and by that means keep it in a continual moderate heat for several days; when the scales become loose by this maceration, they take out the skins and rub them clean off. The soft and clean skin then remains alone, and feels as soft as a wetted bladder. These clean skins they throw into a small quantity of fresh water, and boil them gently over the fire, stirring the whole together, and toward the end beating it forcibly with little sticks. The skins by this means at length wholly dissolve in the water, and the whole becomes a thick transparent liquor; which, when boiled as long as the thickness of it will permit, without burning, they pour out on a flat stone, and as it cools they cut it into cakes exactly resembling our glue, but that they want the coarse reddish colour it has, and have no disagreeable smell. When they would use this, they dissolve it in more water, exactly as we do our glue. The bows of this people give us a very great proof of the strength of this sort of glue: they are made of two pieces fastened together with it, and tho' put to the most forcible trials, as these people are very strong, and use them in shooting bears, rain-deer, &c. yet the glue part is never known to start. *Scheffer's* Hist. Lapland.

PEAR, *pyrus*, in botany. See the article Pyrus.

All the sorts of *pears* propagated in gardens, are produced by budding, or grafting them upon stocks of their own kind; which are commonly called *free-stocks*, or else upon the quince or whitethorn stocks; but the last are now generally disused, the fruit produced this way being apt to be dry and mealy. The quince-stocks are, however, in great esteem

for the trees designed for dwarfs or for walls; because they do not let the shoots grow so fast and luxuriant. But there are objections against even these, which are of some consequence; for there are many kinds of *pears* which will not do upon them, but will die, or become weak and good for nothing after three or four years; and the hard-breaking *pears* are rendered very unpleasant by being grafted on these stocks, while the buttery or melting ones are meliorated by them. And it is to be added, that no sort of *pear* will thrive upon a quince stock in a poor or gravelly soil.

PEAR-*trees* planted either against walls, or in espaliers, must not be placed nearer to one another than twenty foot. *Pear*-trees commonly produce their blossom-buds first, at the extremity of their last year's shoots; the common way of pruning is very prejudicial, therefore, as it takes off the part which should bear the fruit, and occasions new shoots from the same branch, which will over-fill the tree with wood, the trees should always be carefully looked over in summer, and all the foreright shoots taken off; by which means the fruit will not be over shaded, and the trees will need but little winter-pruning. The several sorts of summer *pears* all ripen best in espaliers, but the winter *pears* require a south-east or south-west, or else an east wall. *Miller's* Gardener's Dict.

It is said that crabs and wild *pears*, such as grow in the wildest and most barren clifts, and on hills, may make the richest, strongest, most pleasant and lasting wines that England yields. See Phil. Transf. N° 477. Sect. 4.

Indian PEAR, a name given by several writers to the fruit of a large tree in the East Indies. The bark of this tree is reddish without and white within, and very smooth; the leaves are small, thick, and of a pale green; the flower consists of three long triangular leaves, which, when shut up, form a sort of triangular pyramid; this is of a very disagreeable smell. The fruit is also of a conic figure, its broad part being joined to the pedicle: this is of a woody texture, and of the thickness of one's finger; it divides itself into several filaments, which run thro' the whole body of the fruit. When the fruit is ripe, its rind or skin is red, very smooth and thin, which is contrary to the common course of nature in the Indian fruits, to which nature has given very thick rinds, in order to make them able to bear the great heats they are exposed to. The inside of this fruit is full of a white, soft, and sweet substance, which is usually scooped out with a spoon, and is of a very pleasant taste: within this fruit there are several smooth, black, kernels, like those of our common *pears*. When this fruit is mellow, the pulpy part of it falls away from the fibres, and they remain hanging to the pedicle for a long time.

Chio PEAR. See CHIO PEAR.

PEARCH, in ichthyology. See PERCA.

PEARLS (*Cycl.*)—Mr. Reaumur was very happy in his conjectures as to the nature, origin, and differences of *pearls*, founded on what he saw in the coarse *pearls* of the *pinna marina*. He very judiciously observes, on that occasion, that often the least valued things are those which most of all explain, even by their imperfections, the manner of formation and the true history of the most perfect.

The *pearls* found in the *pinna marina*, are of two kinds; some being white and glossy, like the common *pearls*, and others brownish, reddish, or blackish. He very well observes, that they are all formed of extravasated juices; which have made their way out of broken vessels, and therefore are the effect of a distempered state of the animal, and are formed in the manner of bezoars in the stomachs of animals, or the stones in their bladders. The inner surface of the shell of the *pinna* is of a silvery white, or of the nature of mother of *pearl*, to a certain depth, after which it is reddish or brownish. These are the two colours also of the two sorts of *pearls*.

The shells of fishes Mr. Reaumur supposes, are formed merely like those of snails, of a viscous matter, secreted from their bodies, which hardens by degrees into a sort of stony texture; and that the *pearls* in this fish owe their colour to their being formed of the extravasated juices of the white or the brown parts of the shells. The juices of these parts are severally intended to form their part, and the bed or plate of shelly matter formed of either, in its proper and natural state, could be only white or brown, as the liquor was coloured; and, consequently, so must be the distempered production of *pearl*. The breaking of the vessels of the inner *pearly* coat both in this and other shells, seems much more frequent than that of those of the browner external part; and it is easy to see, that this may much easier make its way into the hollow of the shell than that from the more outward part; but it is also easy to see that, provided the brown juices of this outer part could be extravasated, and find their way into the hollow of the shell, they could only form *pearls* of their own colour.

In this shell of the *pinna marina*, the white or *pearly* inner part is formed of a vast number of flat plates or beds, laid one upon another; and the brown external part is formed of transverse fibres, not formed into such plates, but running in long striæ. The *pearls* of the two different colours have also this difference in their structure; not but that both the one and the other are composed of concentric beds or plates, but these are much less distinguishable in the brown than in the white ones; and each of them may in these be seen to be made up of filaments exactly as the brown part of the shell, to the extravasated juices of which they owed their origin, and whose texture therefore they could not but emulate. Mem. Acad. Par. 1708.

PEARLS, in commerce, increase in value as the square of their weight: thus, the price of a *pearl* of one carrat being settled at 8 s. to find the price of a *pearl* weighing six carrats: first find the square of six, *viz.* 36; which multiplied by 8 gives 288 shillings, or 14 l. 8 s. the price required. *Jeffries* on Diamonds, p. 64.

PEARL, in ichthyology, a name given by us in the parts about London, to that fish which is called in Cornwall, and other parts of the west of England, *lug-a-leaf*; it is the *rhombus lævis* of the generality of authors; and, according to the new system of Artedi, it is a species of the *pleuronectes*, distinguished by the author by the name of the *smooth bodied pleuronectes*, with the eyes on the left side. See the articles RHOMBUS, PLEURONECTES, and LUG-A-LEAF.

PEARL-*barley* affords to the microscopic observer, a peculiar kind of mite worthy attention, and very different from the common species. The bodies of these have some brown marks upon them, and have not such long hairs as the common mites have; the hinder part of the body also is of a different make. They have eight legs; and before the head there stand two weapons twice as thick as the legs, and of about half their length: these are divided toward the ends with joints like fingers, and these have at their ends a sort of nails formed with sharp and crooked claws; and one of the longest joints is serrated at the edge like a saw. These weapons serve not only as arms and hands to seize hold of things, but they also serve as a defence; for as soon as any danger threatens the creature's head, it erects them both, and makes them meet and fold into one another over the head, as we can join our hands and fingers together in the same erect posture. Phil. Transf. N° 222.

PEARL *colour*, in glass. This beautiful colour is given to glass in the following manner: Put tartar calcined to a whiteness into putrified crystal, while in fusion, at several times, in small quantities, mixing it well every time, till the glass is become of the desired colour; and when it is, work it as quick as can be, for it is a colour that is quickly gone. *Neri's* Art of Glass, p. 103.

PEARL-*fishing*, in the north of Ireland. See an account of it in the Philosophical Transactions, N° 198.

PEASE, *pisa*, in botany. See PISUM.

We have several sorts of *pease* cultivated for use in the gardens about London and elsewhere; and as many people are desirous of having them very early, it is a common practice to raise them on hot beds. The method of doing this is, to sow the *peas* under warm hedges or walls. In the middle of October, when the plants are come up, their stalks are to be kept earthed up, and thus they are to remain till the beginning of January, or even till February, covering them against the severe frosts with *peas*-haulm, or other light covering. In January or February, there must be made a moderate hot-bed; the dung must be laid about two foot thick, and carefully beat down, and covered about six inches deep with light fresh earth; and when the frames have been set on about four days, the plants must be planted in the earth, at about a foot distance, in rows, and placed in each row at about two inches one from another. They must be watered and shaded till they have taken root, and then they must have as much air as may be; and when they begin to fruit, they should be watered more frequently than before, which will occasion their producing a larger quantity of fruit.

The common dwarf *pea* is the sort always used on this occasion, as all the rest ramble too much in their stalks.

The first sort of *pea* to be sown to succeed those on the hot-beds is, the hotspur; of which the gardners reckon three or four sorts, which differ very little from each other; but that called the masters hotspur is usually preferred to the rest. These are to be sown in October, as those intended for the hot-bed, and treated every way in the same manner; but in spring these are subject to be destroyed by slugs and other vermin; the best method of destroying which is, to slake a little lime, and throw over the earth among the plants. For fear of this crop miscarrying by the severity of weather, it is always proper to sow two others after this, at the distance of a fortnight each; and after this there should be no others sowed till the end of January; and after these there should be others at the beginning and end of February. To succeed these, which will supply the table with early *pease*, the Spanish morotto, which is a large *pea*, and a very plentiful bearer, should be sowed in rows on a clear plat of ground; the rows should be two foot and a half distant, and the *pease* dropt at an inch or two asunder: these must be all very carefully covered two inches deep with earth, and the rooks, mice, &c. prevented from getting at them. A fortnight after this another spot should be sowed with this or some other large

large *pea*, and this continued every fortnight till the latter end of May. *Miller*'s Gardner's Dict.

Field-PEASE. The common white *pea* succeeds best in a light land, somewhat rich: the time of sowing them is in the middle of April. Three bushels are the common allowance for an acre; and they kill the weeds a land is subject to, better than any other crop. In Staffordshire they sow the garden rowncivals in fields, and they grow and yield very well, tho' they are left trailing upon the ground without any support of sticks.

The white and rowncival *pea*, are only to be sown with a broad cast, and harrowed in; but the common grey *pea*, which is more frequently sown in fields than either of them, must be sown under furrow, and delights most in a cold wet clay. These are to be sown in February; and the common quantity of seed is two bushels to an acre. The blue *pea* is the best kind for light sandy land, and is to be early sown; all *pease* love land manured with lime or with marle. In Suffolk they plough up their lays in the beginning of March, and turning the turf well, they have a cross-stick set with iron pegs, which they strike down with their feet: these pegs make holes at an even distance; into which they have boys and girls following to put the *pease* singly, till all the land is set. As soon as this crop is cut, they plough the land a-cross, and harrowing it well they plough it again, and sow it about Michaelmas with wheat, and the next year with barley, then with oats; after which the land requires new improvement. *Mortimer*'s Husbandry.

PEASE *bloom-damp*, in natural history. See the article DAMP, *Cycl.* and *Suppl.*

PEAUCIER, in anatomy, a name given by Winslow, in his treatise on the head, and by other of the French writers, to the muscle called by Albinus *latissimus colli*; and by others *detrahens quadratus*, and *quadratus genæ*. Santorini has called the part of this which arises from the cheek, *musculus risorius novus*; and some call the whole *platysma myoides*.

PEBBLES, *calculi*, in natural history, the name of a genus of fossils, distinguished from the flints and homochroa, by their having a variety of colours. These are defined to be stones, composed of a crystalline matter, debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variegations; usually formed by incrustations round a central nucleus, but sometimes the effect of a simple concretion, and veined like the agates, by the disposition, the motion of the fluid they were formed in gave their differently coloured substances.

The variety of *pebbles*, were it of England alone, is so great, that a hasty describer would be apt to make almost as many species as he saw specimens. A careful examination will teach us, however, to distinguish them into a certain number of essentially different species, to which all the rest may be referred, as accidental variations. When we find the same substances and the same colours, or those resulting from a mixture of the same, such as nature frequently makes in a number of stones, we shall easily be able to determine that these are all of the same species, tho' in different appearances; and that whether the matter be disposed in one or two, or in twenty crusts laid regularly round a central nucleus, or thrown without a nucleus into irregular lines, or, finally, blended into a sort of uniform mass.

These are the three states in which we are liable to find every species of *pebble*; for if it have been most naturally and regularly formed by incrustation round a central nucleus, we find that ever the same in the same species, and the crusts not less regular and certain. If the whole have been more hastily formed, and have been the result only of one simple concretion, if that has happened while its different substances were all moist and thin, they have blended together and made a mixed mass of the joint colour of them all; but if they have been something harder when this has happened, and too far concreted to diffuse wholly among one another, they are found thrown together into irregular veins. These are the natural differences of all the *pebbles*; and having regard to these in the several variegations, all the known *pebbles* may be reduced to thirty-four species. *Hill*'s Hist of Foss. p. 512, seq.

These are, 1. A yellowish grey one, with a bluish white crust, very common in the gravel pits about London. 2. A yellow-centered one, with whitish grey and reddish crusts, very common in most of the gravel pits about London. 3. A yellow-centered one, with white, black, brown, and straw-coloured crusts. This is a very beautiful one, and is very common on Hampstead-heath. 4. A dull brown-centered one, with whitish, bluish, and brown crusts. This is a tolerably beautiful stone, and is common about London. This, in a certain state, is a very fine ætites or eagle stone See ÆTITES. 5. A shining brown-centered *pebble*, with white and brown crusts. This is a very elegant stone, and is found plentifully in the gravel-pits about Islington, and more rarely on Hampstead-heath. 6. A small brownish yellow-centered *pebble*, with white, brown, red, and yellow crusts. This is an extremely elegant stone, and is not uncommon in our gravel-pits about London, and would be worth the cutting into toys. 7. A small brown-centered *pebble*, with greyish white, pale brown, brown, and reddish crusts. This is another very beautiful *pebble*, and is common in the gravel-pits on Hampstead-heath. 8. A reddish brown-centered *pebble*, with yellow, red, and bluish white crusts, common about Kensington, and in some other places 9. A brown-centered one, with white, orange-coloured, brown, and dusky yellow crusts. This is an extremely elegant stone, and is common about London. 10. A dull brown centered one, with thick whitish, brownish, and yellowish crusts. This is a very scarce species, and is of the coarsest texture of all the *pebbles*. 11. A bluish white large centered *pebble*, with yellowish-brown, and ash-coloured crusts; very common on Hampstead-heath and about Windsor. 12. An elegant large white-centered one, with flesh-coloured, brown, and bluish-white crusts. This is found principally in Hertfordshire, and is sometimes wrought into toys, and sold in London by the name of an *agate onyx*. 13. An elegant white-centered kind, with red, yellow, and flesh coloured crusts. This is found on Hampstead-heath; and we sometimes meet with it wrought into vases. 14. A greyish-white-centered kind, with very thin and numerous brown, and yellow crusts. This is common in Hertfordshire, and is sometimes found on Hampstead-heath. 15. A greyish-white-centered *pebble*, with brown, yellow, and white crusts; common on Hampstead-heath, and in the gravel-pits about Islington. 16. A very white-centered one, with white, grey, yellow, and flesh-coloured crusts; common in the gravel-pits about London. 17. A brownish-white-centered one, with brownish-white, ferruginous, and yellowish crusts; found about Windsor, and sometimes in Northamptonshire, bedded in the strata of stone. 18. A bluish centered one, with brown and grey crusts; common in Hertfordshire. 19. A grey-centered thick-coated one, with whitish and red crusts. This is a scarce species, but is sometimes found about Paddington, and in some parts of Northamptonshire. 20. A very elegant bluish-white one, with flesh-coloured and bright red crusts; found frequently about London. 21. A bluish-grey one, with brown, yellow, and flesh-coloured crusts; common on Hampstead-heath, and frequently wrought into tops of snuff-boxes. 22. A greenish-blue-centered one, with white, yellow, flesh-coloured, and red crusts; common in many parts of England. 23. A flesh-coloured centered one, with whitish brown and yellowish crusts, and a very thick white external coat. This is a very uncommon species about London, but in Northamptonshire and Leicestershire is found in great abundance 25. A red-centered one, with black, white, and flesh-coloured crusts. This is a very rare species, but is sometimes found on Hampstead-heath. 26. A yellow-centered one, with yellow and greenish white crusts. This is found principally on the shores of Yorkshire. 27. A red-centered one, with purple and pale yellow crusts; found on the shores of Sussex, and sometimes in the gravel-pits about Oxford. 28. A yellow-centered one, with grey and pale-red crusts; found principally on the Yorkshire shores. 29. A pale grey-centered one, with red, purple, bluish, and brown crusts. This is a very scarce species, and found principally in Hertfordshire. 30. A black-centered one, with black and white crusts. This is a very beautiful stone, and is sometimes wrought into seals, &c. under the name of the *onyx*. 31. A yellowish-brown one, with brown and greyish black crusts; very common in Hertfordshire and some other countries, but seldom seen about London. 32. A pale-grey-centered kind, with white and greenish crusts. This is a very elegant stone, and is found on the shores of the Thames, and in the gravel-pits about Islington. 33. A brownish white-centered one, with yellowish brown and black crusts. This is well known among our lapidaries by the name of the *Ægyptian pebble*. And, lastly, 34. A deep green-centered *pebble*, with yellow and pale-crusts. This is sometimes found in the gravel-pits about London, but is not common. *Hill*'s Hist. of Foss. p. 540.

In all the strata of *pebbles* there are constantly found some which are broken, and whose pieces lie very near one another; but as bodies of such hardness could not be broken without some considerable violence, their present situation seems to imply, that they have suffered that great violence in or near the places where they now lie. Beside these, there are others also found which have as plainly had pieces broken off from them, tho' those pieces are no where to be found; whence it seems equally plain, that whatever has been the cause of their fracture, they have been brought broken, as we find them, from some other place, or else that the pieces broken from them must at some time or other have been carried from this place to some other distant one.

Several of these broken *pebbles* have their edges and corners so sharp and even, that it seems evident they never can have been tossed about or removed since the breaking; and others have their sides and corners so rounded, blunted, and worn away, that they seem to have been roughly moved and rolled about among other hard bodies, and that too either with great violence, or for a very long continuance; since such hard bodies could not have been reduced to the condition we now see them in without long friction.

It may be supposed by some, that these stones never were broken,

broken, but have been naturally formed of this shape; but it will be easily seen by any one who accurately surveys their veins or coats that surround the nucleus, like the annual circles of a tree, that they must have been originally entire; and this will be the more plain if they are compared with a stone broken by art. Such *pebbles* as are found in strata, that lie near the surface of the earth, are much more brittle than those which lie in deeper strata.

The more clear and transparent the sand is, which is found among *pebbles*, the more beautiful the *pebbles* are generally observed to be.

The use of these stones, and their disposition in the earth, is a subject of great admiration; and may serve as one of the numerous proofs of an over-ruling Providence in the disposal of all natural bodies. The surface of the earth is composed of vegetable mould, made up of different earth mixed with the putrid remains of animal and vegetable bodies; and is of the proper texture and compages for conducting the moisture to the roots of trees and plants: and under this are laid the sands and *pebbles* which serve as a sort of drain to carry off the redundant moisture deeper into the earth, where it may be ready to supply the place of what is constantly rising in exhalations; and lest the strata of sand should be too thick, it is common to find thin ones of clay between, which serve to put some stop to the descent of the moisture, and keep it from passing off too soon; and lest these thin strata of clay should yield and give way, and by their softness, when wetted, give leave to the particles of sand to blend themselves with, and even force their way through them, there are found in many places thin coats of a poor iron ore placed regularly above and below the clay; and by that means not only strengthening and supporting the clay, but effectually keeping the sand from making its way into it. Phil. Transf. N° 483.

Ridged PEBBLES. It is not uncommon to meet with *pebbles* in our gravel-pits which have one or more ridges, or white lines, standing above the surface of the rest of the stone, in form of a rib or zone, laid on the stone after its formation. This, however, is not the case; but the lime or zone always goes through the whole body of the *pebble*: the matter forming this *ridge* is always harder than the rest of the stone; and it seems probable, that at first it was not extant or elevated, but level with the rest of the surface; but being not so easily worn away by accidents, and when the whole *pebble* came in the way of rubbing among harder bodies, this would be less rubbed away, and consequently would be left more elevated than the rest. We daily see on the sea-shores numbers of stones rounded by the continual rolling and tossing among the waves, and in these the softer parts have given way first and been worn into holes, while the harder have been left prominent. It seems probably to have been the case with these *pebbles* also; but they are not found on the shores, but in our gravel-pits, at a great distance from the sea: and it is evident, that these have had their surfaces thus ground and worn down between the time of their being formed by concretion in the waters of the deluge, and their being deposited where we now find them. This could only happen by means of the hurry and rapid motion of the waters of the deluge, at the time of their running off from the surface of the earth into the ocean or great abyss, at the bottom of it: for, by numerous observations, it is plain, that the force of this water thus returning off from the earth was so great, that in many places it tore up the solid strata, and washed off vast masses from them, tumbling them afterwards along, and rounding and smoothing their surfaces in its passage, and finally leaving them where its force began to abate. This we have instances of in all parts of the world, and that smaller pieces of stone were thus rounded we see in the case of these *pebbles*, the harder parts of which are left standing higher than the rest, and in many other the like instances.

The smoothness of the surfaces of some *pebbles* and flints, which we find with their natural coats or crusts worn off, is another proof of the same thing. These *pebbles*, in this unnaturally naked state, as well as the ribbed and lineated ones, are found in our pits under the strata of earth; and we doubtless find them where they have lain undisturbed ever since the time of their having been deposited there at the going off of the general deluge: and yet they are in exactly the same condition with those which have been tossed about and rounded on the sea shores.

This is a plain indication, that they have been, before their being deposited there, tossed and rolled about in the same manner with the others; and there remains no time at which this should have been done, but that of the going off of the waters of the deluge, when a much larger body of water was evidently in a much greater agitation, and consequently could do in a very little time what we see done on the sea shores in a longer space.

Swallowing of PEBBLES. There are many people of opinion, that the swallowing of *pebbles* is very beneficial to health, in helping the stomach to digest its food, and a *pebble* posset is an old woman's medicine in the colic in many parts of England. They usually order the small white stones to be picked up out of gravel walks for this purpose, and eat them in large quantities in some sort of spoon meat, of which milk is an ingredient.

The thing that has given occasion to this practice seems to have been, that people observe the birds to pick up the gravel, and that they are never well unless they have frequent recourse to this to help their digestion: but this is no similar case at all, for the gizzard or stomach of a bird is made very strong, because the creature hath no teeth to chew its food; and this gizzard is lined with a rough coat, by the help of which and these stones, the food they swallow whole is so ground, as to yield its juices to the nourishment of the animal. But the stomach of man is formed so very differently, that it can never require those assistances to the comminution of food. Many people have, however, accustomed themselves to swallow not only these small white stones, but large *pebbles*, even to the size of a walnut each; and these will often pass safely, and people who have long accustomed themselves to swallow them, boast of receiving no injury from them: we can never know, however, that the death of such persons is not owing to them at last; and as they can do no good, it is best always to avoid them. There is one instance on record, of much mischief done by them; this is in our Philosophical Transactions. Phil. Transf. N° 257, p. 190.

A man of about twenty-seven years of age, and lean habit, had been used for three years before to swallow round white *pebbles*, as a cure for some windy disorders to which he was subject, and they used to pass thro' him easily, and give relief for the time. In one of his fits, at the end of this time, having swallowed his usual number, which was nine, and they not passing thro' him, he swallowed more and more, to the number of two hundred. None of these passed off at the time, nor even in the space of two years and an half; at the end of which time he applied for relief in a miserable way: he could digest no food, but vomited up all he swallowed. On examining his belly, the stones were found lodged, not in the stomach, but almost as low as the os pubis; they might be felt with the hand thro' the integuments, and rattled as if in a bag; if the man was hanged up by the feet to a ladder for a small space of time, they would get up into his stomach again; but upon setting him on the ground they would soon fall into their old place, and that so plainly to the senses, that they might be distinctly heard and counted one by one. If his body was not laxative, he certainly vomited all he eat; if it was, he had a little respite at times; and as he lay in bed he could perceive the stones also higher than their usual place, and give him great disturbance. He was on these occasions always forced to get up, and on standing or kneeling he could perceive them fall down into their old place again, and could count them as they fell. He usually on these occasions could count more than an hundred: at length he became unable to work or move for them, and voided large quantities of blood by stool, after disturbing them by any violent motion. The use of proper medicines relieved him in many of these symptoms, but no means ever made use of was able to carry off one single stone.

PECHEM, in the materia medica, a name given by the modern Greek writers to the root called *behem* by Avisenna and Serapion. Many have been at a loss to know, what this root *pechem* was; but the virtues ascribed to it are the same with those of the *behem* of the Arabians; its description the same, and the division of it into white and red, is also the same as that of the *behem*. Nay, the word *pechem* is only formed of *behem*, by changing the B into a P, which is very common, and the aspirate h into χ, or ch, which is as common.

Myrepsus, who treats of this root, says the same thing that the Arabian Avisenna says of *behem*, namely, that it was the fragments of a woody root much corrugated and wrinkled on the surface, which was owing to its being so moist whilst fresh, that it always shrunk greatly in the drying.

PECHYAGRA, a name given by authors to the gout affecting the elbow.

PECHYS, a name used by some anatomical writers for the elbow.

PECHYTYRBE, an epithet used by some medical writers for the scurvy.

PECORA, *locks*, in the Linnæan System of zoology, a classical term, comprehending a whole order of quadrupeds. The characters of this order are, that the creatures have *dentes incisores*, or *cutting teeth*, in their under-jaw, but none in their upper: they have no *canini*, or *dog-teeth*, and have five molares each way. The paps of this order of animals are situated in their groin, and their feet have hoofs. Of this order are the camel, stag, goat, sheep, and ox. *Linnæi* Syst. Nat. p. 41.

PECTE, in botany, a name given by some of the old Greek writers to the *great comfry*, called also *ossipagina*, from its agglutinating broken bones.

PECTEN (*Cyl*) in natural history, the name of a genus of shell-fish, the characters of which are these: it is a bivalve shell, shutting close in all parts, of a flatted shape, striated in the manner of a comb, and often auriculated, sometimes only semiauriculated, and in some species not auriculated at all. There are also some few species which are elate, not flat as the others.

This genus of shells has had its name *pecten* from the longitudinal striæ with which its surface is covered, which resemble the teeth of a comb. According to the general character of this shell, it will be easy to perceive that it is meant to include the cockles as well as the scallops; these being the *pectens* without ears, and with less flat or elated shells. These are called by all authors by a name which is only a diminutive of *pecten*, *pectunculus*. And tho' the having ears is the common mark of distinction between the *pectens* and the *cockles*, which last usually have none, yet the genera are not distinct, as some have supposed; for there are shells allowed to be *pectens*, or scallops, which have yet no ears, and others universally allowed to be *pectuncles*, or cockles, which have ears. Hence appears the error of Lister, who made these two distinct genera, and gave the ears and the equal convexity of both shells as the great characters of them: these, tho' good marks to distinguish the species by, are by no means unalterable enough to found different genera upon. Hist. Nat: Ecla re. p. 340.

The genus of *pectuncles*, or *cockles*, has been made by all authors a very extensive one, but the reader will find all the supposed species of it very aptly received into the genus of the *cordiformis*, or *heart-shell*, and the *pectens*.

According to this establishment of the genus of the *pecten*, the species are to be enumerated under several distinct heads. Thus, some *pectens* are auriculated on both sides: of these we have the following species; 1. The red *pecten*, called the *ducal mantle* 2. The yellow *ducal mantle pecten*. 3. The coral *pecten*, with beautiful red tubera. 4. The variegated *pecten*, called the St. *James's shell*. 5. The yellow variegated *pecten*, called the St. *Michael's shell*. 6. The gold yellow *pecten* of the Caspian sea. 7. The great reddish *pecten*. 8. The variegated bluish *pecten*. 9. The red deep furrowed *pecten*. 10. The umbrella *pecten*, or, as some call it, the *sun pecten*: this is yellow at the upper part of the shell, and white on the under. 11. The *pecten* which is variegated on the upper part, and white on the under. 12. The yellow high-ribbed *pecten*, with a bordered lip. 13. The *pecten* with both shells equally hollow. 14. The pear-fashioned *pecten*. 15. The beautiful *pecten*, called by Rumphius, *virgineus*. 16. The *amusium*, or smooth polished *pecten* of the same author. 17. The rough *pecten*, variegated with brown spots. Hist. Nat. Eclaire. p. 338.

Of these *pectens*, which are semiauriculated, we have the following species: 1. The black spinose *pecten*: this is all over beset with sharp points. 2. The red spinose *pecten*. 3. The grey spinose *pecten*. 4. The yellow spinose *pecten*. 5. The variegated spinose *pecten*. 6. The smooth white *pecten*.

Of those *pectens* which have no ears at all, we have the following species: 1. The rough *pecten*, called the *file cockle*. 2. The oblong white rough *pecten*. 3. The yellowish ribbed and jagged *pecten*. 4. The variegated *pecten*, jagged at the edge. 5. The thick *pecten*, with blue, yellow, and brown streaks. 6. The smooth variegated *pecten*. 7. The white globose *pecten*, called the *common cockle*.

This shell-fish is one of the spinners of the sea, having a power of spinning or forming threads like the muscle; but they are much shorter and coarser even than those of that fish: so that they can never be wrought into any sort of work, in the manner of the longer and finer threads of the *pinna marina*. The use of these threads which the *pecten* or *scallop* spins, is to fix the creature to any other body that is near, whether it be a stone, a piece of coral, or another shell. All these threads proceed, as in the muscle, from one common trunk; they make their way out of the shell in those *pectens* which have only one ear, a little below that ear; in the others probably they issue out on both sides. It is an evident proof, that the fish has a power of fixing itself at pleasure to any solid body by means of these threads, that after storms the *scallops* are often found tossed upon rocks, where there were none the day before; and yet these are fixed by their threads, as well as those which had remained ever so long in their place. They form their threads in the very same manner with the muscle, only their organ which serves for spinning is shorter, and has a wider hollow, whence the threads are necessarily thicker and shorter. See MYTULUS.

PECTINATION, *combing of the head*. Frequent *pectination* is recommended by many physicians to women, and men who wear their hair, as an exercise; and at the same time, a kind of friction.

PECTORAL (*Cycl*).—PECTORALIS *internus*, in anatomy, a name given by Riolan and others to a muscle of the breast, now generally known by the name of the *triangularis sterni*; called by the older writers, *sextus thoracis*.

PECTORALIS *major*, a large, thick, and fleshy muscle, covering the breast from the stomach, where it is very broad, to the axilla, where it contracts in its passage to the arm. It is naturally divided into two portions, one superior and small, and the other inferior and large; the first may properly be called the *clavicular portion*, the other the *thoracic*.

The *clavicular portion* is fixed by a fleshy insertion in almost half the clavicle next the sternum, ending under the insertion of the sterno-mastoidæus; from thence it runs obliquely down towards the axilla, contracting by small degrees, and finally ending in a flat tendon or tendinous band. The *thoracic* portion is broad, and in some measure radiated. It is fixed by its anterior circumference in the lateral part of the outside of the sternum, in the outside of the cartilages, and in a small part of the bones of all the true ribs, and of the first and sometimes the second false rib; all these insertions are like so many digitations. The insertions in the sternum, end by a great number of very short tendons, which run towards the middle of the bone, meeting and decussating those from the same muscle on the other side.

This muscle, together with the deltoides, sends off an aponeurosis, which joining that of the biceps, is spread over the muscles of the arm: it partly covers the pectoralis minor, and serratus major; and by its broad tendon covers transversely the brachial channel, and the tendon of the biceps lodged there. Lastly, it forms the anterior border of the hollow of the axilla, as the posterior is formed by the latissimus dorsi. *Winslow*'s Anat. p. 180.

PECTORALIS *minor*, a muscle called also *triangularis*. It is small and fleshy, something of a triangular shape, and is situated at the superior, lateral, and anterior part of the thorax. By its basis it is inserted into the external labium of the upper edge of the second, third, fourth and fifth true ribs, near their union with the cartilages, by the same number of digitations, or separate fleshy portions, between the intervals of the ribs; and for that reason it has been called the *serratus minor anticus*. From hence these portions run up more or less obliquely toward the shoulder, and form a fleshy belly, which contracts as it passes before the two first ribs; and then becoming a short, flat, and broad tendon, is inserted in the upper part of the apophysis coracoides of the scapula, reaching all the way to the point of that process. This muscle is covered by the *pectoralis major*, and adheres very closely to the external intercostal muscles. The digitations commonly taken notice of cover and hide several others, by which the number of fibres and thickness of this muscle is increased. Its tendon unites a little at the apex of the coracoide apophysis, with the insertion of the coraco-brachialis, and with that of one portion of the biceps.

PECTOREL, in our old writers, armour for the breast, a breast-plate or *petral*, for a horse. It is mentioned Stat. 14. Car. II. c. 3.

The word *pectorel* comes from the Latin *pectus*, a breast.

PECTORIS *ossa*, in fishes. The bones of the breast and belly are best sought after in the cetaceous and spinose kinds. In the spinose kinds they are these: the clavicles, the sternum, the scapulæ, or bones, to which the *pinnæ pectorales* are affixed at their basis, the bones at the roots of the *pinnæ ventrales*. The number, situation, and figure of these differ greatly in the several kinds of fish, and make very essential characters. *Artedi* Ichthyol.

PECUARII, among the Romans, those who farmed the public pastures, in order to let them again to advantage. *Pitisc.* Lex. Ant. in voc.

PECULATOR, one who is guilty of the crime called *peculate*. See PECULATE, *Cycl.*

PEDARIAN, in antiquity, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the house.

The origin of the word Dr. Middleton thinks owing to this, that tho' the magistrates of Rome had a right to a place and vote in the senate, as well during their office as after it, and before they were put upon the roll by the censors, yet they had not probably a right to speak or debate there on any question, at least in the earlier times of the republic. For this seems to have been the original distinction between them and the antient senators, as it is plainly intimated in the formule of the consular edict, sent abroad to summon the senate, which was addressed to all senators, and those who had a right to vote in the [a] senate. From which distinction, these last, who had only a right to vote, were called by way of ridicule, *pedarian*; because they signified their votes by their feet, not their tongues, and upon every division of the house, went over to the side of those whose opinion they approved [b]. It was in allusion to this old custom, which seems, however, to have been wholly dropt in the later ages of the republic, that the mute part of the senate continued still to be called by the name of *pedarians*, as we learn from Cicero [c], who in giving an account to Atticus, of a certain debate and decree of the senate upon it, says, that it was made with the eager and general concurrence of the *pedarians*, tho' against the authority of all the consulars [d]. [[a] *Festus* in voc. senatores, *A. Gell.* l. 3. 18. [b] Vid. *A. Gell.* ibid. *Fest.* in pedarius. [c] Ad *Attic.* 1. 19. [d] *Middlet.* of Rom. sen. p 86. seq.]

PEDATURA, in Roman antiquity, was used for a space or proportion of a certain number of feet set out. *Pitisc.* Lex. Antiq. in voc.

The word occurs frequently in writers about military affairs: thus in Hyginus de Castrametatione we meet with, *meminerimus itaque ad computationem cohortis equitatæ milliariæ pedaturam ad milletrecentis sexaginta dari debere*; which is to be thus explained: the *pedatura*, or space allowed for a cohors equitata, or provincial cohort, consisting of both horse and foot, (see COHORS *equitata*) could not be the same as the *pedatura* of an uniform body of infantry, of the same number, but must exceed

ceed it by 360 feet: for the proportion of the room of one horseman to one foot soldier he assigns as two and an half to one. Vid. Phil. Transact. N°. 482. sect. 3.

PEDETICHE, in natural history, a name given by some of the Greek writers to the chamois goat, the creature whose skin affords us the chamoy leather.

The antient Greeks called this creature *ixaros*, and from thence came the word *isarus* and *yssaros* or *ysardos*. The Latin authors of antiquity call this *dama*, but authors have since applied the word *dama* to the *cervus platyceros*, or broad-horned stag.

Aristotle has called this last animal *prox*, and his translators have rendered the word *dama*; but they are in this to be understood as meaning the *dama* of their own times, not that of the antients, or this *pedetiche*, or chamois goat.

PEDICULARIS (*Cycl.*)—PEDICULARIS, *lousewort*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of a personated form, and divided into two lips; the upper one hooded, the lower divided into three segments: the pistil arises from the cup, and is fixed in manner of a nail to the hinder part of the flower. This afterwards ripens into a capsule, divided into two cells, and containing oblong, flatted, and marginated seeds. See Tab. 1. of Botany, Class 3.

The species of *pedicularis* enumerated by Mr. Tournefort, are these: 1. The common meadow yellow *pedicularis*, called yellow rattle and cockscomb. 2. The taller meadow yellow *pedicularis*, with horny flower cups. 3. The Alpine *pedicularis*, with pale yellow spiked flowers. 4. The serrated clammy-leaved meadow yellow *pedicularis*. 5. The umbellated Spanish *pedicularis*. 6. The narrow-leaved mountain *pedicularis*. 7. The spiked Italian *pedicularis*, with changeable coloured flowers. 8. The sea *pedicularis*, with long serrated leaves. 9. The narrow-leaved annual Alpine yellow *pedicularis*. 10. The least spring annual purple *pedicularis*, called by some purple eye-bright. 11. The least annual white flowered spring *pedicularis*. 12. The short blunt-leaved English red *pedicularis*, called also red eye-bright. 13. The blackish red-flowered Alpine *pedicularis*, with teucrium leaves. 14. The speedwell-leaved Pyrenean *pedicularis*. 15. The tall germander-leaved Portugal *pedicularis*. 16. The late flowering purple *pedicularis*. 17. The late flowering yellow *pedicularis*. 18. The narrow flax-leaved *pedicularis*. 19. The Portuguese grassy-leaved meadow *pedicularis*. 20. The Spanish marsh *pedicularis*, with glass wort leaves. 21. The yellow Alpine *pedicularis*. 22. The great fern-leaved Alpine *pedicularis*. 23. The small fern-leaved Alpine *pedicularis*. 24. The spleen-wort leaved Alpine *pedicularis*. 25. The purple Alpine *pedicularis*, with asphodel roots. 26. The broader leaved, asphodel-rooted, Alpine, red *pedicularis*. 27. The common meadow purple *pedicularis*. 28. The white-flowered meadow *pedicularis*. 29. The taller red meadow *pedicularis*. 30. The taller white meadow *pedicularis*. *Tourn.* Inst. p. 172.

A decoction of *pedicularis* is esteemed good against hæmorrhages and fluxes of all kinds. *Demery*, Dict. des drogues.

PEDICULUS, the *louse*, in the history of insects. See LOUSE.

PEDICULUS *marinus*, a name given by some to the Molucca crab. *Ray's* Ichthyogr. p. 3. See SQUILLA.

PEDILUVIUM. The uses of warm bathing in general, and of the *pediluvium* in particular, are so little understood, that they are often preposterously used, and sometimes as injudiciously abstained from. Med. Ess. abr. Vol. I. p. 244.

In the Medical Essays of Edinburgh, we find an ingenious author's opinion of the warm *pediluvium*, notwithstanding that of Borelli, Boerhaave, and Hoffman, to the contrary, to be: that the legs becoming warmer than before, the blood in them is warmed; this blood rarifying, distends the vessels; and in circulating imparts a great degree of warmth to the rest of the mass: and as there is a portion of it constantly passing through the legs, and acquiring new heat there, which heat is, in the course of circulation, communicated to the rest of the blood; the whole mass rarifying, occupies a larger space, and of consequence circulates with greater force. The volume of the blood being thus increased, every vessel is distended, and every part of the body feels the effects of it; the distant parts a little later than those first heated. The benefit obtained by a warm *pediluvium* is generally attributed to its making a derivation into the parts immersed, and a revulsion from those affected, because they are relieved; but the cure is performed by the direct contrary method of operating, *viz.* by a greater force of circulation through the parts affected, removing what was stagnant, or moving too sluggishly there. Warm bathing is of no service where there is an irresoluble obstruction, tho' by its taking off from a spasm in general, it may seem to give a moment's ease; nor does it draw from the distant parts, but often hurts by pushing against matter that will not yield with a stronger impetus of circulation than the stretched and diseased vessels can bear: so that where there is any suspicion of scirrhus, warm bathing of any sort should never be used. On the other hand, where obstructions are not of long standing, and the impacted matter is not obstinate, warm baths may be of great use to resolve them quickly. In recent colds, with slight humoral peripneumonies, they are frequently an immediate cure. This they effect by increasing the force of the circulation, opening the skin, and driving freely through the lungs that lentor which stagnated or moved slowly in them. As thus conducing to the resolution of obstructions, they may be considered as short and safe fevers; and in using them we imitate nature, which by a fever often carries off an obstructing cause of a chronical ailment. Borelli, Boerhaave, and Hoffman are all of opinion, that the warm *pediluvium* acts by deriving a larger quantity of blood into the parts immersed. But arguments must give way to facts: the experiment related in the Medical Essays seems to prove to a demonstration, that the warm *pediluvium* acts by rarifying the blood. Vid Med. Ess. abr. Vol. I. p. 245. seq.

A warm *pediluvium*, when rightly tempered, may be used as a safe cordial, by which circulation can be roused, or a gentle fever raised; with this advantage over the cordials and sudorifics, that the effect of them may be taken off at pleasure. Med. Ess Edinb. abr. Vol. I. p. 237.

Pediluvia are sometimes used in the small pox; but Dr. Stevenson thinks their frequently tumultuous operations render that suspected, and at best of very doubtful effect; and he therefore prefers Mons. Martin of Lausanne's method of bathing the skin, not only of the legs, but of the whole body, with a soft cloth dipped in warm water, every four hours, till the eruption; by which means the pustules may become universally higher, and consequently more safe. Med. Ess. abr. ib. p. 248.

PEDO, in natural history, a name given by some writers to the *tipula*, or father long-legs; called also by others, *Gruina*, or the crane-fly.

PEDRO *de Porco*, a sort of bezoar, called by the Portuguese *pedro de vassar*, and found in the gall bladders of the wild boars in the Indies. It is usually of the size of a filbert, and of an irregularly oval shape; it is generally of a pale greenish colour, and of a very smooth surface.

This sort of bezoar is extremely valued; the Dutch East India fleets are seldom able to bring home more than five or six of the stones, and they are purchased at three or four hundred livres each, by the opulent burghers, either for presents to the great, or else to be handed down to their posterity in their families; so great is their opinion of their virtues.

The Indians call this species of bezoar, *masticha de scho*, and have as high a veneration for its virtues as the Dutch. The Inhabitants of Malacca also esteem it greatly, not as an antidote against poison, but as a remedy for the mordixi; a disease to which they are subject, and which is as fatal as the plague with us. It is also esteemed a very valuable medicine in the small pox. The method of using it is to suspend it in wine or water, till it has given it an agreeable bitterness; and this is to be drank every morning, and as often beside as the nature of the disorder may require. The common method of keeping it is in a gold box, bored full of holes, and having a gold chain fastened to it: by this means they can dip it into liquors as they please, without taking it out of the box; and by that means prevent the mischiefs it might get by handling. *Bont.* Med. Ind.

PEDUNCLE, among botanists, expresses that little stalk wh ch grows from the trunk or branches of a plant, and supports the parts of fructification, the flower and the fruit, or either: when this is produced from the stalk, it is called *caulinus*; when from the alæ of the leaves, *alaris*; when it terminates the plant or its branches, *terminalis*.

PEDUNCULARIA, in botany, a name by which some authors have called the *staphisagria*, or stavesacre; a plant whose seeds are used to kill vermine. *Ger.* Emac. Ind. 2.

PEE, in mining, is used for the place where two veins meet and cross one another, thus ┼. *Houghton's* compl. Miner, in explan. of the terms

PEGANELÆON, a word used by the antients to express oil, in which the leaves and flowers of rue had been infused and insolated.

PEGANERON, a name given by some old authors to a plaister in which rue was a principal ingredient, from *peganon*, the Greek name of rue.

PEGANON, or PEGANUM, a name used by some authors for the *ruta sylvestris*, or wild rue; called *harmala*, or *harmel*, in the shops. *Ger.* Emac. Ind. 2. See HARMALA.

PEGEMUS, one of the many names by which the Chemists have called mercury.

PEGMA, among the Romans, a wooden machine, used in theatrical entertainments, which was raised and let down by secret engines, whence it was said to grow. *Pitisc.* Lex. Ant in voc.

PEGOMANTIA, Πηγομαντεία, in antiq ity, a species of divination, which was performed with fountain water. See the article HYDROMANTIA.

PEGORELLA, in ichthyography, a name by which some have called a fish of the trutaceous kind, caught in the Mediterranean, and more usually called *callarias*. *Bellonius* de Pisc. See the article CALLARIAS.

PELADA, a kind of alopecia, or distempered state of the body, occasioning the shedding of the hair, arising from a venereal cause. *Castel.* Lex. Med.

PELÆAS, Πελειάς, in zoology, the name by which the antients called that species of pigeon now known by the name of the *livia* and *sassarollo*; a grey pigeon, of a very small size, and with some variegations of purple and green. *Ray's* Ornithol. p. 136. See LIVIA.

PELAGIA, (*Cycl.*) in natural hiftory, a name by which Pliny, and other of the antient naturalifts, have ufually called the *purpura*. See PURPURA.

PELAMYS, in zoology, a name by which the antients expreffed the young brood of the *thynnus*, or tunny fifh, at a certain age and fize; but later writers have appropriated the word for the name of a diftinct fpecies of fifh, of the fame genus, called by others *farda*; and by fome by the two names joined into one, *pelamys-farda*.

It is a fea-fifh, of the fhape of the tunny; but of a fmooth fkin, and free from fcales every where, except about the gill-fins. Its teeth are large, long, and crooked. Thefe are the only external marks by which it is to be known from the young brood of the tunny; but when brought to the table, it is eafily diftinguifhed by the hardnefs of its flefh. *Ray*'s ichthyography, p. 179.

PELAMYS *vera*, a name given by Rondeletius, and fome other authors, to the fifh more diftinctly known by the name of *amia*. *Willughby*'s Hift. Pifc. p. 180. See AMIA.

PELANI, Πελανοι, among the Athenians, a kind of cakes ufed in their libations. *Pott.* T. I. p. 214.

PELATÆ, Πελαται, in antiquity, a particular kind of fervants among the Athenians.

The *pelatæ* were free-born citizens, who, by reafon of their indigence, were forced to ferve for wages. They had no fuffrage in public affairs, as not being mafters of an eftate proper to qualify them for giving their votes; but this reftriction was not perpetual. They were otherwife called *thetes*, and continued in the condition of fervants only during their own pleafure and neceffities; for they had power either to change their mafters, or (if they became able to fubfift themfelves) wholly to releafe themfelves from fervitude. *Pott.* Arch. Græc. T. I. p. 57.

PELECANUS, a name given by fome authors to the *platea*, or fpoon-bill; a bird very different from the pelican, being of the ftork, or heron kind. *Aldrovand.* de Avib.

PELECINUS, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the papilionaceous kind, and from its cup arifes a piftil, which finally becomes a flat, bicapfular and bivalve fruit, containing feveral flat feeds, ufually approaching to a kidney-like fhape.

There is only one known fpecies of this genus, which is the plant called by fome the fmooth-podded *fecuridaca*, and by others the radiated *lunaria*. *Tourn.* Inft. p. 417.

PELICAN, (*Cycl.*) in the Linnæan fyftem of zoology, makes a diftinct genus of birds of the order of the *anferes*, or goofe kind; the characteriftic of which is to have a beak of a depreffed form, with a hooked point, and furnifhed with a large bag or purfe beneath. *Linnæi* fyftem. Nat. p. 46.

PELLA, in zoology, a name by which many have called the common grey heron. See the articles ARDEA and HERON.

PELLACK, the name of a young fpout-whale, often found in Zetland; where they run into creeks, and fo entangle themfelves among the rocks, that they are caft on fhore, or eafily taken. Phil. Tranf. N°. 473, fect. 8.

PELLAGE, in our old writers, a cuftom or duty paid for fkins or leather. Rot. Parl. 11 *Hen.* IV. *Blount.*

PELLITORY *of Spain*, in the materia medica. See the article PYRETHRUM.

PELLITORY *of the wall.* See PARIETARIA.

PELOPIA, Πελοπεια, in antiquity, a feftival celebrated by the Eleans, in honour of Pelops, for whom that nation had more veneration than for any other hero. For the ceremonies of this folemnity, fee *Pott.* Archæol. Græc. l. 2. c. 20. T. I. p. 429.

PELORIA, Πελωρια, in antiquity, a feftival not unlike the Roman faturnalia, celebrated by the Theffalonians. *Pott.* Archæol. Græc l. 2. c. 20. T. I. p. 425.

PELORIDES, in natural hiftory, a name given by fome to a peculiar fpecies of chama. Bellonius, who firft ufed the word, never gives it alone as the name of the fhell, but only ufes it as an epithet derived from *peloro*, the name of the place where a particular fpecies of chama was very frequent.

PELT-*wool*, wool ftripped of the fkin or *pelt* of a dead fheep. Stat. 8 Hen. VI. c. 22. *Blount, Cowel.*

PELTASTES, Πελτασης, among the antients, one who ufed the buckler called *pelta*. See PELTA, *Cycl*

PELTATED-*leaf*, PELTATUM *folium*, among botanifts. See the article LEAF.

PELVIS (*Cycl.*)—The *pelvis* is the third and loweft part of the trunk, confifting chiefly of two large pieces, called *offa innominata*; which being united anteriorly by a cartilaginous fymphyfis, and pofteriorly to the two fides of the os facrum, reprefent a kind of bafin. When confidered feparately, they are of no determinate figure; being of different breadths in different parts, and unequally convex on the outfide, and unequally concave within. Each bone is but one piece in adults, but in children each confifts of three pieces, joined together by a cartilage; which afterwards perfectly offifies, leaving commonly no veftige of the firft divifion. Anatomifts confider it, however, even in adults, as made up of three portions; and diftinguifh them by different names, as if they were three different bones. Of thefe three bones the largeft is fuperior and pofterior, and is called *os ilium*. The fecond inferior called *os ifchium*: and the third and fmalleft anterior called *os pubis*. Without entering on the particular defcription of thefe, (which, fee under their proper heads) it is to be obferved, that there are in the entire bone feveral common parts, or parts which belong to more portions of it than one, *viz.* a deep cartilaginous cotyloide cavity, called in Latin *acetabulum*: this is formed by all the three portions. A large opening, called the *foramen ovale*, formed by the *os ifchium* and *os pubis*. A large pofterior notch or finus, called the *ifchiatic* notch, and formed by the *os ifchium* and *os ilium*. An oblique eminence, or protuberance, above the *acetabulum*, toward the *foramen ovale*, made by the *os ilium* and *os pubis*: and to thefe may be added, a ridge on the infide the *pelvis*, which divides the wide upper part from the bottom, to which alone the antients gave the name *pelvis* *Winflow*'s Anatomy, p. 69.

PELUS *armena*, in the materia medica, a name given by fome of the old writers to the drug that we at prefent call *bole armoniac*. This was the original name, and the term *bolus armena* is not to be found, but in the later writers.

PEMPHINGODES, an epithet beftowed by Hippocrates on fevers by flatulencies and inflations, in which the patient feels a kind of wind paffing along under the fkin, and the phyfician may perceive it in the fame places rifing againft the preffure of his finger, called by fome an inflative fever.

PEMPTÆUS, a word ufed by medical writers, as the name of an ague, the fits of which return always on the fifth day.

PENDANT-*gardens*. See PENSILES *horti*.

PENDULOUS *roots*, among botanifts, fuch as are fixed to the ends of fibres, whence they feem to hang. See ROOT.

PENDULUM (*Cycl.*)—Mr. Poleni feems to think, that if a long *pendulum* were made to fwing in the place of the meridian, and another of equal length in a plane perpendicular to the meridian, fome difference might be found in their vibrations from the centrifugal force arifing from the earth's rotation about its axis. See Phil. Tranf. N°. 468. fect. I.

Pendulum clocks refting againft the fame rail, have been found to influence each other's motions. See the Phil. Tranf. N°. 453, fect. 5 and 6, where Mr. Ellicot has given a very curious and exact account of this phænomenon.

PENELOPE, in zoology, the name ufed by authors for the bird commonly known in England by the name of the *wigeon*; called alfo in fome places the *whewer*; and by the Germans the *fchmey*. The head and upper part of the neck in this bird are of a reddifh hue, variegated with black fpots; but toward the beak the colour is paler, and blended with fome white and yellow. The upper part of the breaft and the fides are of a deep reddifh hue, and variegated with tranfverfe ftreaks of black, and the back is brown; the head is proportionably fmaller than that of the wild duck. It feeds on weeds and fmall fhell-fifh. *Ray*'s Ornithol. p. 288.

PENETRALE, among the Romans, properly denoted the chapel confecrated to the *penates*, or houfehold gods. *Pitifc.* Lex. Ant. in voc. See PENATES, *Cycl*

PENGUIN, in zoology, a name given by failors of different nations to two different fpecies of water-fowl, both web-footed, and both wanting the hinder toe.

The *penguin* of the Englifh is the bird more commonly known by the name of the *goifugel*.

It grows to the fize of a common tame-goofe, and is black on its back, or upper part, and white on the belly. Its wings are very fmall, and by no means fit for flying. Its beak is fomewhat broad and long, compreffed on the fides and back, and has toward the extremity feveral furrows, feven or eight on the upper fide, and about ten on the under; and the lower chap fwells into a protuberance downward. Its head has two white lines reaching from the beak to the eyes. It tail is very fhort, and it has no hinder toe.

The *penguin* of the Dutch is the *anfer magellanicus* of Clufius. *Ray*'s Ornithol. p. 242. See the article DUCK.

PENICILLI *marini*, in natural hiftory, a fort of marine tubuli, or cafes of fea-worms, making a diftinct genus of thofe fhells. They are defined to be fhelly tubes, very flender, and terminating in the fhape of a painter's pencil; many of them in their native ftate adhering to ftones, &c. on the fea-fhores, by means of a foft and lax fubftance. Some of thefe are white and pellucid, others yellowifh or brown; and the more common fort are about a finger's length, and about the thicknefs of a wheaten ftraw; and fome are of a fort of funnel-like fhape, and have their mouths furrounded by a fort of hairs, or filaments. Thefe are called by fome *probofcipleEtani*, others are called *cadi*, and others *entalia*. *Klein*, de Tubul. Marin. p. I.

PENIS (*Cycl.*)—Bleeding in the vena dorfalis of the *penis* is ufually found to furpafs all remedies whatever in abating inflammatory diforders of this member. This large vein, which runs along the back or upper fide of the *penis*, being generally pretty much diftended and confpicuous in an inflammation of this part, may be opened about the middle, and kept bleeding till the member becomes flaccid, and a fufficient quantity of blood be difcharged proportionably to the urgency of the cafe; which done, a comprefs muft be applied, and kept on by bandage. There muft, however, be great caution in this operation not to injure the arteries or nerves which enter the *penis* near this vein, as alfo not to make the bandage too

ſtrict, by which the inflammation and ſymptoms may become worſe than before. *Heiſter's* Surgery, p. 284.

PENIS *primus muſculus*, in anatomy, a name given by Veſalius and others, to a muſcle of the *penis* now generally known by the name of *accelerator*.

PENITENTS, in the church of Rome. See POENITENTES.

PENNANT, in a ſhip, a ſhort rope made faſt at one end to the head of the maſt, or to the yard-arm, with a block at the other end, and a ſhiver to receive ſome rope into. All the yard-arms, except the miſen, have *pennants*.

PENNATED-*leaf*, in botany. See LEAF.

PENNEVISCH, in zoology, a name given by ſome to the moſt common ſpecies of the fiſh called *bagre*, caught in the Eaſt and Weſt Indies. *Ray's* Ichthyol. Append. p. 4. See the article BAGRE.

PENNY (*Cycl.*) — PENNY-*earth*, in agriculture, a term uſed by the farmers for a hard loamy, or ſandy earth, with a very large quantity of ſea ſhells intermixed in it; ſome of which being round and flat, and in ſome meaſure reſembling pieces of money, have occaſioned the earth's being called by this name. It is an earth not eaſily dug, but is uſually undermined with pick-axes, and then falls in large lumps; which, with the froſts, break to pieces, and leave the ſhells looſe. It is prepared by breaking and mixing well with water, and then makes very deſirable floors. The Jerſey combers combpots are alſo made of it, and the ſides and roofs of ovens are plaiſtered with it; and being rightly managed, it combines into a floor almoſt as ſtrong as plaiſter of Paris. *Moreton's* Northampt. p. 66.

PENNYROYAL, *pulegium*, in botany, &c. See PULEGIUM. The ſeveral ſorts of *pennyroyal* all propagate themſelves very faſt by their trailing branches, which take root at every joint; ſo that no more is required in their culture and propagation than to cut off and plant out theſe rooted branches: they ſhould be planted at a foot diſtance every way, that they may have room to grow. The beſt ſeaſon for this is in September, that the plants may be rooted before winter. They love a moiſt ſoil, and generally grow very faſt. *Miller's* Gardener's Dict.

PENSILES-*horti*, in antiquity, gardens raiſed on arches by the kings of Babylon. Q. Curtius makes them equal in height to the walls of the city, *viz.* fifty feet. Trees of a very large ſize grew and flouriſhed here. *Hofm.* Lex. in voc. *Q. Curt.* l. 5. c. 1.

PENTACEROS, in natural hiſtory, a name given by Linkius, and ſome other authors, to a kind of *ſtella marina*, or *ſea ſtar-fiſh*, compoſed of five principal rays, with ſeveral tranſverſe hairy or downy proceſſes.

PENTACTINODOS, in natural hiſtory, a name given by ſome authors to thoſe ſpecies of ſtar-fiſh which are compoſed of a body divided into five rays.

PENTADACTYLON, *five fingers*, in botany, a name given by ſome authors to the *ricinus* or *palma chriſti*, from the figure of its leaf. *Ger.* Emac. Ind. 2.

PENTADACTYLOS *piſcis*, *the five fingered fiſh*, in zoology, the name of a fiſh common in all the ſeas about the Eaſt Indies, and called by the Dutch there *viif vinger viſch*.

It has this name from five black ſtreaks which it has on each ſide, reſembling the prints of five fingers. It grows to about a foot and a half long, and its head is ſmall in proportion to its body. Its ſnout is long, and its fins large, and reaching almoſt to its tail. Its general colour is very bright and elegant, a yellow with an admixture of purple and of a ſilvery gloſs. It has no ſcales, and is a dry but not ill-taſted fiſh. *Ray's* Ichthyogr. Append. p. 6.

PENTADACTYLOS-ASTER, in natural hiſtory, a name given by Linkius, and ſome other authors, to a ſpecies of *ſtar-fiſh*, compoſed of a ſmall body, and five principal rays, which have each ſeveral proceſſes coming from them, covered with down.

PENTAEDROSTYLA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek πέντε five, ἕδρα ſides, and στῦλος a column.

The bodies of this genus are ſpars, in form of pentangular columns, terminated by pentangular pyramids at one end, and irregularly affixed at the other to ſome ſolid body.

Of this genus there are three known ſpecies: 1. One with a very long pyramid. This is found in the mines on Mendip-hills. 2. One with a thick column, and a very ſhort and large pyramid. This is found in the Hartz foreſt in Germany and in Cumberland. And 3. One with a broad depreſſed pyramid. This is found, ſo far as is yet known, only in the mines at Rammelſberg in the Hartz foreſt in Germany. *Hill's* Hiſt. of Foſſ. p. 220.

PENTAGON-ASTER, in natural hiſtory, a name given by Linkius, and other authors, to a kind of *ſtella marina*, or *ſtar-fiſh*, compoſed of five rays, with a number of tranſverſe proceſſes iſſuing from them, covered with a hairyneſs.

It is one of the general claſſes of the *ſtellæ crinitæ*, ſo called from this hairyneſs.

PENTAGONOTHECA, in botany, the name given by Vaillant to the plant called by Linnæus, Plumier, Houſton, and others, *piſonia*. It has this laſt name from Piſo, the great botaniſt, and the other from the figure of its ſeed-veſſel, which is of a ſort of pentangular figure, but contains only one cell. *Vaillant* Act. Germ. See PISONIA.

PENTANDRIA, in botany, a claſs of plants which have hermaphrodite flowers, with five ſtamina or male parts in each. See Tab. 1. of Botany, Claſs 1.

The word is formed of the Greek πέντε five, and ἀνὴρ male. Of this claſs of plants are the primroſe, willow-herb, bindweed, &c.

PENTANGLE, in geometry, a figure with five angles.

PENTAPHARMACUM, a medicine conſiſting of five ingredients: it has alſo been uſed in the ſame ſenſe to aliments. Adrian the emperor was, as we are informed, particularly fond of a diſh of five ingredients, called by this name. The ingredients were the udder of a ſow, ham, peacock, brawn, and a ſort of paſte.

PENTAPHYLLOIDES, in botany, the name of a genus of plants, the characters of which are theſe: The flower and fruit are the ſame with thoſe of the common cinque-foils, but the leaves do not grow as in that at the tops of the ſtalks, but arranged along them, as in the other plants.

The ſpecies of *pentaphylloides*, enumerated by authors, are theſe: 1. The erect *pentaphylloides*, called by authors the *ſtrawberry-cinque-foil*. 2. The procumbent *pentaphylloides*, called by authors the *creeping ſtrawberry-cinque-foil*. 3. The ſilvery *pentaphylloides*, with alated leaves, called by authors, *argentina*, *potentilla*, *ſilver-weed*, and *wild tanſy*. 4. The upright ſhrubby *pentaphylloides*. 5. The red-flowered marſh *pentaphylloides*. 6. The red-flowered marſh *pentaphylloides*, with thicker and hairy leaves. *Tourn.* Inſt. p. 298.

PENTAPLEURUM, a name given by ſome botanical writers to the common ſmall plantain, uſually called *ribwort* and *plantago quinquenervia*, from its leaves always having juſt five ribs running along them.

PENTAPTEROPHYLLUM, in botany, a name by which Dillenius has called the *myriophyllum* of other authors, charactered under that name in the genera plantarum of Linnæus, p. 459. See MYRIOPHYLLUM.

PENTAUREA, a name given by ſome fabulous authors to a ſtone ſaid to have been firſt found by Apollonius Tyaneus, and to poſſeſs the virtues of all the other ſtones, and to attract them all to it, as the magnet does iron.

PENTECONTARCHA, among the antients, the captain, or commander of a galley, called *penteconteros*. *Pitiſc.* Lex. Ant. in voc. See PENTECONTEROS, *Cycl.*

PENTELICUM-*marmor*, in the works of the antients, a name given to a very beautiful and gloſſy ſpecies of white marble, of which many of the columns and ſtatues of larger ſize of the antients were made: the Parian marble, from certain cracks and fiſſures in the ſtrata, ſeldom affording blocks of more than five foot in length.

PENTEXOCHE, a name given by authors to a ſpecies of echinites, reſembling the ripe fruit of a medlar, and thence called alſo *meſpileus lapis*.

PENTHORUM, in botany, the name of a genus of plants, the characters of which are theſe: The cup is very ſmall and permanent; it is compoſed of one leaf divided into five ſegments at the edges. There is no flower, the ſtamina are ten ſetaceous filaments of double the length of the cup. Theſe are permanent, the antheræ are roundiſh and fall off very quickly. The germen of the piſtil is divided into five parts, and terminates in five ſtyles, which are conic, erect, and of the length of the ſtamina. The ſtigmata are obtuſe; the fruit is a capſule divided into five parts, and containing five cells. The ſeeds are numerous, ſmall, and compreſſed. *Linnæi* Gen Plant. p. 204.

PENTODRYON, in botany, a name given firſt by the Greek writers, and after that by the Romans, to a kind of *ſtrychnum* or *nightſhade*, which cauſed madneſs in thoſe who eat of it. This was called by others *manicum ſtrychnum*, and by ſome ſimply *manicum*.

PENTOPHTHALMOS, in zoology, the name of an Eaſt Indian fiſh, approaching to the European *liparis* or *butterfiſh*, but larger, and called by the Dutch there *viifoog*. It has theſe names from five round ſpots in the tail-fin, reſembling five eyes. It is of a yellowiſh colour, and is covered with a ſmooth ſkin, having no ſcales. Its body is thick; its head ſmall; its beak long. It has two red fins, and its tail is bluiſh. It is an inhabitant of the freſh waters, and is a very well-taſted fiſh. *Ray's* Ichthyogr. Append. p. 6.

PEPIN-*cyder*. See CYDER.

PEPITA, in the materia medica, a name given by ſome authors to the *faba ſancti Ignatii*, or *St. Ignatius's bean*. *Dale* Pharm p. 328.

PEPLION, or PEPLOS, names given by the antients to medicines which they uſed as briſk cathartics to purge off the bile and other humors.

PEPLIUM, in botany, a name given by the antient Greek writers to a ſhrub which had pinnated leaves and papilionaceous flowers. It is tranſlated by many *ſena*; but this does not appear certainly to be right: the ſeveral ſpecies of *colutea* agree as well with this deſcription as the *ſena*, and they have indeed been called *ſena* by many; probably it was one of theſe.

PEPLUS,

PEPLUS, Πεπλος, among the antients, a kind of garment worn by women. *Pitisc.* in voc.

The *peplus* was a long robe that reached to the feet, without any sleeves, and so exceeding fine that the shape of the body could easily be discovered through it. Hist. l'Acad. Inscr. vol. 3. p. 401.

The *peplus* of Minerva is very famous among antient mythologists. The Athenians used a great deal of ceremony in the making the *peplus*, and dressing the statue of this goddess with it. See *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 421.

PEPLUS, in botany, a name given by some authors to the smaller round-leaved species of *tithymal*, or *spurge*, as they call the narrow-leaved ones *esula*. See the article TITHYMALUS.

PEPO, the *pompion*, or *pumpkin*, the name of a genus of plants allied to the melon and cucumber kinds. The characters of the genus are these: The flowers consist of one leaf each, shaped like a bell, wide open at the mouth, and divided into several segments at the end. Of these flowers some are male or steril, having no embryo; others are female or fruitful, having an embryo, which ripens into a large fruit, with sometimes a smooth, sometimes a rough bark. The figure is sometimes oval, sometimes round, and the bark often very hard, tuberous, and hollow: it is divided into three cells within, and contains flat seeds surrounded with a sort of ring, and fixed to a spongy placenta.

The species of *pompion*, enumerated by Mr. Tournefort, are these: 1. The great long-fruited *pompion*. 2. The great round-fruited *pompion*. 3. The orange-fruited *pompion*. 4. The ball *pompion*, or *ball gourd*, called by authors *cucurbitula pilæ palmariæ figura*. 5 The small round fruited-*pompion*, called the *small rough-fruited yellow gourd*. 6. The round-fruited variegated *pompion*. 7. The *pompion* with a variegated fruit of a turbinated form. 8. The turbinated white *pompion*. 9. The turbinated yellow *pompion*. 10. The least turbinated *pompion*. 11 The pear-fashioned *pompion*. 12. The oval yellow *pompion*. 13. The rough oval yellow *pompion*. 14. The variegated yellowish oval *pompion*. *Tourn.* Inst. p. 105.

We generally esteem the *pompion* but an unwholsome food, but there is another use in it worth enquiring into. The world heard much of the fame of a secret medicine prepared by Petrus de Castro, chief physician to the duke of Mantua, for the cure of pleurisies. When the secret of this was discovered and published in the Acta Leipsiensia, it appeared to be no more than the rinds of the oblong Italian *pompions*, pared clean from the pulp, and boiled many hours together in old oil of olives.

PEPPER (*Cycl.*) — *Ciapa* PEPPER, *pimienta de Ciapa*, a name given by the Spaniards to a sort of spice which they discovered in Ciapa, a province of Guatimala in New Spain, and of which they were at first very fond, both in food and medicine.

In medicine it is a very good cephalic and stomachic. It is recommended very strongly also by some of the Spanish writers, as a cure for the epilepsy and the gutta serena, but those who have tried it in these cases do not confirm such accounts.

The descriptions we have of it are, that it has the taste of cloves, pepper, cinnamon, and ginger, all blended together; and Redi is of opinion, that it is no other than our *pimenta*, or *Jamaica pepper*. *Redi's* Esperien.

PEPPER-*mushroom*, in botany, a name given by Dr. Lister to a new species of fungus, discovered by him in the woods of Yorkshire, whose juice is acrid and hot as pepper. This is somewhat larger than the common esculent mushroom, but of the same shape with that, having a round head and open gills underneath. The head is very fleshy, and the pedicle also is solid, not hollow, as in most other of the larger fungoses: any part of this *mushroom* being cut or broken, it bleeds very freely a white milky juice, like that of the tithymals. This juice tastes like pepper, only that it is much hotter. It is not viscous or clammy to the touch, and the air does not much discolour it; nor does it render the blade of the knife, with which it is cut, black, as most other vegetable juices do. When let out of the plant it very soon concretes into a firm and dry mass, making a sort of cake; and when thus dried into a solid substance, it retains its white colour and pungent taste. It is very remarkable, that this *mushroom*, tho' so hot to our tongues as not to be endured, yet is so well suited to the palates and nature of certain insects, that they can not only feed on it, but live comfortably in the midst of it. The yellow naked snail feeds greedily on the plant while growing, and the stalks of it at such times as the juice is sharpest of all, that is, while it is growing to the full size, are full of the maggots or worms hatched from the eggs of flies, deposited there for a nidus and food for them in that state. The juice has a great affinity with euphorbium, and may be brought into medicinal use, perhaps, to very good purpose.

John Bauhine describes a *mushroom* much resembling this, but smaller and less fleshy; and the Prussians and Polanders have a sort of great *mushroom*, which they call *groozdishys*, which agrees with this in many particulars; but it is larger and thicker. Phil. Trans. N° 89. See the article GROOZDISHYS.

PEPPER-*tree* of Jamaica. See PIMIENTA.

PEPPER-*water*, a liquor prepared by the curious for examination by the microscope, as always affording a great number of small animals.

The method of preparing it is this, put common black *pepper* grossly powdered, into an open vessel so as to cover the bottom of it half an inch thick, and put to it rain or river water, till it covers it an inch, shake or stir the whole well together at the first mixing, but never disturb it afterwards: let the vessel be exposed to the air uncovered; and in a few days there will be seen a pellicle or thin skin swimming on the surface of the liquor, looking of several colours.

This is a congeries of multitudes of small animals; and being examined by the microscope, will be seen all in moti n: the animals, at first sight, are so small as not to be distinguishable, unless to the greatest magnifiers; but they grow daily till they arrive at their full size. Their numbers are also continually increasing, till the whole surface of the liquor is full of them, to a considerable depth. When disturbed they will sometimes all dart down to the bottom, but they soon after come up to the surface again. The skin appears soonest in warm weather, and the animals grow the quickest; but in the severest cold it will succeed, unless the water freezes. *Baker's* Microscope, p. 71.

About the quantity of a pin's head of this scum, taken up on the nib of a new pen, or the tip of a hair pencil, is to be laid on a plate of cle r glass; and if applied first to the third magnifier, then to the second, and, finally, to the first, will shew the different animalcules it contains, of several kinds and shapes as well as sizes Phil. Trans. N° 284.

The animalcules found in this liquor, are principally of six kinds: 1. The largest kind of all is in length about the diameter of a hair, and of scarce a fourth part of that measure in breadth: they are very thin and transparent, but their back is darker than their belly: they turn about very frequently and nimbly in the water; their sides are fringed with a great number of minute feet, which are seen principally at the two ends; and at one end there are also some bristles longer than the feet, which make a sort of tail. They are very nimble, and walk as well as swim, and will climb up a hair if put in among them.

2. There is a smaller sort, whose length is about a third of a hair's breadth; but their tail is five or six times as long as their body. This they either carry strait, or in a spiral form; and at the other end they thrust out a sort of bearded tongue: these make a constant current of water toward them.

3. There is a smaller sort than these, which are sometimes seen of an oval figure, and sometimes long and flat like a flounder: these also have feet which are plainly seen when the water is evaporating.

A fourth kind appear like slender worms, fifty times as long as broad: their thicknesss is not above the hundredth part of a hair's breadth; and they move with equal ease either forward or backward. There are a fifth sort extremely minute and round; and a sixth kind which are longer than these, but not larger; and probably there may be yet many kinds not discovered. These small animals are easily destroyed; a little dissolved salt or sugar, or spirit of vitriol, or even spittle will kill them; and in the drying away of the waters many of them burst. Phil. Trans. N° 203

PERÆQUATORES, among the Romans, assessors appointed to regulate the *census* according to every man's circumstances, by easing those that were overcharged, and raising the taxation if too low. *Pitisc.* in voc.

PERANEMA, in zoology, the name of a Brasilian fish, of the size of the pearch, being ten or eleven fingers in length, and about three fingers broad in the broadest part.

Its mouth is large and round, and has no teeth, but several very rough and sharp prominences. Its eyes are large, and it has one long fin running down the back, which is supported by rigid and prickly rays. Its tail is not forked; its whole body is a silvery white, with a faint blush of red. Its scales are extremely small, and of a triangular figure, and its belly is very white. It is a sea fish, and is wholesome and well-tasted. *Marggrave's* Hist. Brasil. *Willughby's* Hist Pisc. p. 339.

PERANITES, the name of a stone mentioned with many idle stories of its origin, by the writers of the middle ages.

It seems originally to have been only a corruption of the word *peartides*, a name by which the antients seem to have called our *stalactites* or *dropstone*

PERCA, the *pearch*, in the Linnæan system of zoology, the name of a genus of fishes of the order of the acanthopterygii. The characters of these are, that the membrane of the gills has seven bones, and the back has one or two fins. Of this genus are the *perca*, *lucioperca*, *lupus*, &c. *Linnæi* Systema Naturæ. p. 53.

In the Artedian system of ichthyology, the characters of the *pearch* are these: It is of the acanthopterygious kind. The branchiostege membrane on each side, contains seven bones. The scales are very hard and rough, or armed with a sort of little

little hooks at the ends; and the upper lamina of the coverings of the gills is ſerrated at the edges. There are ſometimes two fins on the back, ſometimes only one.

Of the former ſort, or thoſe which have two fins on the back, the ſpecies are, 1. The *pearch* with ſix tranſverſe black lines, and with the fins of the belly red. This is our common *pearch*. 2. The pale ſpotted *pearch*, with two teeth in the jaws, on each ſide, larger than the others. This is the *lucioperca* or *barſe*. 3. The *pearch* with eight or nine black tranverſe lines on each ſide. This is the *aſper piſciculus* of authors.

Of thoſe *pearch* which have only one fin on the back, the following are the ſpecies: 1. The *pearch* with one back-fin, and a cavernous head. This is the *cernua* of authors. 2. The *pearch* with one back-fin, with black longitudinal lines on each ſide. This is the fiſh called by the Germans *ſchraitſer*. 3. The *pearch* with ſeven tranſverſe black lines on each ſide, and with red and blue marks on the head and belly. This is the *perca minima auctorum*. 4. The *pearch* with thirteen rays in the back-fin, and forty in the *pinna ani*. This is the *labrax* of authors, by ſome called the *lupus marinus*; and by others *ſpigola*; we call it a *baſſe*. *Artedi* Gen. Piſc. p. 38.

The name *perca* is of Greek origin, and is derived from the word πέρκος, which ſignifies variegated with black or duſky ſpots; a character common to moſt of the ſpecies of this fiſh.

The common *pearch* affords good ſport for the angler. The beſt time for their biting is, when the ſpring is over, and before the heats of ſummer come on. At this time they are very greedy, and the angler, with good management, may take at one ſtanding all that are in the hole, be they ever ſo many.

The proper baits are a minow or young frog; but the worm called the *brand ing*, well ſcowered, is alſo excellent at all times of the year. When the *pearch* bites, he ſhould always have a great deal of time allowed him to ſwallow the bait. The *pearch* will bite all day long, if the weather be cloudy; but the beſt time is from eight to ten in the morning, and from three till ſix in the afternoon. The *pearch* is very abſtemious in winter, and will ſeldom bite in this ſeaſon of the year; if he does at all, it is in the middle of the day; at which time indeed all fiſh bite beſt at that ſeaſon.

If the bait be a minow, which is the bait that affords moſt diverſion to the angler, it muſt be faſtened to the hook alive, by putting the hook thro' the upper lip or the back-fin; it muſt be kept at about midwater, and the float muſt be a quill and a cork, that the minow alone may not be able to ſink it.

The line muſt be of ſilk, and ſtrong; and the hook armed with a ſmall and fine wire, that if a pike ſhould take the bait, as is not unfrequently the caſe, he may be taken. The way to carry the minows or ſmall gudgeons alive for baits, is this: A tin pot is to be provided with holes in the lid, and filled with water, and the fiſh being put in this, the water is to be changed once in a quarter of an hour by the holes, without taking off the lid at any time, except when the bait is to be taken out.

A ſmall caſting-net made for theſe little fiſh ſhould be taken out with the *pearch* tackle, and one or two caſts of this will take baits enough for the day, without any farther trouble. When the bait is a frog, the hook is to be faſtened to the upper part of the leg. The beſt place for the fiſhing for *pearch* is, in the turn of the water near ſome gravelly ſcour. A place of this kind being pitched upon, it ſhould be baited over night with lobworms choped to pieces; and in the morning on going to it, the depth is to be regularly plumbed, and then the hook is to be baited with the worm or other bait; and as it drags along, the *pearch* will ſoon ſeize upon it.

Perca *amboinenſis*, in zoology, the name of a freſh water fiſh, ſomewhat reſembling our pearch, but differing in that it is of a brown colour, and has ſeveral blue lines under its ſnout, and ſome blueneſs in the adjoining fins, but its back and belly fins are green. It is caught in the lakes and rivers of freſh water, at Amboina, and is a very delicately taſted fiſh. *Ray*'s Ichthyogr. Append. p. 1.

Perca *aurata*, the *gilded pearch*, a fiſh of the ſhape of the pearch, but remarkable for a gold colour about its gills: it is common in our rivers, and is called in Engliſh a *ruffe*; its more common name among authors is *cernua*. *Geſner* de Piſc. p. 825. See Cernua.

Perca *marina*, the *ſea pearch*, in zoology, the name of a ſea fiſh, much reſembling the common freſh water pearch in ſhape, ſize, and colours, but ſomething thinner in proportion to its length, and more variegated.

Its back is variegated with ſix or ſeven blackiſh tranſverſe lines, like thoſe of the pearch, and the intermediate ſpace is of a ſomewhat reddiſh hue, eſpecially toward the head. Its whole head, and part of its belly, are very elegantly variegated with red and blue ſtreaks. Its back fin is of a pale yellow, with ſeveral reddiſh yellow ſpots, and is very long, and has its anterior rays terminated in ſpines. Its mouth is extremely wide, and almoſt always gapes open; its teeth are ſharp, and its eyes very large. It is very common in the Mediterranean, and is a well-taſted fiſh. *Rondelet.* de Piſc. p. 170. *Geſner* de Piſc. p. 819.

PERCOLATION (*Cycl.*)—Many have attempted the condenſing of wines by *percolation*, or ſeparating from them that ſuperfluous moiſture or water, which dilutes them below the true ſtandard of vinous liquors, in order to make them richer and fitter for keeping; but it does not appear that ſuch attempts have as yet ſucceeded. See *Stahl*, de concentr. vin.

PERCUNOS, the name of an antient Pruſſian idol. See the article Potrimpos.

PERCUSSION (*Cycl.*)—If an elaſtic body ſtrike a larger elaſtic body at reſt, the ſmaller body will always rebound, and move in a contrary direction to what it did at firſt, and alſo give the larger body a greater quantity of motion than what was originally in the ſmaller body. And this quantity of motion communicated, may be greater than the original motion, in any ratio leſs than that of 2 to 1. For ſuppoſing the ſmall body and its velocity, to be denoted by unity, and the larger body at reſt by x, the velocity of x after the ſhock will be $\frac{2}{1+x}$, and its quantity of motion will be $\frac{2x}{1+x}$. But tho' the proportion of $2x$ to $1+x$ increaſes when x increaſes, yet its limit will be the proportion of 2 to 1; which is the limit to which the motion of x may approach indefinitely near.

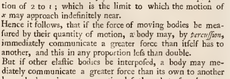
Hence it follows, that if the force of moving bodies be meaſured by their quantity of motion, a body may, by *percuſſion*, immediately communicate a greater force than itſelf has to another, and this in any proportion leſs than double.

But if other elaſtic bodies be interpoſed, a body may mediately communicate a greater force than its own to another larger body x, in any proportion leſs than that of $x\sqrt{x}$ to 1. Thus if $x = 1000000$, the body 1 with the velocity 1, may, by the means of intermediate bodies, give it the force 999000000; and the ſum of the abſolute forces of all theſe bodies taken together, ariſing from the *percuſſion*, may exceed the force of the firſt or unity, in any ratio leſs than $2x\sqrt{x}$ to 1, or 2000000000 to 1, altho' the relative force in all caſes remains as at firſt $= 1$.

Theſe are paradoxes which cannot be urged againſt thoſe who maintain the forces of bodies to be meaſured by their maſſes and the ſquares of their velocities.

It is alſo to be obſerved, that thoſe who meaſure force by the quantity of motion, muſt deny that there is any force loſt by the impreſſions made on ſoft bodies, or by the bending of elaſtic bodies: for if any were loſt from ſuch cauſes, the ſum of the quantities of motion of bodies moving the ſame way, could not remain the ſame before, during, and after the ſhock, which is an univerſal rule admitted by the Newtonians. But they admit that a ſpring bent between two bodies may, by unbending itſelf, generate motion in theſe bodies. Hence it follows, that according to this doctrine, tho' a ſpring may give motion to bodies, it cannot, by a contrary action, take it away; which ſeems no ſmall paradox.

If a body A move towards the body C, at reſt, and an intermediate body B of a mean magnitude be placed at reſt between them, ſo that A firſt impels B, and then B impels C, a greater motion will be given to C than if A had ſtruck it directly. And if B be a mean proportional between A



and C, the velocity communicated to C will be the greateſt that can be. *Huygens*, de mot. Corp. ex Percuſſ. Prop. 12.

If more bodies be interpoſed between A and C, the motion of C will be greater; and it will be the greateſt when the bodies interpoſed conſtitute a ſeries of mean proportionals between A and C. Ibid. Prop. 13.

If there be a ſeries of an hundred bodies in the proportion of 1, 2, 4, 8, 16, &c. and the motion begins by the greateſt body, the velocity communicated to the ſmalleſt will be to that with which the greateſt moved nearly as 2,338,500,000,000 to 1. And if the motion begins by the leaſt body, the quantity of motion will be increaſed on the whole nearly as 1 to 4,677,000,000,000. *Huyg.* ib.

But it is to be obſerved, that there is a miſtake in the impreſſion of Huygens's book, as to the firſt number, which is there printed 14,760,000,000, inſtead of 2,338, &c. ſo that the velocity thus given to the ſmalleſt body is 150 times greater than what the printed copy of Huygens aſſigns. *Bernoulli*, Diſc. ſur le Mouv. Oper. Tom. 3. p. 34. and *S. Graveſande*, Pref. ad Huygen Oper. Poſth. Tom. 2. Amſt. 1728.

This ſtupendous augmentation of the quantity of motion, is a remarkable inſtance of the falſity of the Cartesian principle,

ciple, that the same quantity of motion is always preserved in the world.

Some have thought this augmentation no small difficulty against those who maintain the moving force or power of action in bodies, to be proportional to their quantities of motion. This difficulty does not press the Leibnitians; for it is to be observed, that notwithstanding the prodigious increase of motion here assigned, yet there is no increment of the *vis viva* of this system of bodies. See the articles FORCE and VIS *viva*

A learned author has urged, that if the force of bodies were in proportion to their quantities of motion, the increase in the motion here mentioned might be employed to restore the motion of the first body, and hence make a perpetual motion. But it is answered, that as the motion of the last is increased in the same direction with the first, the motion of all the rest will be in the contrary direction, and equal to that of the last diminished by unity: hence the sum of the motions in the same direction, remains as it did, equal to that of the first and smallest body, which we suppose unity. See *Maclaurin's* Demonstrat. des Loix du choc des Corps, p. 21. Paris, 1724. and *S. Gravesand*, rem. sur la possibilité du mouvement perpetuel in Journ. Liter.

It is to be observed, that there is a limit which the velocity communicated to the last body never amounts to, (supposing the first and last bodies, and the velocity of the first before the stroke, to be given) but to which it approaches continually, while the number of such bodies interposed between the first and last is always increased. And this limit is to the velocity of the first body before the stroke, in the subduplicate ratio of the first body to the last.

Mr. Huygens has not mentioned this limit, but the curious may see the determination of it in Mr. Maclaurin's fluxions, art. 514. In the case mentioned by Huygens, this limit will be a number expressed by fourteen figures, for its logarithm is 14.9004850.

PERDIX, the *partridge*, a bird well known and esteemed at table, of which naturalists enumerate five species. 1. The common *partridge*. 2. The Brasilian *partridge*, called *iambu*, of a dusky yellow colour, spotted with brown: of this there are two species, a larger and a smaller. See the article IAMBU. 3. The *perdix damascena* of Aldrovand, which resembles our *partridge*, but its feet are yellow and its beak longer. 4. The red-legged *partridge*, common in France and Italy, and called there *cotumo*. See COTUMO. And, 5. The Græcian *partridge*, which is twice as large as ours, and not seeming to differ from the *cotumo* in any thing but size: they are all very finely tasted birds, but none are so delicate as the *cotumo*. *Ray's* ornithology, p. 119.

PERDIX *alba*, the white *partridge*, a name given by many to the *lagopus*, a rough-footed bird of the gallinaceous kind, common on the snowy mountains, and by some called the *rabolane*. See the article LAGOPUS.

PERDIX *marina*, the *sea-partridge*, a name given by some authors to the foal-fish, from the firmness and delicacy of its flesh. *Bellon.* de Aquat. Vol. I. p. 34.

PERDIX, in conchyliology, a name given by authors to a genus of shells, supposed to resemble the partridge in the shades and disposition of the colours.

The partridge-shell is of the *dolium*, or *concha globosa* class, and is striated and spotted in a peculiarly elegant and regular manner. See DOLIUM.

PERDONIUM, a term, invented by Paracelsus, to express wine medicated with herbs.

PEREGRINATORES, in botany, a name for such students in that science as have taken long journies, and visited the remotest regions, in search of plants. *Linnæi* Fund. Bot. p. 1.

PERETERION, a name given by chirurgical writers to the perforating part of the trepan.

PERFECT, *perfecti*, in church history, a designation which the followers of Valentinus assumed to themselves. *Hoffm.* Lex. invoc.

PERFOLIATA, the same with bupleurum, or hare's ear; a plant recommended by authors as a vulnerary of the first class. It is applied externally to contusions, fresh wounds, and luxated joints. There are many who esteem it a remedy even for the king's evil, and its virtues in the cure of navel-ruptures have long been famous: but all this wants proof. See HARE'S *ear*.

PERFOLIATE-*leaf*, among botanists. See LEAF.

PERFORATA, in botany, a name given by some authors to the *hypericum*, or St. John's wort, from the small holes seen all over its leaves, if held up to the light. *Ger.* Emac. Ind. 2.

PERFORATUS (*Cycl.*)—PERFORATUS *brachii*, in anatomy, a name given by Placentini to a muscle of the arm, now generally known by the name of the *coraco-brachialis*. It has been by many disputed not to be a distinct muscle. Vesalius calls it only *pars interioris principii cubitum flectentium primi carnosa*, esteeming it only a part of that muscle. Many of the writers who followed Vesalius have given it also the name of *pars* and *portio*, not esteeming it a distinct muscle: and Casserius, who wrote after Placentini, calls it only *portio carnosa*, and censures that author for thinking it a distinct muscle, and calling it *perforatus*.

PERIAMMA, a word used by some medical writers to express an amulet.

PERIANTHIUM, in botany, expresses that sort of cup which consists of several leaves, or else of one leaf divided into several segments, and surrounds the lower part of the flower. See the article CALYX.

PERIAGOGE, Περιαγωγή, in rhetoric, the same with peribole. See the next article.

PERIBOLE, a word used very frequently by Hippocrates, and in different places, in very different senses. Sometimes it signifies a translation of the humors from one part to another; sometimes only the dress or garments of a patient. In the first of these senses, the word is frequently used to express a translation of the morbific matter from the center to the surface, in the termination of a disease, by the breaking out of pustules all over the body.

PERIBOLE, Περιβολή, in rhetoric, is used where many things are accumulated into one period; which might have been divided into several. We have an instance in Cicero's defence of Flaccus: *Quod si esset aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen existimavi, Judices, Decium Lælium, optimi viri filium, optimâ ipsum spe præditum, summæ dignitatis, eam susceptu rum accusationem, quæ sceleratorum potius civium odio, & furori, quam ipsius virtuti, atque institutæ adolescentiæ, conveniret.*

Now this long period might very well have been divided into the three following: 1. *Quod si esset aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen existimavi, judices, Decium Lælium, eam susceptu rum accusationem.* 2. *Est enim is optimi viri filius, optimâ ipse spe præditus, summæ dignitatis.* 3. *Accusatio vero hæc sceleratorum potius odio et furori, quam ipsius virtuti atque institutæ adolescentiæ, conveniret.* *Vossii* Rhet. l. 6. p. 439. seq. See PUNCTUATION, *Cycl.*

PERICALAMITIS, in the materia medica of the antients, a name given by some to the *adarce*.

We find the word *pericalamitis* in a description recorded in Galen, and it has generally been understood to mean *styrax*, that being called *calamita*: but the *adarce* is the thing signified by the name, which expresses its manner of formation, it being always found concreted about the stalks of reeds that grow on the edges of waters. *Galen* l. 1. See ADARCE.

PERICARDIUM (*Cycl.*)—We read of a *pericardium* of a monstrous size, out of which above three pounds of coagulated blood and serum were taken. See Medic. Ess. Edinb. Vol. V. art. 56.

PERICARPIUM, among botanists, a covering or case for the seeds of plants: it is the germen of the pistil enlarged. There are no less than nine species of *paricarpia*: 1. A capsule. 2. A conceptaculum. 3. A pod. 4. A legume. 5. A nut. 6. A drupe. 7. An apple. 8. A berry. 9. A strobilus. See CAPSULE, CONCEPTACULUM, &c.

PERICHAREIA, a word used by the antients to express a sudden surprize of joy, such as has been frequently known to occasion death.

PERICHRISIS, a word used by the antients for a liniment, principally of the oleaginous or spirituous kinds, and as thin and fluid as oil.

PERICLASIS, a word used by the antients for a fracture of a limb, attended with a large wound, by which the broken ends of the bone, or part of it, are laid bare.

PERICLYMENUM, *wood-bind* or *honey-suckle*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is tubular, and divided into several segments at the edges; the cup finally becomes a roundish juicy fruit or berry, containing a compressed seed of a rounded shape.

The species of *periclymenum*, enumerated by Mr. Tournefort, are these: 1. The ever green Virginian long flowering *periclymenum*: and, 2. The yellow flowered Indian *periclymenum*. *Tourn.* Inst. p. 608.

PERICNEMIA, a word used by some medical writers for the parts about the calf of the leg.

PERIDONIUS *lapis*, in natural history, a name given by some of the writers of the middle ages to the *pyrites*, which they call also *perithe*.

PERIDROMIDES, Περιδρομίδες, in antiquity. See XYSTI.

PERIDROMOS, a word used by the old Greek writers to express the extreme edge of the hairs of the head, when hanging down in their natural form.

PERIESTECOS, in medicine, an epithet for diseases, signs, and symptoms, which are salutary, and prognosticate the future better health of the patient.

PERIGRAPHE, a word usually understood to express a careless or inaccurate delineation of any thing: but in Vesalius it is used to express the white lines or impressions that appear in the musculus rectus of the abdomen.

PERILEUCOS, in the natural history of the antients, a name given to an agate; but not of a distinct species, but only a particular appearance of the lead-coloured agate, more usually known among them by the name of *phassachates*. See the article PHASSACHATES.

PERINENEUCOS, an epithet given to a peculiar sort of irregular pulse common in hectic patients, in which the artery beats more strongly in some parts than in others. See the article EPINENEUCOS.

PERIOSTEUM *(Cycl.)*—The bones of the human body in their natural ftate, are for the moft part covered exteriorly by a membrane, called by the general name *periofteum*. This is extended over the cartilages and ligaments alfo, as well as the bones; but when it covers the cartilages, it is called *perichondrium*, when the ligaments, *peridefmium*.

The *periofteum* in general is a fine ftrong membrane, or membranous expanfion, not equally thick in all its parts, more or lefs tranfparent, of a very clofe texture, not eafily yielding, extremely fenfible, and compofed of feveral planes of fibres differently difpofed, and mixed with a great number of fine veffels and nervous filaments.

This membrane does not immediately furround thofe portions of bones which are covered by cartilages, nor thofe in which ligaments or tendons are inferted; neither does it cover thofe portions of cartilages which are expofed to friction, as in the moveable articulations, channels, &c. and laftly, it does not cover thofe portions of the teeth which lie out of the fockets and gums. The innermoft plane of the fibrous texture of the *periofteum*, or that which immediately adheres to the furface of the bones, is fixed thereto by an infinite number of fmall fibrous extremities, brought from all the planes, and which enter the pores of the bones. Thefe extremities are accompanied by capillary veffels and nervous filaments, which having run for fome fpace between the different planes of the *periofteum*, perforate the innermoft at the orifices of the pores of the bones. The *periofteum* is of different thickneffes, but this difference of thicknefs does not appear near fo much on the outer furface, as on the inner; which is marked in many places with impreffions, owing to the fulci, depreffions, lines, and inequalities on the furface of the bones.

Some anatomifts have been of an opinion, that this membrane was not only united to, but clofely braced round the bones; and that therefore it might fet bounds to their growth. It is probable they had only examined a few bones on this occafion, for had they confidered thofe which have concave furfaces, depreffions, and inequalities, they would there have found only a fimple adhefion of the *periofteum*, without any tenfion. In places where it is only fixed to the bone by the filaments of its innermoft plane, it is eafily pulled off from the bones; but where the fibres of the other planes likewife penetrate the bones, efpecially when thefe planes are very numerous, and where the infertions of tendons and ligaments mingle with thefe fibres, the feparation is much more difficult.

The *periofteum* in general ferves to fupport that admirable texture of an infinity of capillary veffels, by which the bones and all the parts belonging to them are nourifhed: it likewife fupports a vaft number of nervous filaments, by which fenfation is communicated not only to this and to the internal membrane of the bones, but even, in fome degree, to fome portions of the bones themfelves. *Winflow*'s Anat. p. 116.

PERIPHALLIA, περιφαλλια, in antiquity, the fame with *phalagogia*. See PHALLAGOGIA and DIONYSIA.

PERIPLOCA, in botany, the name of a genus of plants, the characters of which are thefe: the flower confifts of only one leaf, and is very open at the mouth, fo as to refemble a wheel; from the cup there arifes a piftil, which is fixed like a nail into the back part of the flower, and ripens into a fruit fo like that of the *apocynum* or dog's bane, that authors in general have confounded the two genufes. The pod is long, and is compofed of two vaginæ, and fplits open lengthwife from the bafe to the apex. *Tourn.* Inft. p 93.

The fpecies of *periploca*, enumerated by Tournefort, are thefe: 1. The long-leaved *periploca*, with purple flowers. 2. The long and narrow-leaved one, called by the Ægyptians *fecamone*. 3. The *periploca* of Monpelier, with roundifh leaves, called by many authors *fcammonia Monfpeliaca*. 4. The Montpelier *periploca*, with fharp pointed leaves. 5. The American *periploca*, with a fomewhat echinated fruit 6. The broad American *periploca*, with a hard, oblong, fmooth and tumid pod. 7. The white flowered climbing *periploca* of America, with very narrow willow-like leaves. 8. The low fpreading American *periploca*, with leaves like thofe of toad flax. 9. Citron-leaved umbelliferous creeping *periploca* of America, with red flowers. 10. Creeping white-flowered American *periploca*, with leaves like thofe of money-wort. 11. Citron-leaved climbing American *periploca*, with a very large fruit. And, 12. The climbing bindweed-leaved American *periploca*, with an alated fruit.

PERIPLYSIS, a name given by fome authors to a diarrhœa, in which the ftools are extremely thin and watry, and very frequent and large in quantity.

PERIPNEUMONY *(Cycl.)*.—This difeafe is very frequently confounded with the pleurify, and then one is miftaken for the other, fometimes even by phyficians. As this, however, is a diforder of the lungs, and the other of the pleura, there are fymptoms attending them by which they may be certainly diftinguifhed. See PLEURISY.

PERIPYEMA, a word ufed by chirurgical writers to exprefs a collection of matter, wholly furrounding any part.

PERIRRHANTERION, περιῤῥαντηριον, in antiquity, a veffel, ufually of ftone or brafs, filled with holy water, with which all thofe that were admitted to the facrifices were fprinkled; and beyond which it was unlawful for any one that was βεβηλος, or profane, to pafs. Some fay it was placed in the Αδυτον, or inmoft recefs of the temple, into which none entered but the prieft: but Cafaubon will have it to be placed at the door of the temple, which opinion feems moft probable, becaufe all perfons who were Αβεβηλοι, or unpolluted, were permitted to pafs beyond it. *Potter*, Archæol. Græc. l 2. c. 2. T. 1. p. 189.

PERISCYLACISMUS, περισκυλακισμος, a method of purification in frequent ufe among the Greeks. It was done by drawing a whelp round the perfon to be purified. *Potter*, Archæol. Græc. T. p. 223 The word comes from σκυλαξ, a whelp.

PERISSON, in botany, a name given by the antient Greeks, and afterwards by the Romans, in the time of Pliny, to a kind of night-fhade, which made thofe people who took it internally run mad. It was called alfo *pentadryon* and *anhydron*, and by fome *manicum ftrychnum*, or fimply *manicon*. See the article STRYCHNUM.

PERISSOSIS, a word ufed by Hippocrates to exprefs a redundance of humours.

PERISSOLOGY, περισσολογια, in rhetoric, a quality of ftile directly oppofite to *brachylogy*, and is otherwife called *macrology*. See MACROLOGY, BRACHYLOGY, and DICTION.

PERISTERION, in botany, a name given by fome authors to the *fcabiofa minor*, or fmall fcabious. *Ger.* Emac. Ind. 2.

PERISTERITES, the *pigeon-ftone*, in natural hiftory, a name given by fome whimfical people to an odd conformation of a pebble, which they fuppofe to reprefent very exactly a pigeon without its wings. It feems to have been a mere *lufus naturæ*, in the formation of a common pebble. The variations of figure in the common pebbles are fo infinite, that a perfon of a fertile imagination might find refemblances to all the parts of the creation in the ftones of a fingle gravel-pit. The giving names to fuch accidental things is not only unneceffary, but mifchievous, as it caufes great confufion in natural hiftory.

PERISTERNA, in anatomy, is ufed for the lateral parts of the thorax.

PERISTIARCHUS, περιςιαρχος, in antiquity, a name given to the perfon that officiated in a luftration. *Potter*, Archæol, Græc. T. 1. p. 35.

The word comes from Περιςια, another name for Καθαρμαλα.

PERISTOMA, in anatomy, a word ufed by authors to exprefs the villous coat of the inteftines.

PERISTYLION, περιςυλιον, among the Athenians, a large fquare place, tho' fometimes oblong, in the middle of the *gymnafium*, defigned for walking, and the performance of thofe exercifes which were not to be performed in the *palæftra*. *Pott.* Archæol. Græc. l. 1. c. 8. T. 1. p. 39.

PERITERE, in architecture, a place encompaffed round with columns, and with a kind of wings about it. Here the pillars ftand without, whereas in the periftyle they ftand within.

PERITEXIS, a word ufed by the old medical writers to exprefs a colliquation.

PERITHE, a name by which fome of the writers of the middle ages have called the *pyrites*; they fay it has great virtues againft the gout: fome of them alfo have called it the *lapis peridonius*.

PERITONEUM *(Cycl.)*—In the fifh kind, the *peritoneum*, or membrane furrounding the abdomen, is very varioufly coloured. In fome it is of a fhining filvery whitenefs, as in the cyprini, perch, efoces, &c. In others it is of a fine pale flefh colour, as in the falmon; and in fome it is wholly black, or elfe variegated with very numerous black fpots, as in the clupeæ, gadi, cotti and fpari. *Artedi*'s Ichthyolog.

PERIWINKLE, in natural hiftory, the Englifh name of a fpecies of fhells, called by authors *buccina*. See BUCCINUM.

PERIWINKLE, *pervinca*, in botany. See PERVINCA.

PERIZOMA, a word ufed by fome authors for a trufs.

PERMISSION, *permiffio*, in rhetoric, a figure which differs in nothing from *conceffion*, except that the latter relates only to argument and pleading, but the former to action: E. G. *Quoniam, omnibus rebus ereptis, folum mihi fupereft animus et corpus: hæc ipfa, quæ de multis relicta funt, vobis et veftræ condono poteftati. Vos me quo pacto vobis videtur, utamini, atque abutamini; licebit impune. In me, quicquid libet, ftatuite*, &c.

PERNIONES, *childblains*. When thefe tumours tend to fuppuration, it is proper to treat them like other recent abfceffes; the beft method is firft to cleanfe the wound with fome digeftive ointment, then to drefs it with balfam of Peru, or other the like application; and laftly, to apply fome of the lead or litharge plaifters. Oil of myrrh *per diliquium* is alfo found of vaft fervice in thefe cafes, as is alfo the applying a comprefs dipped in a mixture of equal parts of lime-water and camphorated fpirit of wine, over the other remedies.

In people who have been ufed to be afflicted with *chilblains* at the return of a certain feafon, it will be found a great prefervative againft thofe troublefome tumours, to anoint the parts where they are expected to appear, both before and during the accefs of the fevere cold, with oil of turpentine or petroleum; and when the diforder firft begins to fhew itfelf, it is a very good method to wrap round the affected part a piece of a hog's bladder, well wetted with one or other of thofe oils, and care taken to keep off the cold. *Heifter*'s Surg. p. 211.

PERODACTYLÆUS, in anatomy, a name given by Riolan and others to one of the mufcles of the foot, called by Albinus the

the *flexor longus digitorum pedis*, and by Winflow, the *perforans pedis*, and the *acceſſorius perforantis pedis*.

PERONÆUS (*Cycl.*)—PERONÆUS *maximus*, a mufcle of the leg, commonly called *peronæus poſterior*.

It is long and penniform, and lies on the fibula. It is fixed above to the anterior and outer part of the head of that bone, and to a fmall portion of the head of the tibia; then to the outfide of the neck of the fibula, to the upper half of the external angle of that bone, and to the aponeurofis tibialis; which at that place makes a feptum between this mufcle and the extenfor pollicis; from hence turning backward according to the direction of the bone, it forms a confiderable tendon; which running down behind the external malleolus is inferted in the fide of the bafis of the firft metatarfal bone, and a little in the bafis of the os cuneiforme majus. *Winſlow's* Anatomy, p. 221.

PERONÆUS *medius* This is commonly called *peronæus anticus*, and is a long mufcle fituated anteriorly on the middle part of the fibula. It is fixed above by flefhy fibres to more than the middle third part of the anterior or outfide of the fibula, and to the neighbouring part of the aponeurofis tibialis. It is likewife fixed to a production from the infide of that aponeurofis, which runs to the upper part of the tibia, and there ferves for a middle feptum between this mufcle and the extenfor digitorum longus; from thence it runs down and forms a tendon, which going in the direction of the oblique line of the fibula, paffes behind the external malleolus, and then thro' an annular ligament common to it and to the *peronæus maximus*, and is afterwards inferted in the tuberofity, at the bafis of the fifth metatarfal bone, fending off a fmall tendon to the firft phalanx of the little toe. *Winſlow's* Anatomy, p 218.

PERONÆUS *minimus*, a fmall mufcle vulgarly thought to be a portion of the extenfor digitorum longus, tho' it is eafily feparable from it.

It is fixed by flefhy fibres in the lower half of the infide of the fibula, between two oblique bony lines, on one fide of the lower part of the extenfor digitorum longus, to which mufcle it is fimply contiguous; from thence it runs down, contracting in breadth, and paffes, with the extenfor longus, thro' the common annular ligament, forming a flat tendon, which foon feparates from thofe of the extenfor, and is inferted near the bafis of the fifth metatarfal bone. It is diftinguifhed from the other two *peronæi* by a feptum, or production of the ligamentary aponeurofis of the tibia. *Winſlow*, Ibid.

PEROQUETTE, in zoology, the name of a fmall fpecies of the *pſittacus* or parrot kind, with a long tail.

There are feveral kinds of this bird: 1. The common, which is green, red, and yellowifh, and was the firft fpecies of parrot brought into Europe, and well known among the antients. 2. The *peroquette*, which is green all over, without any variegation. 3. The pale, green, and red kind. 4. The red and green crefted kind. 5. The red kind, with wings variegated with black and green.

Befide thefe, Marggrave has defcribed feven other Brafilian kinds, called the *tuiaputejuba*, *tuitirica*, *jendaya*, *tuiete*, *tuipara*, *anaca*, and *quijubatui*, which fee under their feveral names; and two others, to which no particular name has been given; one of the fize of a fwallow, all over green, with a black beak and a very long tail; and the other of the fize of a ftarling, of a deep green on the back, and paler green on the belly, and with a fhorter tail. *Ray's* Ornithology, p. 76, 77, 78.

PERPENDICULAR-*roots*. See FIBROSE-*roots*.

PERSIAN-*ſhell*, a fpecies of dolium. See DOLIUM.

PERSICA, the *peach-tree*, in botany, the name of a genus of trees, the characters of which are thefe: The flower is of the rofaceous kind, being compofed of many petals, arranged in a circular form. The piftil arifes from the cup, and finally becomes a flefhy fruit of a roundifh figure, fulcated lengthwife, and containing a ftone rough and full of irregular holes, containing an oblong kernel.

The fpecies of *peach*, enumerated by Mr Tournefort, are thefe: 1. The common green white foft flefhed *peach*. 2. The double flowered *peach*. 3. The *peach* with blood-red juice. 4. The hard *peach*, with white or flefh-coloured pulp. 5. The hard *peach*, with box-coloured pulp. 6. The fummer apricot *peach*, or john *peach*. 7. The early ripe *peach*. 8. The fine flavoured corbelian *peach*. 9. The hardeft *peach*. 10. The paler *peach*. 11. The *peach* with fweet-fcented fruit, with a fmooth fkin. 12. The *peach* with a round, dufky red, very fweet-tafted fruit. 13. The *peach* with a large round firm fugar-like fruit. 14. The large round yellow late *peach*, called the *admirable yellow*. 15. The *peach* with large round blackifh late-ripening fruit. 16. The great fcarlet *peach*. 17. The *peach* with a fruit variegated with purple and red, and of a rich vinous tafte. 18. The early violet-coloured vinofe *peach*. 19. The *peach* with red, roundifh-flatted fruit, with red flefh. 20. The dwarf African *peach*, with fingle flefh-coloured flowers. 21. The dwarf African *peach*, with double flefh-coloured flowers. *Tourn.* Inft. p. 614. See PEACH.

PERSICA *concha*, in natural hiftory, a name given to a very remarkable and beautiful fea fhell, which authors have long been at a lofs to reduce to any genus.

Aldrovand has thrown it to the end of his work, and fays, it would be of the turbinated kind, if it did not want the turba. It is truly of the genus of the *concha globoſa*, or *dolium*. See DOLIUM.

PERSICA *terra*, in natural hiftory, an earth of the ochre kind, known in the colour fhops of London by the name of *Indian red*.

It is a very fine purple ochre, of a confiderably compact texture, and great weight; while in the earth it is of a pure blood colour, and is not to be cut with the fpade, but is dug with iron crows, and falls in irregular maffes. It is of a rough dufty furface, and full of confiderably large bright glittering particles: thefe are white and of a fine luftre. It adheres firmly to the tongue, is rough and harfh to the touch, ftains the hands very deeply, and is of a rough aftringent tafte, and makes a very violent effervefcence with acid menftruums.

It is dug in the ifland of Ormuz, in the Perfian gulf, and in fome parts of the Eaft Indies. *Hill's* Hift. of Foff. p 58.

PERSICARIA, *arſmart*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the apetalous kind, confifting of feveral ftamina which arife from a cup divided into feveral fegments. The piftil finally becomes a fruit of a flatted oval figure, and pointed at one end, and contained in the capfule, which was the cup of the flower.

The fpecies of *perſicaria*, enumerated by Mr. Tournefort, are thefe: 1. The common mild or fpotted *arſmart* 2. The fpotted *arſmart*, with fpots of the figure of a horfe-fhoe. 3. The mild *arſmart* without fpots. 4. The white flowered mild *arſmart*. 5. The burning *arſmart*, or water pepper. 6. The burning *arſmart*, with white flowers. 7. The leffer *arſmart*. 8. The white flowered leffer *arſmart*. 9. The narrow-leaved *arſmart*. 10. The long and narrow-leaved *arſmart*, called the *long-leaved and water pondweed*. 11. The long-leaved Valentia *arſmart*. 12. The *arſmart* with leaves huary underneath. 13. The great dock-leaved *arſmart*, with purple cups. 14. The black-leaved alpine *arſmart*, with white cups. 15. The *arſmart* with lepidium leaves. 16. The long procumbent *arſmart*, with narrow not fpotted leaves, and long flender fpikes. 17. The white flowered fhrub fpotted Virginian *arſmart*. 18. The fhrub fpotted Virginian *arſmart*, with flefh-coloured flowers. *Tourn.* Inft. p. 509.

The common *arſmart* without fpots, is by fome efteemed a good diuretic, but it feems too acrid to be given internally without great caution. Externally it is ufed by many in cataplafms againft indurated tumors, and in inveterate ulcers. That with fpotted leaves has no virtues.

PERSOLATA, in botany, a word ufed by Pliny as the name of a kind of burdock, different from the *perſonata*.

He has, in the beginning of the chapter, fpoken of the arcium of the Greeks, which he fays the Latins fometimes called *perſonata*, and afterwards adds this *perſolata*; which, he fays, was a plant vulgarly known and called by the Greeks *arcium*.

He feems to allow, that the Greeks called both thefe plants by the fame name; but he diftinguifhes the *perſolata* from *perſonata*, by faying that the former has leaves like thofe of the great gourd, but larger and more hairy. It is probable, therefore, that he diftinguifhes under thefe two names, the two different fpecies of the great burdock common with us, the one with fimple, the other with woolly heads.

PESONATA, in botany, a name by which fome have expreffed the common great burdock. *Bauhin*, v. 3. p. 111.

PERSONATED-*flower*. See PERSONATI, *Cycl.*

PERSPECTIVE (*Cycl.*)—*Military* PERSPECTIVE, that wherein the eye is fuppofed to be infinitely remote from the table or plane.

PERSPICUITY, *perſpicuitas*, in rhetoric, is a principal virtue of ftile, to which all the ornaments and beauties of fpeech ought to give way.

A difcourfe is equally obfcured by too much concifenefs and profufenefs. (See BRACHYLOGY and MACROLOGY.) Several rhetorical figures are likewife deftructive of *perſpicuity*. See *Voſſ.* Rhet. l. 4. c. 1 p 30, feq.

PERSPIRATION (*Cycl.*)—*Perſpiration* is influenced by the paffions of the mind. Thus anger and joy increafe, and fear and fadnefs leffen both *perſpiration* and urine. Anger caufes a ftrong motion in the membranes of the heart, and quickens its contraction and dilatation, and thereby quickens the contraction and dilatation of the blood veffels and fecerning ducts, and of confequence increafes the difcharges of *perſpiration* and urine; and that more or lefs, in proportion to the ftrength and continuance of the paffion.

Joy affects thefe difcharges in like manner as anger. In the paffions of fear and forrow, *perſpiration* and urine are leffened; by the depreffion of the activity of the foul under thofe paffions. Dr *Bryan Robinſon* of the Food and Difcharges of Hum. Bodies, p. 77, feq.

The proportion of *perspiration* to urine is increased by all those exercises which increase the motion of the blood, and warm the skin. Dr. *Bryan Robinson* of the animal Œconomy, p. 280.

We have an account of a person, who by passing many nights in astronomical speculations, had his *perspiration* so obstructed by the cold and damp of the air in Holland, that a shirt he had worn for five or six weeks was as clean as if it had been worn but one day. The consequence of this was, that he gathered subcutaneous waters, but was cured in time. Phil. Transf. N° 8. p. 138.

We have several observations, experiments, and tables, relating to the quantity of *perspiration*, urine, and stool, in South Carolina, by Dr. John Lining. See Phil. Transf. N° 470 and 475.

PERTICA, a sort of comet, being the same with *Veru.* See the article VERU.

PERTICA, among the Romans, a long rod for beating the fruit from trees. It was likewise used for a long measure. See PERCH, *Cycl.*

PERVIGILIA, in antiquity, an appellation given to nocturnal festivals, celebrated in honour of several deities, as Ceres, Venus, Fortune, *&c.* They were so called because the nights were spent in waking.

PERVINCA, *periwinkle*, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, and is of the funnel-shaped kind, but so very wide at the mouth, that it approaches to the saucer-shaped ones, and is divided into several segments at the rim. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this, afterwards, becomes a seed vessel, composed of two capsules, containing an oblong seed, usually of a cylindric figure, and fulcated. See Tab. 1. of Bot. Class 2.

The species of *pervinca*, enumerated by Mr. Tournefort, are these: 1. The common broad-leaved *periwinkle*, with blue flowers. 2. The common broad-leaved *periwinkle*, with white flowers. 3. The common narrow-leaved *periwinkle*, with blue flowers. 4. The common narrow-leaved *periwinkle*, with white flowers. 5. The common narrow-leaved *periwinkle*, with red flowers. 6. The common narrow-leaved *periwinkle*, with double blue flowers. 7. The common narrow-leaved *periwinkle*, with double flowers, of a deep purple. 8. The variegated double flowered *periwinkle*. 9. The broad-leaved variegated *periwinkle*. And 10. The narrow-leaved variegated *periwinkle*. The tree called *padrus*, approaches very much to this genus. *Tourn.* Inst. p. 119.

The *pervincæ* are easily known, even when not in flower or seed, by their branches being long and trailing, and their leaves smooth and glossy, and approaching to the shape of bay-leaves. These plants seldom ripen their fruit; and the way to make them do it is, to plant them in a small pot, and cut off all the trailing branches; by which means the nourishment will be carried up to the ripening the fruit. *Tourn* Inst. p. 120.

PERUVIAN *bark* (*Cycl.*)—The virtues of this medicine are at this time sufficiently known; but the largeness of its dose in the common forms of powder, or infusion in wine or in water, are great disadvantages; and our common method of giving it in the extract or resin, as we prepare them, not certain, and have their inconveniency.

Mr Geoffroy has attempted a method of giving the *bark* in all its efficacy, without its ill taste, and in one third of the usual dose, by means of his dry extract; twenty four grains of which, it is very certain, contains the whole efficacy of a dram of the choicest *bark* in powder; and is found by experience to be wholly as efficacious, as certain, and as speedy, and really possesses all that the juices of the stomach can extract from thrice the quantity of powder, without loading it with so large a quantity of useless matter.

The experiments this gentleman made to be assured of what was the efficacious, what the useless part of the *bark*, and what the quantity of each in the whole, were these. He put into a matrass a dram of choice *bark* in fine powder, and pouring on it an ounce and a half of rectified spirit of wine, set the vessel in a balneum mariæ till the spirit was high coloured, and had extracted all the tincture it could, and filtering this tincture, and evaporating it on a China-plate in a balneum mariæ, he obtained twenty grains of a dry extract; and then putting on two ounces of water on the remaining powder, he drew what tincture he could by this means, and evaporating that in like manner, he obtained three grains and a half of extract in the like dry form.

Thus, by the nicest process, twenty-four grains were all that could be separated of the efficacious matter from a dram of *bark*, and the remaining powder, which was perfectly insipid, weighed as much as was required to make up the dram, excepting six grains, which the author supposes to have been the fibrous and insipid powder remaining in the filtre.

Hence it appears very evident, that when we take the *bark* in substance, it is only about a third part of what we are forced to swallow that can be of any use to us; and that the same portion is all we can expect in the virtues of any decoction or infusion of it.

The resin of the *bark* is of such a nature, that it is capable of being penetrated by, and suspended in boiling water, poured on the substance in fine powder; and so long as this water retains a certain degree of heat, it remains suspended and invisible in it, and the water is of a clear brownish colour; but when the liquor becomes cooler, the resin can be no longer suspended, the whole becomes milky, and the resin precipitates itself.

Wine, which is a liquor partly aqueous, partly saline, and partly spirituous, is a menstruum much properer to extract the virtues of the *bark* than mere water, as it is much more able to dissolve the juices or sap condensed and inspissated in the *bark* of the tree; and for this reason a strong infusion of *bark* in this menstruum remains clear, and keeps the resin suspended when cold. Thus it is the fire alone which can suspend the resin in a watry infusion of the *bark*; and in a vinous one, the spirituous and inflammable part of the liquor does the same thing: and as the resin of the *bark*, which there is great reason to believe possesses all the virtues of that medicine, is wholly precipitated from watry infusions when cold, it is plain that there can be very little dependance placed on the common clear infusions in this menstruum: the remaining taste in these infusions is only a faint bitterness, which arises from the gummose and saline parts of the dried juices of the *bark*; the whole concrete which alone possesses the virtue of the medicine, being of the nature of those bodies properly called *gum resins*; which are but very imperfectly soluble in water, and of which wine is the proper dissolvent.

In making the dry extract by means of water, the same author put a dram of fine powder of pick'd *bark* into a large quantity of water, and keeping it in a considerable heat in a matrass twenty-four hours, and after that, filtring the liquor as hot as possible, that the resin might not coagulate, he set it to evaporate on a balneum mariæ in China-vessels; the resin soon began to separate itself, and a pellicle appeared on the surface of the liquor, of all the changeable colours of the breast of a pigeon; and this covering the extract when dry, made it appear as if gilt or browned over. This infusion from a pint and half of liquor, yielded twenty grains of extract perfectly dry; and an ounce and half of spirit of wine being poured on the remaining powder, when it had extracted all the tincture it could, left only three grains of extract; so that the result of this process was much the same with that begun with spirit of wine; and from the whole it appears very evident, that by this method of management, the whole virtue of the *bark* may be given in a third part of the dose. Memoirs Acad. Science Par. 1738.

Peruvian-bark has been found very effectual in preventing colds. The method in which it was used, in a case mentioned in the Philosophical Transactions, was, after due preparation, by bleeding or purging, to take two ounces of it every spring and fall. By this method, an habitual taking of cold, and a consequent sore throat was cured. Phil. Transf. N° 478. p. 3.

We have many accounts of the great effects of the *peruvian-bark* in the cure of gangrenes and mortifications. See Med. Ess. Edinb. Vol. 3. Art 5. or its Abridgment, Vol. 1. p 175, seq. We have also several accounts of the good effects of this medicine in ulcers and the small pox. See Med. Ess. Vol. 5. Art. 10. or Abridgment, Vol. 1. p. 187.

Many instances are recorded in medical writers of the jaundice, dropsy, asthma, and all the train of nervous disorders, brought on in a surprisingly short time after an injudicious administration of the *bark*: among others the curious may consult the Med. Ess. Edinb. Vol 4. Art. 24.

The *peruvian-bark* is discovered to be effectual in the cure of mortifications from an internal cause. The history of this discovery is: In 1715, Mr. Rushworth, surgeon in Northampton, gave it to a patient labouring under a mortification; and having afterwards other proofs of its good effects in this disease, communicated his discovery in 1731. Mr. Amyand soon tried it in such cases, and found it successful in seven. Mr. John Douglas confirmed this by the history of a patient of his, which he published in 1732; and Mr. Shipton soon after related his success by this medicine, to the Royal Society. Mr. Rushworth and Mr. Amyand confine its use to mortifications, from an internal cause; the former thinks it is not proper in all cases of that kind, particularly where there is no intermission of the fever. Mr. Douglas seems to think it will succeed in all mortifications. All these three gentlemen gave half a dram for a dose every fourth hour. Mr. Shipton increased the dose to two scruples, and gave it while the fever continued. He proposed to have it tried in nomæ, phagedenæ, herpes, or other chironian ulcers. Mr. William Arrot, who lived a considerable time in Peru, describes the tree from which the *peruvian-bark* is got.

It grows in the country between two and five degrees south latitude; it is tall, without branches to near the top, where it spreads out into a hemisphere; its bark is of a dark colour on

on the outfide; its leaves refemble thofe of a plum-tree. There are four forts of the *bark*, the reddifh, the yellowifh, the curling, and the whitifh. The two firft are the beft kinds; the curled is got from young trees, and the white foon becomes infipid. The beft fort grows about the city of Loxa. The Indians flice off the *bark* from the trees, and carry it to houfes to be dried [a]. M. de la Condamine [b] fays this tree is called *caſcarilla*, and is very different from the *quina quira*. [[a] See Phil. Tranf. N°. 446. fect. 1. [b] Mem. de l'Acad. des Scienc. 1738.]

PERYGUA, in botany, a name given by fome authors to a plant of the caffine kind, called the *caffioberry* bufh, and by fome the *Paraguay tea*. *Dale* Pharm. p. 319.

PERYSIAS, a word ufed by authors to exprefs wine of the laft year's vintage.

PES (*Cycl.*)—PES *leonis*, in botany, a name by which fome authors exprefs the *alchymilla*, or ladies mantle. *J. Bauhin*, V. II. p. 398I. *Chebræus*. 172.

PESCE *vacca*, the *cow-fifh*, a name given by Auguftino Scilla to a kind of dog-fifh, not defcribed by any author before his time, but accurately drawn by him in his book on petrifactions, on occafion of its teeth: many fpecies of the *gloſſopetræ* of the ifland of Malta, and other places, being plainly the fame with the teeth in the jaws of this fifh.

PESSOMANTIA, Πεσσομαντεια, in antiquity, the fame with *chiromantia*, which fee.

PESTERABLE, in our old writers, an epithet for fuch wares as *pefter*, or take up much room in a fhip. Stat. 32 *Hen.* VIII. c. 14. *Blount*, *Cowel*.

PESTILENTIAL *buboes*. By *buboes* in *peſtilential* cafes, the writers in phyfic not only exprefs fuch tumours as arife under the arms, under the ears, and in the groin; but comprehend under this term thofe alfo which are fituated in the neck, breaft, arms, legs, and other flefhy parts of the body, which fwell and inflame in *peſtilential* fevers, and feem the confequences of the endeavours of nature to throw out the peftiferous matter which lay concealed in the body.

Peſtilential buboes are diftinguifhed from other tumors by their happening at a time and in conjunction with the plague, and from their being accompanied by the fymptoms proper to that difeafe. Thefe tumours appear fometimes fooner, fometimes later, in the courfe of the difeafe; in fome they appear before the patient knows he has the infection, and in others two or three days elapfe before their appearance: they are very feldom known to appear later than on the fourth day, and are fometimes joined with carbuncles; but tho' the *buboes* frequently appear without thefe, yet the carbuncles never appear without tumors.

Perfons who have thefe tumors come on without any very bad fymptoms, and have them maturate fpeedily, are in general the fooneft freed from the diftemper, infomuch, that the beft method of giving relief in this terrible difeafe, confifts in the carefully promoting and keeping up the *buboes* and tumors. All difcutient or difperfing medicines are carefully to be avoided, and the phyfician's bufinefs is to affift nature in the throwing out, and moft fpeedily bringing thefe tumors to fuppuration.

The patient is to be confined to his bed on the firft appearance of thefe, and with the help of internal medicines proper to haften the fuppuration of tumors, the parts affected are to be rubbed pretty ftrongly with the hands or cloths, and external, maturating and emollient cataplafms to be applied; of this kind is that of yeaft, falt, and muftard-feed, all mixed together, or of yeaft alone: by means of thefe the tenfe parts are relaxed and ftimulated, and the fuppuration greatly promoted; as alfo by the cataplafms of roafted onions, with Venice-treacle and butter; or of crumb of bread, with milk and faffron. Plaifters are alfo very ufeful on fome occafions, in thefe cafes, as the frequent renewal of the cataplafms expofes the patient too much to the external air, and thefe are not attended with that inconvenience.

The moft famed plaifters on thefe occafions are that of Barbet, made of the diachylon, with the gum and mucilage plaifter, of each half a pound; muftard feed in powder, three ounces; bafilicon, four ounces, all mixed and made into a plaifter: and that of Dr. Hodges, made of three ounces of oxycroceum, an ounce of galbanum, the fame quantity of gum caranna, and two ounces of black pitch, reduced to the confiftence of a plaifter.

This may be ufed like the former; nor is that plaifter to be efteemed a trifle, which is made of honey, flour, and the yolks of eggs.

Bliftering and cupping, fo much ufed by the antients to forward fuppuration, are entirely laid afide by the modern phyficians: but the celebrated German phyfician, Beintern, afferts, that *peſtilential buboes* have been very frequently difcuffed, without being brought to fuppuration, by the application of warm afhes alone; and that with very happy fuccefs: and he obferves, that in this cafe the *peſtilential* venom is not abforbed into the blood again, but is attracted and carried off by the afhes.

In fome cafes in this terrible diftemper, the tumor comes to fuppuration in a few days; in others it is fome weeks before it can be brought to it, by all that can be done. When thoroughly fuppurated, it is to be opened with the fcalpel, if it does not break of itfelf; and after thus opening, when the matter has been difcharged, it muft be well cleanfed. The beft digeftive in this cafe is the common ointment ufed on that occafion, mixed with a fmall quantity of Venice treacle, and balfam of fulphur made with oil of turpentine. At each dreffing the matter is to be gently fqueezed out of the abfcefs, and the ointment applied without tents, unlefs the opening prove very narrow; then applying over all a plaifter of the common diachylon, or of honey and flower, the whole may be bound on, and this dreffing continued till it is a proper time to heal with fome vulnerary balfam.

There has been much difpute between the phyficians of different ages about the proper time for opening *buboes* of this kind; fome have been for making an immediate incifion, and others even for extirpating the whole fwelling, as foon as it appeared, by means of the knife; but the firft of thefe methods has been found to be frequently attended with the ill confequences of ill conditioned fiftulæ, ftiffnefs, and lofs of motion in the limb, and fometimes even with mortifications and gangrene; and the other too harfh, and dangerous in many parts of the body: and the prefent practice univerfally difallows both methods, being always for bringing the fwelling to fuppurate. *Heifter*'s Surg p. 200.

The poifon of the matter of thefe fores has been nicely and boldly enquired into, as to its nature and properties, by Dr. Alpranus of Prague, in the time of the plague there in 1680. This gentleman having launced a *peſtilential* boyle, collected the matter from it, and putting it into a retort, luting the junctures with the receiver very clofely and exactly, and applying by proper gradation the feveral degrees of fire; at firft there came over a water, then a more fat and vifcid liquor, of an oily nature; and laftly, there appeared in the neck of the retort, a falt.

The fire being taken away, and the veffels cooled, the Doctor prepared himfelf for the opening of them by ftopping his ears with cotton, his noftrils with peffaries, and his mouth with pieces of fpunge, all foaked in vinegar and Venice treacle. The moment the veffels were opened, however, there proceeded out of them a ftench more horrible than can be conceived, and ftriking the Doctor with an univerfal trembling, in fpite of his defence. He proceeded, however, to break the neck of the retort, and feparating the fœtid falt from it, he ventured himfelf to tafte it, and defired Mr. Refhel, the perfon from whom the matter was obtained, to do the fame: it was found to have a moft dreadfully piercing acrid tafte, which the Doctor compares to that of *aqua regia*.

Hence he infers, that the moft terrible fymptoms of this fatal difeafe are to be accounted for: the ftomach, wounded by fo acrid a juice as this mingled among the blood, naufeates food, and is afflicted with continual vomitings: the guts, infefted by the fame unwelcome gueft, are thrown into violent perturbations, whence arife thofe diarrhœas which often accompany the patient to his death; and from the horribly acrid quality of this juice, it is no wonder that fuch piercing pains are found in the *buboes*, and fuch burnings in the carbuncles that attend this difeafe.

Hence alfo, as he obferves, it is, that fudorifics are the beft remedies, fince they allay the acrimony, and tend to expel the venomous juices thro' the pores. In this ficknefs at Prague this gentleman obferved, that almoft all who fweat plentifully recovered, whereas thofe who did not fweat, were moftly taken off. *Hook*'s Philofoph. Collect. N°. 2. p. 18.

PESTILENTIAL *carbuncle*. This is an inflammation that arifes in time of *peſtilential* contagion, with a veficle or blifter, almoft like thofe which are caufed by burning; but this inflammation generally terminates in a mortification, and putrefies the adjacent parts down to the bone, all about becoming as black as a coal.

This kind of inflammation always breaks out very fpeedily, fometimes even in an hour or two, attended with the moft intolerable heat and pain. On opening it, there is always difcharged a darkifh limpid or watry fanies, and the flefh underneath is of a black colour, the mortification having then already feized it, and fpreading more and more by degrees; but in thofe who recover, the mortification at length ftops, and the putrefied flefh fuppurates, and parts from the found.

The fize and number of thefe inflammations in the fame patient, are both very various and uncertain; there is no part of the body but what they may infeft, and they are generally, if not always, accompanied by buboes.

The immediate caufe of thefe is a violent inflammation, excited in the blood by the *peſtilential* venom; and the inflammation, from the nature of the cafe, is ever fpeedy, and always followed by fphacelation and corruption of the parts. What is remarkable is, that the parts and juices do not fuppurate into matter, as is ufual in other tumors, but whatever is internally corrupted, feparates and entirely falls off: for the inflamed parts fuppurate at the margin of the inflammation, fo that if the patient does not die fuddenly, the fphacelated parts are feparated, and naturally thrown off.

Carbuncles are always a worfe fymptom than buboes in thefe

cafes, efpecially if the eruptions turn directly either livid or black; but if they are red firft, and then gradually turn to a citron colour, the danger is lefs.

Thofe *carluncles* alfo which arife in the face, neck, breaft, or arm-pits, are always accounted the worft, and ufually kill the patient.

The chief bufinefs of internal medicines, in this cafe, is to keep the patient in a conftant breathing fweat; and the bufinefs to be aimed chiefly at in external applications, is to procure, as foon as poffible, the feparation of the fphacelated parts from the found. Some, therefore, ufe fcarification alone in this cafe, and that with very good fuccefs; for, by making a great number of incifions in the corrupted parts, they let out the *peftilential* venom which corrupted the blood. Others only open the blifters, and afterwards wafh the parts with a mixture of camphorated fpirit of wine and Venice treacle, and afterwards apply a maturating cataplafm, made of four fpoonfuls of honey, three fpoonfuls of yeaft, the yolks of two eggs, and half an ounce of foap, which are all to be mixed and applied warm to the part: others on the fame occafion ufe alfo, as a cataplafm, a mixture of two ounces of flour and half an ounce of vinegar, made with water or fkimmed milk into a proper form, and with an ounce of honey, and an ounce of powder of faffron, thofe ingredients are to be thoroughly mixed in, and the cataplafm to be applied warm, and renewed frequently, till the whole carbuncle feparates and falls off from the found parts; and this is a much better and fafer method of extirpating the *carbuncle*, than by cutting it out at once, by which operation fome have been known to have been killed upon the fpot. When the greateft part of the *carbuncle* is, however, of its own accord feparated from the found parts, the part where it adheres may always be fafely divided with the fcalpel; and this, indeed, is abfolutely neceffary.

If an ill-conditioned and luxuriant flefh grows internally in this cafe, either of itfelf, or from the extirpation of the *carbuncle* being made too foon, this muft ever be neceffarily entirely confumed by the application either of the Ægyptian ointment, or of the following: Take two fpoonfuls of honey, the yolks of two eggs, and of burnt alum, gentian, and birth wort root in powder, each an ounce, make the whole into an ointment.

If the inflammation inclines the adjacent parts to a gangrene, it will be moft proper to ufe the following application: Take falt of wormwood, half an ounce of the herb fcordium, and of elder and chamomile-flowers each a handful, and of river water two pints and an half; when thefe have been well boiled and ftrained, mix with the liquor fix ounces of camphorated fpirit of wine, and two ounces of Venice treacle; and let this be applied hot to the parts by means of double linnen rags being well wetted in it, and repeated frequently till the violence of the inflammation abates.

When the mortified flefh of the carbuncle has feparated itfelf from the found part, it is neceffary to cleanfe the ulcer perfectly with digeftive ointments, left any of the matter remain there, and mix itfelf again by degrees with the blood; and this deterging of the ulcer is always to be continued till there remain no more fymptoms of the *peftilential* infection in the patient; and after this the wound may be healed like other ulcers.

In the laft great plague in London, and in many other the like cafes, it was found the beft and happieft method with *carbuncles* to extirpate them at once by the actual cautery, or red hot iron, till the dead parts being burnt to the quick ones beneath, there were no relicts of the *carbuncle* left in the patient. And in fome cafes this may be a very proper method, but there are others where prudence will not allow the ufe of it; as where the patient is too much terrified by it, where the parts on which the carbuncle is fituated are of the utmoft tendernefs and confequence: in thefe it will be readily determined, that the milder treatment before advifed muft be greatly preferable.

Another famous remedy is the applying to the parts butter of antimony. The circumjacent parts being anointed with this, the diforder is prevented from fpreading, and an efchar is readily made, which divides the found from the corrupted parts, and at length wholly feparates and throws off the latter.

There are not wanting, however, phyficians who are againft the ufe of butter of antimony on thefe occafions; but where the actual cautery might have been applied, this furely is a fomething milder, and not much lefs effectual remedy. *Heifter*'s Surg. p. 205.

PESTILENTIAL *difeafes*. Many think that the caufe of all thefe is in the air, and is exhaled in vapours through the pores of the earth.

It is generally obferved, that *peftilential difeafes* feize firft the cattle; which is not wonderful, fince they naturally carry their nofes near the ground, and fuck in the vapours as they rife, or feed on the herbage that is infected by them. It often happens, that the vapours do not rife fo high as to affect men at all; but tho' in this cafe the plague would be naturally confined to the cattle alone, yet it gets among men by means of the food eaten by them, and before tainted with the contagion. There is no doubt but that the flefh of animals that die of difeafes, partakes fomewhat of the nature of thefe difeafes; and when they are *peftilential*, may fpread a peftilence among us, which, perhaps, would otherwife never have reached us.

The plague once begun, frequently joins itfelf with fuch other difeafes as the people it attacks are moft fubject to; hence, in the northern nations, where the fcurvy is frequent, it is often feen that the plague and fcurvy appear mixed. Thefe two difeafes, in their nature fomewhat agreeing, make each other the worfe and more violent; but, on the contrary, there are other difeafes, depending on fuch contrary caufes, that the plague, if the patient furvives, proves a cure to them.

Dr. Hodges inftances the confumption, and the king's evil, as two difeafes of this kind; which, tho' in themfelves of the moft terrible kind, and when in an advanced ftage ufually baffling all remedies, yet he faw perfons in the plague that laft raged in London, cured of both by the plague: the fymptoms of the difeafe appearing more mild in thefe than in other cafes, and the patients at once recovering of both complaints.

He alfo tells us of fome people terribly afflicted with the gout for many years; who being at that time affected by the contagion, had the plague with lefs violent fymptoms than others; and were, on its going off, cured of the gout alfo.

A fever is ufually a concomitant fymptom of the plague, but it is not an infeparable fign of it. A palpitation of the heart is another of the ufual, but not conftant fymptoms; where this comes on, it is ufually very violent, and often is fo loud, that it may be heard at a confiderable diftance.

The plague is lefs contagious than is ufually fuppofed, and thofe who efcape the terror of it, often efcape it wholly. Hodges gives us an inftance of a poor woman who had the plague foon after her delivery, and fuckled her young child as fhe lay ill of it. She had a carbuncle on her breaft near the nipple which the child fucked at, and yet the mother recovered, and the child never caught the infection at all; tho' this feemed a circumftance under which there could be no efcaping.

Hodges, treating of the prognoftics of an imminent plague, tells us, that one very remarkable one is the change of chronic diftempers in general into acute ones, and thofe attended with very violent fymptoms; and a murrain among the cattle happening at the fame time, form together a prognoftic not eafily to be got over, without the terrible fequel of a general *peftilence*.

If the plague is very terrible at its firft appearance, it never is of long duration; and on the contrary, when it comes, from a fcarce perceptible beginning, more and more violent, it is generally of a long continuance. What time it takes from the beginning to the height, the fame it takes from the height to the final period.

The moft fatal fymptoms in the laft plague in London, and which ufually prefaged death very near, were hæmorrhages from the nofe or ears, fluxes of the menftrua in women, diarrhœas, dyfenteries, and greennefs and blacknefs of the excrements.

The firft fweats coming on without giving eafe, and long naufeoufnefs continuing afterwards, are alfo terrible fymptoms. The pulfe and urine, which are the two great things to judge by in moft illneffes, in thefe prefage nothing at all. The pulfe is fallacious in the higheft degree, and the urine often appears as well in the height of the plague, as while the perfon was in health.

Among the feveral prefervatives for particular places, the two beft are the burning fweet-fcented woods in the time, and fome of the refins, fuch as frankinfence and the like; the other is the firing a number of cannon every morning and evening. *Hodges* de Peft.

PETAL, among botanifts, that part of the flower which conftitutes the corolla: it generally diftinguifhes itfelf by its fingular colour.

When the corolla confifts only of one *petal*, its lower tubular part is called the *tube*; its upper expanded part, the *limb*: when feveral *petals* go to make up the flower, the narrow part where they are inferted is called *unguis*; their broader part towards the end, *bractea*. See COROLLA.

PETARDEER, in the military art, is he who loads, fixes, and fires the *petard*.

PETASITES, *butterburr*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the flofculous kind, being compofed of many fmall flofcules, divided into feveral fegments at their edges, and placed on the embryo fruit, and all furrounded by a fort of a cylindric cup, divided into many fegments. The feeds, when ripe, are winged with down, and the flowers of this plant appear before the leaves, early in the fpring.

The fpecies of *petafites*, enumerated by Mr. Tournefort, are thefe: 1. The great or common *petafites*. 2. The leffer *petafites*, with white flowers and angular leaves. 3. The fmall *petafites*, with colt's-foot leaves. 4. The leffer Alpine *petafites*, with fmall angular leaves. *Tourn.* Inft. p. 450.

The common *butterburr* is famous as a cordial and alexipharmic. It has been made an ingredient in moft of the compound medicines of that intention. The plague-water of the old

old difpenfatories owed the greateft part of its virtues to it. The root is the part principally ufed; and befide thefe virtues, it has thofe of an aperient and detergent. It is prefcribed in fuppreffions of the urine and menfes, and in coughs, afthmas, and other difeafes of the breaft. See BUTTERBURR.

PETASUS, among the Romans, a covering for the head, not unlike our hats; it had a broad brim, and was ufed in journeys to fave the face from being fun-burnt.

The *pileus* differed from the *petafus*, as having no brim *Pitifc.* in voc. See PILEUS.

The *petafus* is obferved upon the head of antient figures of Mercury; who wore it in the quality of the god of travellers and merchants. *Calmet.* Dict. Bibl.

PETECHIAL *fever*. See *catarrhal* FEVER.

PETELMA, in the Turkifh military orders, is the procurator general of the effects of the janizaries. When any one dies under the protection of this body, he feals up their houfes, to fecure the tenth part of their effects; which are due to the janizaries. *Pocock's* Egypt, p. 168.

PETIA, a word ufed by medical writers in different fenfes. It is commonly underftood to mean a piece of rag, ufed to tie up medicinal ingredients in, to be ufed by infufion in liquors; but *petia oculi* fignifies an hæmorrhage of the eye.

PETICULÆ, the fame as *petechiæ*, purple fpots appearing on the flefh in malignant fevers.

PETIGO, a word ufed by fome authors for *impetigo*. See the articlee IMPETIGO, *Cycl.*

PETILIUS-*flos*, a name ufed by fome botanical authors for the African marygold. *Ger.* Emac. Ind. 2.

PETIMBUABA, in ichthyography, the name of a fifh caught in the American feas, and called by fome, in Englifh, the *tobacco-pipe fifh*; a name more commonly ufed for the *acus ariftotelis*. See Tab of Fifhes, N°. 40.

It grows to the length of three or four feet; its body is like that of an eel, long and flender; and its mouth without teeth. The length of the nofe is confiderable, and the upper jaw is fhorter than the lower. Its eyes are remarkably large, not fmaller than a hazel nut, and fomething of the fame figure. Its fkin is fmooth, like that of the eel, and of a liver-colour on the back and fides, with feveral rows of blue fpots difpofed in three rows on the back, two on the head and one on each fide; there are alfo fome green fpots every where interfperfed among the blue ones. The belly is white, but has fomething of a brownifh red caft, and is flat. It is a well-tafted fifh. *Willughby's* Hift. Pifc. p. 234.

PETIOLATE-*leaf*, among botanifts. See LEAF.

PETIOLE, *petiolum*, among botanifts, expreffes that ftalk which fupports the leaves of a plant, as the peduncle does the fructifications.

Some ufe the word *petiolum* to denote the whole middle rib of a leaf of any plant, which is the ftrongeft part of it, and runs from the ftalk by which the leaf adheres to the tree or plant to its extremity, and from which the lateral fibres or nerves, as they are ufually called, commonly arife.

The authors who have written on the fubject of the anatomy of leaves, have had occafion to be accurate about the diftinctions of the feveral parts; and they have called this main or middle rib, the *petiolus*. The fide branches going off from this, they call *rami*; and the fubdivifions of thefe into more minute fibres *furculi*: thefe generally are interwoven into a reticular plexus one with another, and make up the fubftance of the leaf, with the bladders of a liquid matter, which are contained in their interftices.

All thefe folid parts of leaves, the *furculi* and *rami*, as well as the *petiolus*, are congeries of oblong fibres extended evenly together, and collected into one body; and the fibres in all parts of plants are divided into two kinds; the one containing juices, and called *fucciferæ*; the other giving paffage only to air, and therefore called *tracheæ*.

Lewenhoek has diftinguifhed the fucciferous veffels into two kinds, which he calls veins and arteries: the latter, he obferves, receive the fap from the root, where it is firft collected, and carry it up to the reft of the plant, and the others bring it back again from thence, in the manner of veins. Perrault has joined a great number of experiments to Lewenhoek's, in order to prove this fyftem of the juice veffels, but Fontenelle, and fome others, have doubted either the exiftence, or at leaft the ufe of the *tracheæ* or air veffels, fuppofing them either imaginary veffels, or deftined for other purpofes. The vine branches, however, examined either by a microfcope, or by a good eye in a good light, will fhew evidently that fuch veffels exift, and that in very great numbers: and the veffels in the *petiole* and *furculi* of leaves, when ftrictly examined, are found to be of both thefe kinds. Act. Erudit. 1722. See TRACHEÆ.

PETIOLUS, a word ufed by botanical writers to exprefs the ftalk of a fruit.

PETIVERIA, in botany, the name of a genus of plants, the characters of which are thefe: The perianthium is compofed of three flender, erect, obtufely-pointed leaves, and remains to inclofe the feeds. There are no petals; the ftamina are fix fubulated equal erect filaments, of the length of the cup; the antheræ are fimple; the germen of the piftil is oblong, and of a compreffed figure; the ftyles are four, they are fubulated and ftrait; the ftigmata are fimple and permanent; the feed is fingle, of an oblong figure, narrow at the bottom, broader at the top, emarginated and crowned with the ftyles, which are rigid, acute, and fomewhat bent. *Linnæi* Gen. Plant, p. 150. *Plumier*, Gen 39

PETOLIN, in natural hiftory, the French name for a fhrub of the piftachia kind, famous for affording bladders or tubercles on its leaves and tender branches, in the manner of the common turpentine-tree; which are found full of infects. Thefe infects are always found to be of the puceron kind, and fome of them are winged, others not, as is known to be the cafe in that genus of animals. Thefe bladders, and thofe of the turpentine-tree, called its *horns*, have been by fome fuppofed to be the natural production of the trees, but they are in reality only a peculiar fpecies of bladder-galls, formed by thefe animals, one female of which making her way into the leaf, while the young raifes its covering membrane into a bladder, in which fhe produces her young ones; which by fucking its fides, derive the juices to it, and occafion its increafe. *Reaumur's* Hift. of Inf. p. 34. See the article PUCERON.

PETRÆA, in botany, a name given by Houfton to a genus of plants, in honour of the name of the Lord Petre. This author, however, was guilty of an error in the characters of this genus; for he defcribed the flower of this, and the fruit of another very different genus, the *tetracera*. The external refemblance of thefe two trees led him into the error; but Linnæus has given its characters more fully, and without any fuch miftake. They are thefe: The perianthium is very large and coloured; it is compofed of one leaf divided into five obtufe expanded fegments, and remains with the fruit. The flower confifts of one leaf, and is irregular and fmaller than the cup; its tube is very fhort; its verge plain, and divided into five fegments, which are roundifh; and the loweft of which is larger than the others. The ftamina are four filaments, two being longer than the others, and all hid in the tube of the flower. The antheræ are fimple; the germen of the piftil is of an oval figure; the ftyle is fimple, and of the length of the ftamina; and the ftigmata is obtufe. The error of Houfton, in regard to the fruit, has left the world wholly in the dark as to what it really is. *Linnæi* Gen. Pl. p. 298. *Houft.* Act.

PETRIFACTIONS (*Cycl.*)—The knowledge of this part of natural hiftory is but of very late years arrived at any degree of perfection. Dr. Hook, Steno, Boerhaave, and Auguftino Scilla, have been among the firft who treated judicioufly of thefe things; but great honour is to be done to Fabius Columena, who, before the time of any of them, publifhed two admirable difcoveries upon the parts of aquatic and terreftrial animals, and of plants buried in the earth, and which he had himfelf feen dug up in the mountains of Andria, Apulia, and other places. He boldly declares, that thefe could be depofited there by no other means but by the general deluge in the days of Noah; and enters into the reafons why, in fome places, thefe remains of animal and vegetable bodies are found perfect and intire, and in others corrupted or altered; and obferves, that they anfwer fo exactly in every lineament to the recent bodies of the fame kind, that there can be no doubt of their having once been alfo fuch.

It is a very remarkable obfervation, in regard to the really and certainly determining the origin of *petrified* fhells, that they are not all alike altered by lying in the earth, but that they differ according to the matter among which they have lain to *petrify*. Thus the fame fpecies of fhell *petrifyed* in a loofe fand-ftone, is never nearly fo hard as when *petrifyed* in a folid quarry, or in a hard lime-ftone; fo that it is evident they were brought into the places where they now lie, in the ftate of fhells; and that the ftone in which they are depofited, having imparted to them its own nature, they are harder or fofter, in proportion to its hardnefs. We find in pits where the fhells are depofited in loofe earth, that they are often not *petrifyed* at all, but rendered more foft and crumbly than before.

The echini marini, and other fuch hollow and open-mouthed fhells, are very often found filled up with earth or ftone, the fame with that in which they lie; and refufe matter is fometimes found among this, fuch as the fragments of other fhells, and the fpines of fome other echini. All thefe ferve to prove that the fhell, in its recent ftate, was fufpended in water among fuch fubftances as thefe. And it is not to be fuppofed, with fome authors, that they are found originally as foffils within the fhell; fince, in this cafe, they would be fometimes doubtlefs found of fuch a fize as could not have got in at the mouth of the living animal; but this is never the cafe And upon the whole it appears very plain, that after the membranes which covered the mouths of thefe fhells in their recent ftate, were decayed or wafhed away, thefe extraneous bodies found entrance at them along with the marle, chalk, ftone, or whatever other fubftance

ſubſtance they were among, which was evidently all ſoft and fluid at that time. *Auguſtino Scil'a* de Petrifact.

The *petrified* vertebræ of fiſhes cannot be ſuppoſed real foſſile productions, but are plainly remains of animals; and when examined ever ſo accurately, they are found to agree with the ſame bones in the recent animal in every lineament Scilla mentions a foſſile lobſter's claw preſerved in his muſæum, and found in the hills near Meſſina, in which a piece of a ſcallop-ſhell was found clenched juſt in the manner in which that animal ſeizes its prey. Thoſe who ſuppoſe theſe foſſiles to be really produced in the earth, ſurely cannot ſuppoſe that there could be any ſeminal principle only for the claw of an animal. In Poland there is a kind of ſtone called *niec kammi*, which they bring from a place called by the ſame name. This ſtone has very much the appearance of the grain of wood, and is probably wood *petrified*. Rzaczinſki, in his hiſtory of Poland, mentions the place, and tells us, that there are many whole roots and parts of the trunks of trees *petrified* there. He tells us alſo of an old beech tree in Podolia, whoſe lower part is not only *petrified*, but that into the hardeſt and pureſt of the common ſtones; it being converted wholly into flint, and ſerving the country people thereabout for their common uſes as ſuch. The author tells us, indeed, that the lower parts of trees become *petrified* there as they ſtand, and while the upper parts continue growing; but this ſeems ſcarce credible.

We have indeed ſome other accounts of the ſame nature, but not from authors of ſufficient authority to build our faith on, in ſo ſeemingly unnatural a caſe. This author, in particular, ſeems too credulous in many inſtances; among other things, giving us an account of ſome earthen veſſels found at conſiderable depths in the earth, which he ſuppoſes to have been formed there by nature. We have other accounts beſide this of foſſile urns, but the authors of them all have either miſtaken the cruſtated ferrugineous bodies for urns, or elſe they have ſuppoſed things natural which are certainly artificial. *Rzaczinſki's*, Hiſt. Polon.

Mr. Boyle mentions a kind of ſandy earth found in England, which turns wood into ſtone, tho' there be no *petrifying* ſpring near the place: and this, he ſays, is done in a better manner than by any water he ever ſaw. See Works Abr. Vol. I. p. 161.

Animal PETRIFACTIONS, a term uſed to expreſs ſuch *petrifactions* as are found in the ſeveral parts of the bodies of living creatures.

Of theſe the human body affords many which are the occaſions of very terrible and generally incurable diſeaſes. The philoſophical tranſactions afford us two very ſingular inſtances of this ſort of *petrifactions*; the one in a woman, whoſe whole left kidney was intirely *petrified*, not being filled up in its cavity with a ſtony concretion, as frequently happens in nephritic caſes, but its whole ſubſtance converted into abſolute ſtone, only covered with a thin ſkin.

The other inſtance is in the caſe of a conſumptive perſon, whoſe lungs were found, on diſſection, full of ulcers, and thoſe having almoſt all of them, more or leſs gravel in them; but this was not all, for ſeveral large pieces of the lungs were found, as the kidney in the other inſtance, wholly concreted into ſtone, only covered with a thin ſkin. Phil. Tranſ. Nº 71.

PETRIFACTIONS *of Lough Neagh*. The moſt noted place for *petrifactions* in our dominions is, the famous lake called *Lough Neagh*, in Ireland. Moſt of the antient writers who have given accounts of Ireland, have mentioned the power the waters of this lake have of turning wood into ſtone; and ſome of them have added the abſurd to the marvellous, by affirming, that it would turn that part of the wood which was buried in the mud into iron, that part that was in the water into ſtone, while the part which was above water remained mere wood ſtill.

Some late authors, as Molyneux Nevil, Smyth, Woodward, and others, ſuppoſe this effect not to be found in the water of this lake, but that it either is in the earth about the lake, or elſe that the *petrifactions* found there are not ſuch as have been formed there, but *petrified* elſewhere, and long ſince, and brought thither by the waters of the deluge.

Mr. Smyth affirms, that no experiment ever made has proved that the water of that lake has any power of *petrifying* wood; and gives an example of a gentleman's having planted two ſtakes of holly in the lake, on purpoſe to try; which were taken up after 19 years, without the leaſt advance made toward *petrifaction* It is certain, indeed, that vaſt quantities of *petrified* wood are found in the lake, and even whole trees with their roots and branches all turned to ſtone, have been found buried in the mud of it; and it ſhould ſeem the moſt rational account of their being found there, that they had grown in their natural ſtate on the banks of the lake, and had, in fine, fallen in, and been there *petrified*. And it is equally certain, that of the great quantity of wood met with here, the different pieces are in different degrees of *petrifaction*; and that ſeveral of them are ſeen to be *petrified* in different degrees in their parts; nay, that one ſide of a large piece is often ſeen to be mere rotten wood, while the other is hard ſtone.

It is not to be aſſerted, becauſe ſtakes driven down in ſome one part of the lake are not *petrified* in a ſmall number of years, that therefore the water has no where a *petrifying* virtue; ſince it is poſſible that there may be ſprings ariſing in ſome parts of it, the waters of which may be ſo highly impregnated with ſtony matter, as to *petrify* wood, if they meet with it near their origin; yet the waters of theſe, when mixt with that vaſt body of water which makes the whole lake, may not be able to communicate that *petrifying* quality to ſo large a quantity.

There is ſcarce any water that does not contain ſaline and ſtony particles, which may be ſeparated from it by evaporation; and the generality of *petrifying* ſprings, when examined by this proceſs, are found to be very full of calcarious, or other ſtony matter, and frequently of ferrugineous and vitriolic kinds. Thoſe which contain calcarious matter, when they drop upon ſticks, moſſes, or other vegetable bodies, act on them by incruſtation; their calcarious particles being left behind while the water goes off, and forming by this means ſucceſſive cruſts ſometimes to a great number, which adhere cloſely to one another, and form a ſtony coat to the wood: if theſe be broken at different periods of time from their formation, ſome of them will be found with the wood remaining ſound within them, others with the wood rotten; and others with a ſtony matter of the ſhape of the wood, ſupplying its place, and formed by the depoſition of ſtony particles in the cavity left by the periſhed wood. Sometimes, indeed, theſe waters permeating the pores of wood, fill them up with the calcarious particles they leave behind them; and when the vegetable matter is periſhed, the calcarious concretion remains in its place and exact ſhape. The bodies in this laſt ſtate approach much more to the nature of *petrifactions* than the others, but they all differ greatly from the genuine *petrifactions*; becauſe it is not true ſtone that they conſiſt of, but merely a ſpar or calcarious matter, which readily ferments with, and is ſoluble in acids, and by a ſlight calcination is reduced to lime, in the manner of other ſpars.

The *petrifying* waters, which contain particles of true and genuine hard ſtone, and perhaps with them ſome ferrugineous or other metallic ones, do not act in this manner by incruſtation, but always leave the ſurface naked, and penetrate into the inner ſubſtance of the wood, filling every pore with the hard matter they depoſit; which, in fine, without altering their texture or ſize, adds greatly to their gravity, and gives them the hardneſs of a ſtone. In many parts of Ireland there are great quantities of the incruſtations of calcarious matter on vegetables; but the *petrified* wood found in the Lough Neagh, and on its ſhores, is wholly of the other kind; and ſhews no covering of any foreign matter, but preſerves the grain and all the veſtigia of wood; all the alteration is in the weight and cloſeneſs reſulting from the ſtony matter having filled all the pores: theſe make no efferveſcence with acids, nor will be calcined into lime in a common fire, as the calcarious incruſtations are.

It is probable, that the *petrifying* matter with which the water of ſome part of this lake is endued, is owing to ſeveral ſprings; which running in their courſe thro' mountains where there is abundance of ſtony and mineral matter, waſh off and carry with them great quantity of the particles of one or both theſe ſubſtances; which they afterwards depoſit in the wood they meet with, where they are diſcharged up thro' the mud of this lake; and that tho', when blended among the general water of the lake, they have not this property, yet if the ſtakes of holly had been driven down juſt where thoſe ſprings were, they would probably have been *petrified*, tho' there was no ſuch quality in the reſt of the water of the lake And that there are theſe ſprings in ſeveral parts of the lake, is certain from hence, that when in the great froſt in the year 1740, the great lake in general was frozen over ſo as to bear men on horſeback, yet ſeveral circular ſpaces remained unfrozen.

The *petrified* wood is found in conſiderable plenty on the ſhores of the Lough, but moſt abundantly after ſtorms; and this rolling about of the *petrifactions* at the bottom in ſtorms, makes it not eaſy to fix upon the place where they received their alteration.

Nor are the *petrifactions* found only in and about the lake, but they are turned up by the plough almoſt daily in all places, at two or three miles diſtance from it; and ſome have believed that they were all *lapides ſui generis*, and never had been wood till the roots of trees were found in their natural poſition in the ground, with their ſmaller ramifications and every other part wholly *petrified*.

Many of theſe are much ſofter than the *petrifactions* in the lake, and may be cut and cleaned with a knife, tho' not near ſo eaſily as other wood. It is not impoſſible, but that many of theſe may have been originally *petrified* in the lake, which may have either once extended over a much larger ſpace of ground than it now does, or elſe have loſt on one ſide what it has gained on the other; not that it is neceſſary to ſuppoſe this, ſince there is no doubt but that mineral ſteams and exhalations being highly ſated with ſtony particles, are often found to have a *petrifying* virtue; and ſuch effluvia ariſing thro' the earth may operate on wood accidentally buried in

in that ground; and this seems to be the most probable opinion as to the origin of the *petrifactions*, not only of our fields, but of those found in many parts of the world among sand or gravel.

It is to be observed also, that the finer the lapidific particles are, the more beautiful and natural the *petrifaction* will appear. Of this kind there was once found a beautiful specimen on the shores of the Lough Neagh. This was a root of the common yellow flag-flower, with the bottom part wholly converted into stone, but yet retaining all the fibres, and every part of the texture of the root; the pith in the middle was turned into a whiter stony substance, and the upper surface had all the traces of the several tubercles, or first shoots of leaves, tho' a very hard stone; and the outer covering of some of these retained its vegetable nature still so far, as to be flexile in a small degree, while all within was solid stone.

Some of the pieces of *petrified* wood, found on the shores of the lake, have curious veins of a red and bluish colour, and others are beautifully variegated with black and white striæ. The woody part of them gives a red tincture to aqua fortis, and when taken out of that menstruum, shews some red spots in its pores, which, perhaps, are its first approaches towards *petrifaction*, and are either of a mineral or stony matter.

It is common to find in the cracks of these stones, nay, and of such parts of them as are yet wood and not turned into stone, great numbers of very beautiful and regular, tho' small, crystals: these are transparent and hexangular, and of the same kind with the small crystals found in the cracks of ferrugineous stones, and within our common flints. When calcined, the powder yields to the magnet, which shews that they have some ferrugineous as well as stony particles: and it is not unfrequent to meet with pieces of unaltered wood in the very center of the largest of these *petrified* masses; and the *petrified* parts of the masses, when examined by the microscope, appear extremely beautiful, their pores being all visibly filled with pure and very bright crystal. The different degrees of *petrifaction* appear very various in the several pieces, some are woody on the outside, and altogether stony within; and others outwardly stony, and inwardly unaltered wood; and others having the woody or the stony part appearing only in thin lines and coats on different parts. The harder or more stony parts of these *petrifactions* always give fire with steel. Phil. Tranf. N°. 481.

Some of them shew the grain of ash, some of holly, and some of fir, others of oak; but these are more rare. They frequently have the plain traces of knots and other irregularities, and some are found bent and half broken, and plainly have been worked by art before they were *petrified*.

It is a common opinion, that these stones are what are used for hones in different parts of England; but this is an error, the substance of which these are made being real stone, and not found here, but at Drogheda. Those *petrifactions* of the lake, which have part wood, part stone, usually lose the wood afterwards, by its cracking and falling to pieces as the stone dries; but if examined while it remains on the stone, it is very convincing, as to the reality of the origin of the whole from wood. Id. ibid.

PETRIFICATION, in medicine. See ANCUBITUS.

PETRIFIED *Ivy*. See the article IVY.

PETRIFYING *waters* Alonso Barba gives an account of some *petrifying* waters of Peru, which greatly exceed all those we have in Europe in the quantity of stony matter they contain. He tells us, that they soon choak up their own passage by the stony matter they deposit there; and that all the cattle that drink of them die. He adds another story, which he probably took a little too hastily upon credit, which is, that they have moulds of the shape of our bricks, which they fill with this water, and that on being exposed to the sun a few days, the water is wholly converted into a stone of the same shape; and that they build their houses and other buildings with these stones. *Alonso Barba* de Metal.

PETROCOSSYPHUS, in zoology, a name given by some authors to the bird more usually called from its colour the *cæruleus*.

It lives among the rocks, in woody mountains, and sings very sweetly. See CÆRULEUS.

PETROL, or PETROLEUM—(*Cycl.*)

Mr. Boulduc made several experiments with the white *petroleum* of Modena, an account of which he gave to the Paris academy.

It easily took fire on being brought near a candle, and that without immediately touching the flame; and when heated in any vessel, it will attract the flame of a candle, tho' placed at a great height above the vessel, and the vapour it sends up taking fire, the flame will be communicated to the vessel of heated liquor, and the whole will be consumed. It burns in the water, and when mixed with any liquor swims on the surface of it, even of the highest rectified spirit of wine, which is $\frac{1}{7}$ heavier than pure *petroleum*. It readily mixes with all the essential oils of vegetables, as oil of lavender, turpentine, and the rest, and seems very much of their nature: nor is this very strange, since the alliance between these bodies is probably nearer than is imagined, as the essential oils of vegetables may have been originally mineral ones, and drawn up out of the earth into the vessels of the plant. Mem. Acad. Par. 1715.

Petroleum, when shaken, yields a few bubbles; but they sooner subside than in almost any other liquor, and the liquor resumes its clear state again almost immediately. This seems owing to the air in this fluid being very equally distributed to all its parts, and the liquor being composed of particles very evenly and nicely arranged.

The extensibility of this oil is also amazing. A drop of it will spread over several feet of water, and in this condition it gives a great variety of colours, that is, the several parts of which this thin film is composed, act as so many prisms. The most severe frost never congeals *petroleum* into ice, and paper wetted with it becomes transparent, as when wetted with oil; but it does not continue so, the paper becoming opake again in a few minutes, as the oil dries away.

Spirit of wine, which is the great dissolvent of sulphur, has no effect upon *petroleum*, not even with ever so long a digestion. It will not take fire with the dephlegmated acid spirits, as oil of cloves, and other of the vegetable essential oils do: and in distillation, either by balneum mariæ, or in sand, it will neither yield phlegm nor acid spirit; but the oil itself rises in its own form, leaving in the retort only a little matter, thick as honey, and of a brownish colour. Whoever, therefore, would use this oil in medicine, must take it as nature has prepared it, art having no power to make any alteration in it. Mem. Acad. Paris 1715.

Alonso Barba, in his book of metals, gives a very melancholy instance of the power of *petroleum* of taking fire at a distance: he tells us, that a certain well, yielding *petroleum* on the surface of its water, being to be repaired, the workman took down into the well with him a lanthorn and a candle in it; there were some holes in the lanthorn, through which the *petroleum*, at a considerable distance, sucked out the flame of the candle, and taking fire, burst up with the noise of a cannon, and tore the man to pieces. *Alons. Barba* de Met.

The people of mount Ciaro, in Italy, have some years since found out a much easier way of finding *petroleum*, than that they formerly had been used to.

This mountain abounds with a sort of greyish salt, which lies in large horizontal beds, mingled with strata of clay, and large quantities of a spar of that kind called by the Germans *selenites*; which is the common sort, that ferments with acids, and readily dissolves in them, and calcines in a small fire. They pierce these slates in a perpendicular direction till they find water, and the *petroleum* which had been dispersed among the cracks of those slates, is then washed out by the water, and brought from all the neighbouring places to the hole or well which they have dug, on the surface of the water of which it swims after eight or ten days. When there is enough of it got together, they lade it from the top of the water with brass basons, and it is then easily separated from what little water is taken up with it. It is remarkable, that all the *petroleum* got by this means is white, whereas that of Modena is yellow, and that of Parma brown. These wells or holes continue to furnish the oil in different quantities for a considerable time, and when they will yield no more, they pierce the slates in some other place. Mem. Acad. Scien. Par. 1736. See the article NAPHTHA.

Petroleum is never used among us; but the French give it internally in hysteric complaints, and to their children for worms: some also give it from ten to fifteen drops in wine, for suppressions of the menses. This, however, is rather the practice of the common people than of the faculty.

PETROMARULA, in botany, a name given by several authors to the pyramidal rapunculus of the island of Crete, called by Mr. Tournefort, *rapunculus creticus seu pyramidalis alter*. See RAPUNCULUS.

PETROMYZON, the *stone-sucker*, in the Linnæan system of zoology, the name of a genus of fishes of the chondropterygii order, comprehending the lamprey, &c. The characters of this are, that the apertures of the branchiæ are seven on each side. *Linnæi* System. Natur. p. 52

The name is originally Greek, and is derived from the words πέτρα, a stone, and μύζω, to suck; this fish being usually found in rivers adhering to the stones by sucking, and so keeping its place.

The characters of this genus, according to Artedi, are these: the foramina, or apertures of the branchiæ, or lungs, are seven on each side; they are placed longitudinally, and beside these, there is one single aperture in the head, placed immediately between the eyes. The body is long, and nearly of a cylindric figure; it is smooth, and has only two fins, and those are both placed on the back.

The species of this genus, enumerated by Artedi, are these: 1. The *petromyzon*, with only one row of minute teeth in the verge of the mouth, except the large lower ones. This is the *lampetra fluviatilis minor* of authors, or the lampern eel: and the *lampetræ medium genus*, called by the Germans the *brick*, is only a variety of this, not a distinct species. 2. The spotted *petromyzon*, with about twenty rows of teeth. This is the *lampetra major* of authors, and is called in English the *lamprey*. 3. The *petromyzon* with an annulated body, and with two appendages on each side of the mouth. This is the *enneophthalmus cæcus* of au-

authors. The body consists of eighty-four rings, and it has no teeth. *Arted.* Gen Pisc. 42.

PETRONELLUS, in zoology, a name under which some have described the bunting.

PETRONIA *marina*, in zoology, the name of a small bird of the œnanthe kind, or nearly allied to that genus. Its beak is strong and sharp, like that of the chaffinch; its head is of a brownish grey, but has usually a long whitish streak running along it; its neck is ash-coloured, and at the bottom is variegated with black; the rump is of a brownish green; the long wing-feathers are blackish, with edges and tips of green, and are white underneath; the breast is of a dusky white, and the tail brownish, variegated with yellow. It is, however, distinguished from all other birds by a fine large yellow spot, which it has on the middle of its throat. *Aldrovand.* de Avib. l. 17. c. 38.

PETROSELENI *radix*, *parsley-root*. See PARSLEY.

PETROSELINUM *Macedonium*, in the materia medica, the name of a seed used in medicine The plant which produces it is a native of the warm countries; and the seed should be chosen for use clean, well fed, longish, and of a brownish green colour, and well tasted, and aromatic. The buyer should be careful in the choice of this seed, because it is commonly adulterated, and the seeds of the common *parsley*, or those of a sort of smallage, are too frequently sold in its place. It is aperitive, provokes urine and the menses, and expells wind; and, in form of a cataplasm, is said extremely to help the gout. It is an ingredient also in the Venice treacle. *Lem.* Dict. of Drugs.

PETROSUM *sal*, in natural history, a name given by some of the old writers to the nitre of Ægypt, used in the antient times; and by others to the common nitre, which we use at present, and call by a similar name, *salt petre*.

PETTY *bag* (*Cycl.*)—In antient times the chancellor was likewise chaplain to the king, and it was his business, in the time of the justiciar, to write the diplomata; that is, all charters and commissions from the king: therefore, when the power of the justiciar was broke, he obtained the *officina brevium* and *chartarum regiorum*; from thence all the extraordinary jurisdictions, touching granting of charters, as likewise all inquests of office to entitle the crown, were returned into this office; and the exchequer, in which these things were antiently transacted, became only an ordinary court of revenue, to let leases to the king's farmers, and to get in the king's debts: and therefore the office in the exchequer was only an office of instruction, of what lands were in the king in particular counties; but to invest lands in the crown *de novo*, it was necessary to have an office under the great seal, and so to grant lands from the crown, unless it were merely farms granted for years. Vid. New Abr. Law, Vol. I. p. 587.

From hence, at this day this court has a jurisdiction to hold plea upon a *scire facias*, to repeal the king's letters patents upon petitions, *monstrans de droit*, traverses of offices, *scire facias* upon recognizances, executions upon statutes, &c. which being registred in this court, the process thereupon issues, and is returnable there, and entered in the office called the *petty bag*; whereas the writs which were the foundation of the business of the other courts, were put together in the hamper, which gave the distinction of those names, and begat distinct officers in the court. 4 Inst. 80.

If in this court the parties descend to issue, the chancellor cannot try it, but is to deliver the record, with his proper hand, into the king's-bench, where judgment is to be given; but upon a demurrer, the chancellor is to give judgment [a]: so if the issue is to be tried otherwise than by a jury, as by the bishop's certificate, judgment shall be given in chancery [b].

[a Vid. New Abr. Law, Vol I. p. 587. b 1 Jon. 80.]

Also all personal actions, by or against any officer or minister of this court, in respect of their service or attendance, may be determined in this court; but in these no jury process can issue, therefore the record is to be removed into the king's-bench, as before mentioned.

PETULANTIUM *festum*, in antiquity, a festival celebrated by the Athenians and Lacedæmonians in honour of the moon, under the name of Venus: at which the men assisted, dressed in womens cloaths; and the women in the habits of men. *Hoff.* Lex univ. in voc.

PETUNTSE, or as it is usually called *petunse*, one of the two earths or fossile substances of which the porcelain ware of China is made. The other is named *kao in.* See KAOLIN.

The *petuntse* is sprinkled all over with bright glittering particles. It is beaten to powder, and afterwards made up into a sort of bricks, and in that form it is sent to the places where it is to be wrought. It is of a hard texture, and of a somewhat greenish colour. Mr. Reaumur, of the academy of sciences of Paris, who was extremely industrious in searching into the nature of porcelain, obtained some specimens of the *petuntse*, both in its native state, and in form of the brick, which is given it after it is powdered and reduced to a paste.

Mr. Reaumur found that the *petuntse* is so far from being an earth, as usually supposed, that it was truly of the nature of the European flint or pebble, as he establishes the character of that body but to understand this rightly, it is to be observed, that this author makes the flints and pebbles a very large class of bodies, some of which are more, some less transparent; and that this *petuntse* is of the nature of the coarser, or less transparent kind, the surface of which, when broken, is not so smooth and polished as that of the ordinary flint. The great character of these stones for the porcelain manufactures is, however, that they are very easily vitrified, without the assistance of any salt, and without the immediate contact of the fire, the operation succeeding in a crucible, which is not at all the case in regard to the European flints, they very differently melting alone in a crucible, and then only into a whitish opake glass.

It being certain from hence, that one of the two ingredients of the china-ware is easily vitrifiable, it follows, from the experiment of the whole mixture, or china-ware not being reducible into glass in a large fire, that it is a composition of a vitrifiable, and a not vitrifiable (or at least not easily vitrifiable) substance; and consequently, that the kaolin is a scarce vitrifiable body, and that the result of the action of fire on a mixture of these two, is a semivitrification; which is what we call the china-ware.

If we, therefore, could, in Europe, provide the materials of china, or such as were like them, we might reasonably hope to succeed; and this appears far from improbable. The *petuntse* is easily supplied by many of our own earths, stones, and sands, as nothing is required in it more than a property of running easily into a white glass. The kaolin seems most to be resembled by our European talcs. Mem Acad. Par. 1727. See the article KAOLIN.

PEUCEDANUM, *hogs-fennel*, in botany, the name of a genus of plants, the characters of which are these: the flowers stand in umbells, and are of the rosaceous kinds, being composed of several petals arranged in a circular form, and placed upon a cup, which afterwards becomes a fruit, composed of two flat, oval, marginated, and striated seeds. To this it is to be added, that the leaves are alated, narrow, grassy, and divided always into three parts.

The species of *peucedanum*, enumerated by Mr. Tournefort, are these: 1. The greater Italian *peucedanum*. 2. The smaller or German *peucedanum*. 3. The French *peucedanum*, with fewer and shorter leaves. And, 4. The French *peucedanum*, with fewer and shorter leaves, with purple flowers. *Tourn.* Inst. p. 318.

The common *hogs fennel* is found in wet and moorish places, and about fen ditches. It flowers in June and July. Its root is esteemed of great use, as an expectorant and attenuant. It is prescribed in diseases of the breast and lungs, particularly in those in which those parts are loaded with a tough phlegm. It is also recommended in all obstructions of the viscera. It promotes urine, and is recommended in nephritic cases. The old authors have spoke greatly of its efficacy in all nervous cases, and have recommended it as a singular remedy in lethargies, palsies, epilepsies, and the like.

PEWIT, in zoology, the English name of a common bird of the *larus*, or sea-gull kind, called by some authors *larus cinereus*, and by others *cepphus*, and in some of the counties of England the *black cap*, and *sea-crow*.

It is about the size of a pigeon Its beak is red; its head and throat of a greyish black, and its neck, tail, breast, and belly white; the middle of its back grey. It has its English name from its note, which seems to express the word *pewit*. It is affirmed by many, that the head of this bird is only black at a certain season of the year. *Ray's* Ornithol. p. 264.

PHACOIDES, a word used by the antient physicians to express any thing that in size and shape approached to a lentill. Thus the crystalline humor of the eye was so called.

PHACOPTISANA, a medicine often mentioned by the antient writers as a nourishing and strengthening thing: it was a ptisan with lentills.

PHACOSIS, a word used by the antients to express a disorder of the eye, appearing in form of a black spot, of the size and round figure of the lentill.

PHÆCASIA, in antiquity, a kind of shoes. For the different opinions concerning which, see *Hofm.* Lex. Univ. in voc.

PHAGEDENIC-*water*, a name given to lime water, to every pint of which twenty or thirty grains of sublimate has been added. It is a great deterger of foul wounds; whence it has its name.

PHAGESIA, φαγησια, in antiquity, a festival in honour of Bacchus, celebrated during the Dionysia. See DIONYSIA, *Cycl.* It was otherwise called *phagesiposia*, φαγησιποσια; which names come from φαγει, to eat, and πινειν, to drink; because it was a time of good chear. *Potter*, Archæl. Græc. l. 2. c. 20. T. 1. p. 434.

PHAGON, φαγων in antiquity, a festival of the same nature with that called *phagesia* See PHAGESIA.

PHAGRUS, the *sea bream*. The Artedian system of ichthyology does not allow this fish a peculiar generical name, but makes it a species of the large genus of the *spari*: the author distinguishes this from the others by the name of the *reddish sparus*, with the skin hollowed into a sinus at the roots of the back fins. See SPARUS.

PHAGUS, in botany, a name given by many authors to the exulus, or sweet and esculent oak, found in Greece and Dalmatia. *Parkins.* Theatr. p. 1387.

PHALACRA, a word used by Hippocrates to express all the blunt

blunt instruments used in surgery; such as probes and others, with buttons at the ends.

PHALACROCEPHALUS *indicus*, in zoology, the name of an anadromous fish of the East Indies. Its neck and head appear naked and bald, as it were It is all over of a greyish white in colour, and is variegated with red spots about the mouth. The eyes are large and very prominent, and their irises yellow. Its usual size is about a foot and a half in length, and it lives part of its time in the sea, and part in rivers. It is an extremely delicate-tasted fish, and esteemed one of the finest of that part of the world. It is called by the Dutch *kael kop*. *Ray*'s Ichthyogr. Append p. 2.

PHALAIA, a word invented by Basil Valentine, and used as the name of a *panacæa*, or universal medicine; but Rolfink has since used it to express a tincture of jalap.

PHALANGIUM, in the history of insects, the name of a peculiar genus of *spiders*, the characters of which are these: They do not move regularly and evenly as other *spiders*, but hop in the manner of fleas. This was a character recorded of them by Pliny, and the antients, and is found at this time in all species. They have a square forehead; and in this are placed eight eyes of different sizes, and disposed in form of a part of a circle. They have also the forelegs greatly longer and stronger than any of the others. Of these there are four principal kinds: 1. The grey *spider*, variegated on the belly, with six transverse fasciæ meeting in an angle in the middle. These are alternately black, and of a silvery white. It is of a middle size, and its grey colour seems a mixture of a deep black and a silvery white. It is common in woods and about old walls 2. The reddish brown *spider*, variegated with two large black marks, and a foliaceous obscure figure on the body. This is somewhat smaller than the former, and is found about old walls, but not frequently. 3. The yellowish *spider*, with green eyes, and with three yellow lines on the hips. This is of a middle size, but it is a very rare species. 4. The reddish rock *spider*. This is a moderately large kind, and is of a reddish chesnut colour. It is a very scarce *spider*, and lives among rocks and on heaths. *Ray*'s Hist. of Insects, p. 36. See OPILIO.

PHALANGIUM *apulum*, the *apulian phalangium*, a name given by authors to that large and poisonous species of spider called by the vulgar, the *tarantula*, from the name of a city of Calabria, Tarantum; near which it is very common. Valetta, a monk of Apulia, who had always resided about the places where this mischievous animal is most frequent, and had had many opportunities of tracing its several qualities, published a succinct, but very accurate history of it in the year 1706, under this name.

It had its name *phalangium*, from the three phalanges or joints of its legs, and this name equally suiting many other spiders, as well as this, it ceased to be its appropriated name, and was applied as a generical term to several other spiders of the larger kind; among which this species was always distinguished by the epithet *apulian*, from the place where it was so frequently found.

The *tarantula*, or *apulian phalangium*, is frequent in all parts of this country, in uncultivated places, but more especially it breeds most in sunny dry hills, and particularly in such parts of them as are exposed to the south. It is said not to be found any where, except in Apulia; but probably it is an inhabitant of many other places, tho' its poison may not be violent enough any where else to bring on the effects it does there: as we find in vipers and many other poisonous creatures, that the strength of their poison differs greatly in degree in different places. As this spider is very tender, and easily injured by cold winds and rain, it always digs itself a cave in the side of a hill for its habitation; and usually chuses for this purpose the hardest ground it can find, which is better able to defend it, and which it easily works into with its forceps and claws. This always is hollowed upward in the hill, and by that means is safe from wet, all the water in rainy seasons running down over its top. Sometimes it burrows itself a cave in a valley or plain, but then it always chuses a dry, usually a chalky soil. In this case the entrance into its cave is small, and within there are several winding passages: if it happens to be surprised with wet in this place from hard rains, it quits the floor and hangs by its feet against the top of the cave. It preys upon a number of small insects with which the fields of Apulia abound, and seldom appears in the day-time, but creeps out about the time of sun-set, and preys at large upon the animals which are then betaking themselves to rest; without the danger it would be exposed to from its own enemies by day light. If at any time he remains the whole evening in his cave or den, it is only to practise another method of hunting his prey In this case he comes forward to the mouth of the hole, and there lies in wait; his fore-legs are placed at the extremity of the hole, and his eyes have a clear view all round. The other insects are not aware of this trick, but as they walk near his hole he bursts out upon them, and seizing them, conveys them into his habitation; where, as soon as he has eaten them, he retires back into his cell to dispose of the wings and other fragments, till he can carry them out at a more convenient time, and then places himself in his former posture for another prey.

The peasants of Apulia have a method of getting him out of his hole in the day-time, in order to destroy him. This they do by making a soft hissing noise thro' an oat straw; whether it be that the creature loves this sound, or rather that he takes it for the voice of some insect that he is used to prey upon, he always comes out, and falls a sacrifice to his greedyness.

This creature has eight legs, and walks very well; his legs have each three joints, and are covered with a fine downy hairyness: they are of a whitish colour at the bottom, and variegated with black lines, and are wholly black in their upper part, where they are joined to the breast These all arise from a kind of oval shield, which is placed upon the breast, and is black, hairy, and very hard. This is called by some the *speculum* of the *tarantula*. From the shoulders there grow a pair of horns, at least they are usually called so, tho' they seem much better to deserve the name of *arms*. The use of these is to hold fast the prey, that it may not be able to escape while he is killing it with his forceps. These horns or arms have the same number of joints that the legs have, but they greatly differ from the legs, in that they are shorter and of a yellowish colour. They are also covered with a longer and thicker hair, for the more certainly holding the prey, and are terminated by black claws, and they are much smaller and more capable of motion every way. The belly is either white, or of a pale yellow, and is marked with a transverse black streak: this is surrounded with several other small spots of the same colour, and is cloathed with a very fine and short down. The whole body beside is covered with longer hairs, and is of a whitish or brownish colour. The apex of the head, the shield of the breast, and the ends of the forceps, are as hard as a crab's claws, but the rest of the body is covered with a tender and supple skin. The eyes are very large, and of a fine shining black; they are continually in motion, and when seen in the night or in a dusky place, they shine like the eyes of a cat. In the place where the mouth is placed in other animals, there arises in this a black hard forceps; the upper part of this instrument is covered with a yellow hairyness, and it is terminated by extremely fine and sharp claws, which the creature can open or close up at pleasure. While the arms hold the prey in a proper position, these sharp points make wounds in the body, and the other parts of the forceps squeeze the body till all its juices are pressed out, and the creature feeds on them. The mouth is placed much below these, and stands exactly in the proper place to receive the juices expressed by this operation. The *tarantula* sleeps in his cave the whole winter, and a great part of the autumn and spring; and if during this time he is ploughed up, as is often the case, or is any other way taken out of his hole, he is found quite torpid and numbed, and is unable to do any mischief by biting.

The hole or mouth of a tarantulous cave always gives some idea of the size of the creature within: he makes it small if he enters while young; and as he grows larger he eats away more and more of the earth to widen it still more, so that the diameter of it is usually about equal to the diameter of the body. The size of a chesnut is about the standard of a full grown *tarantula*; but there are some old ones found much larger and more hairy. The female is known from the male by having longer legs and a larger belly. They copulate in June and July, and at that season the females are often met with in the fields carrying the males upon their back In August and September they lay their eggs, which remain the whole winter; and in the summer after are hatched. Pliny tells a story of the young ones always eating up their mother for the first food, which is countenanced by the relation of the peasants in those parts, who say that they all swarm about her and suck her juices from many places at once, till they leave her lifeless carcass on the field, and then go each their several way in search of other food. The bite of the *tarantula*, as it is called, is not properly a bite, but a wound inflicted in a very peculiar manner. The creature pierces the skin with its forceps, and at that instant injects from its mouth a poison into the wound. The time in which their wounds are fatal, is that of their copulation; at this time they are in their utmost vigour and power of hurting. People of fashion are rarely hurt by them, but principally the poor labourers, who sleep half naked in the field, and the women who travel the country with naked feet, gathering medicinal herbs.

Authors are divided about the nature of the poison of the *tarantula*. Cardan says it is a cold one, and Scaliger says it is a hot one; but be this as it will, its effect is very sudden: it is no sooner received into the flesh but the veins take it up and carry it to the heart, where it becomes diffused thro' the whole mass of blood, and gives an immediate trembling of the limbs, and a difficulty of breathing. The next part it seizes is the brain, where it produces different effects in different subjects; and according to their state of health, and the condition of their juices, brings on various species of phrensies.

The

The patient sees a thousand phantoms, sometimes all jovial and merry ones, and sometimes imaginary scenes of blood and cruelty. Some are fond of seeing little streams of water trickling down into a bason; others are never easy unless they have green leaves before them: this indeed is almost an universal symptom. Some are delighted with various colours, and some are fond of violent motion, such as dancing, leaping, and the like; and some are in love with slow and graceful movements, as walking majestically, bowing, and dancing slow dances. Some are military mad, and call out for the noise of drums and trumpets, and the clashing of swords; but all of them, as well the brisk and noisy as the lethargic and dull, are pleased with music.

They will get up and dance to any instrument; and the moment it ceases playing they will fall down to the ground as if apoplectic, and not stir again till the music is renewed. Many people have laughed at the whole history of the bite of the *tarantula*, from this one accident of its poison being cured by music; but all who have been upon the spot attest it; and there seems no reason to call in question the various authorities on which we have it related. *Valett.* de Phalang. Apulo.

Phalangium *decticum*, in natural history, a name given by all the old Greek writers to a poisonous kind of field spider, the same with the *solipuga* of the Latins, or *solifuga*, as some write it. It is a small insect that buries itself in the sand, and if it bites a man does very great mischief; the part swelling, and the person becoming sick as if bitten by a viper: some say the bite is actually mortal; but this seems to be going too far. Solinus tells us that this creature is peculiar to Sardinia, but we find Pliny mentioning it in Ethiopia; and Lucan tells us that it was one of the poisonous reptiles that were in his time the pest of Africa.

Phalangium, *spiderwort*, in botany, the name of a genus of plants, the characters of which are these: The flower is liliaceous, and consists of four petals; from the center of which there arises a pistil, which finally becomes a roundish fruit divided into three cells, and filled with angular seeds; to this it is to be added that the root is fibrous.

The species of *phalangium*, enumerated by Mr. Tournefort, are these: 1. The large flowered not branched *phalangium*. 2. The small flowered not branched *phalangium*. 3. The branched *phalangium* with small flowers. 4. The iris-leaved alpine marsh *phalangium*. 5. The iris-leaved English marsh *phalangium*. 6. The least iris-leaved Scotish marsh *phalangium*. *Tourn.* Inst. p. 368.

PHALANGOSIS, in surgery, the name of a tumor and relaxation of the eye-lids, which is often so great as to deform the eye, and very much impede vision. Sometimes the relaxed eye-lid subsides or sinks down, occasioned either by a palsy of the muscles which sustain and elevate the eye-lid, or else from a relaxation of the cutis above, from various causes. Sometimes also an œdematous or aqueous tumor is formed on the eye-lids, so as almost entirely to exclude vision; but this last case should be well distinguished from the other, and may be remedied without much difficulty, by the use of internal and topical medicines; such as purges and diuretics given inwardly, and a compress dipped in warm spirit of wine and lime water.

But in the paralitic or relaxed case, the use of cordial and nervous medicines must be proposed internally, and outward ly balsam of Peru and hungary water are to be employed. If all these fail, the remaining method is to extirpate a sufficient quantity of the relaxed cutis; and then, after healing up the wound, the remainder will be sufficiently shortened. *Heister's* Surgery, p. 367.

PHALANX (*Cycl.*) — Phalanx, in natural history, a term used by Dr. Woodward, and some other writers of fossils, to express an arrangement of the columns of that sort of fossile coralloide body found frequently in Wales, and called *lithostrotion*.

In the great variety of specimens which are found of this, some have the whole *phalanx* of columns cracked through, and others only a few of the external ones; but these cracks never remain empty, but are found filled up with a white spar, as the smaller cracks of stone usually are. This is not wonderful, as there is much spar in the composition of this fossil; and it is easily washed out of the general mass to fill up these cracks, and is then always found pure, and therefore of its natural colour white.

The *lithostrotion* or general congeries of these phalanges of columns, is commonly found immersed in a grey stone, and found on the tops of the rocky cliffs about Millford in Wales. It is usually erect, tho' somewhat inclining in some specimens, but never lies horizontal. It seems to have been all white at first, but to have been since gradually tinctured with the matter of the stone in which it lies. The single columns which form each *phalanx*, are usually round or cylindric, tho' sometimes flatted and bent; some of them are also naturally of an angular figure; these, however, are not regular in the number of their angles, some consisting of three sides, some of five, and some of seven; some are hexangular also, but these are scarce. They are from five or six to sixteen inches in length; and the largest are near half an inch over, the least about a quarter of an inch; the greater number are very equal to one another in size; but the sides of the columns being unequal, the same column measures of a different thickness when measured different ways: the phalanges or congeries of these are sometimes of a foot or more in diameter.

The columns are often burst, as if they had been affected by external injuries; and it is evident, that they were not formed before several other of the extraneous fossils; for there are found sometimes shells of sea-fishes and entrochi immersed and bedded in the bodies of the columns. It appears plainly from hence, that when these bodies were washed out of the sea, and tossed about in the waters which then covered the tops of these cliffs, which cannot reasonably be supposed to have been any other than those of the universal deluge; this elegant fossil, together with the stony bed in which it is contained, were so soft that these other bodies found entrance into their very substance, and they were formed, as it were, upon them. This fossil takes an elegant polish, and makes in that state a very beautiful appearance, being of the hardness of the common white marble, and carrying the elegant structure visible in the smallest lineaments. *Woodward's* Coll. of Foss. p. 11.

PHALARIS, in the Linnæan system of botany, the name of a peculiar kind of grass called *phalaroides* by Scheuhzer and others; and with this author making a distinct genus of plants, the characters of which are: That the cup is a glume, containing only one flower; this glume is large, bivalve, obtuse, and compressed, each of the valves being of a boat-like shape, flatted, obtuse above, with strait edges meeting one another in parallel lines. The flower is also bivalve, and is smaller than the cup; the exterior valve of it being oblong, pointed, and folded, the interior much smaller. The stamina are three capillary filaments, shorter than the cup; the antheræ are oblong; the germen of the pistil is roundish; the styli are two in number, and are capillary ones; the stigmata are hairy; the flower serves for a close covering to the seed, not at all gaping from it; the seed is single, smooth, and roundish, but pointed at both ends. *Linnæi* Gen. Plant. p. 14.

PHALENÆ, in natural history, the name by which authors distinguish those butterflies which fly by night, and which the French thence call *papilions nocturnes*, and we vulgarly *moths*.

All the creatures of this class are quiet by day, remaining fixed to the stalks or leaves of plants, except only some of the males, which are now and then found fluttering about in the woods in search of the females; but as soon as night approaches they all fly about. This disposition is very remarkably implanted in their nature; for when kept shut up in boxes they always remain quiet without changing place all day, but as soon as the sun is about setting, they always begin to flutter about and fly as much as their prison will permit them. The species of these are more numerous even than those of the day butterflies. The day kinds all have trunks fitted for the sucking the juices of flowers for their nourishment, but many of the *phalenæ* wholly want them: these, however, have always the beards which serve to defend the trunk from injuries in the day-flies, and sometimes in the place of the trunk within these, there is found a small white protuberance or two. It is certain, therefore, that many of the *phalenæ* have no organs of eating, nor take in any food during their whole lives in that winged state. *Reaumur's* Hist. of Inf. Vol. i. P. 1. p. 363.

The grand distinction of the *phalenæ* is into those which have trunks, and those which have not; or at least which have not any sensible to the eye of a common observer; according to these, and to other essential distinctions, these, in the manner of the *papilios* or day-flies, are arranged into seven classes. See Papilio.

Class 1. This contains the *phalenæ* which have prismatic antennæ, or such as are of an equal thickness in almost all their length, and have their anterior part rounded, but their hinder part formed of two planes meeting in an angle; so that a transverse section of one of these antennæ represents a curvilinear triangle. All the *phalenæ* of this class have trunks, and the greater part of them have their wings so disposed, that they form a flat surface when the creature is at rest, and leave the upper part of the body naked; and this usually terminates in a point. The inferior wings are small in comparison of the superior, and their inferior edge is shorter, and usually very much so, than the superior; and the end of this reaches to the end of the body, or beyond that, whereas the other usually leaves two or three rings of it uncovered.

Those moths which have large and heavy bodies, and have short under-wings, and narrow, tho' long upper ones, always make a great noise in flying, and cannot support themselves in the air without agitating their wings very swiftly. This is also the case with some of the day-butterflies.

Many of the very large and beautiful *phalenæ* are of this first class, particularly that which is produced of the beautiful spurge caterpillar.

Class 2. This comprehends the *phalenæ* which have conic horns or antennæ, which regularly decrease in diameter from their

their origin to their extremity, and terminate in a very fine point. These *phalenæ* also have trunks, as well as those of the former class; and their antennæ are usually very slender.

Class 3. This comprehends the *phalenæ* which have antennæ of the same form with those of the former class, but have no trunk.

Class 4. This comprehends the *phalenæ* which have bearded antennæ and a trunk.

Class 5. This comprehends those which have bearded antennæ and have no trunk.

There are several genera of each of these classes, distinguished by the particular structure of their antennæ, tho' of the general form described in the character of the class. Those which are composed of several vertebræ joined end to end, which make the length, have great differences in the size and proportion of these joints, and some of them are hairy, others smooth. These, however, tho' very certain and unerring distinctions, are not to be perceived without the assistance of the microscope; whereas the same animals offer us much more plain and obvious distinctions, and those equally certain, in the different manners in which they fly, and carry their wings when at rest. The butterflies have different manners of carrying their wings, but these are but few in comparison of the moths; so that if the classes in these last were to be established according to this character, they would be greatly too numerous; tho' this gives very happy subdistinctions of the peculiar genera of each class, of which we shall give some instances hereafter, in regard to this class.

Class 6. This comprehends a very peculiar sort of *phalenæ*, the females of which have no sensible wings. Several of those caterpillars which have long parcels of hairs at their heads resembling horns, give *phalenæ*, the females of which have no wings; and the creeping ones, with ten legs, also give some. *Reaumur's* Hist. Inf. V. 1. P. 1. p. 408.

Class 7. This comprehends a set of *phalenæ* which are much more distinctly charactered by nature than any of the former: they have wings shaped like those of birds, and composed of true and proper feathers. All the *phalenæ* of this class are small, but their singular structure makes them worthy a peculiar attention.

It is scarce possible to determine exactly, whether they belong to the *phalenæ* or butterfly class most properly: they have the conic antennæ, which character a former class of the *phalenæ*; but they are often found flying about in the day time, in the manner of the day-flies: their changes also are made in the same manner with those of the day-flies; so that upon the whole, it is, perhaps, most proper to account them a peculiar class of the *papilio*, considered as a general term, but without regard to the first distinction of day and night kinds, or of moths and butterflies.

There are three genera of this class, each of which carries its distinctions from the others very obvious and distinct, so as not to be in any danger of being mistaken.

Those of the first genus are all of a remarkable whiteness; they always stand upon all their six legs, and the two hinder ones are much longer than the others. This creature never carries its wings lying on its body, as the generality of *papilios* do; but they are placed in a direction perpendicular to the length of its body, or nearly so. When it is at rest, the wings are closed somewhat in the manner of those of birds; yet in this state we may see that they are made of feathers, which, when we view them with the microscope, appear to be so many segments into which the wings are divided; the upper being divided into two, and the lower into three, each of which is edged on both sides with real feathers. Mr. Hook has figured this creature in his micrographia, and has given but two divisions to the under wing; but that was probably an oversight, the middle one being easily overlooked. When this little creature flies, it separates the segments of its wings farther off, and expands its feathers so, that they perfectly resemble those of a bird; and the two wings are in this state so placed together as to resemble only one. As beautiful, however, as these wings are to look at, they are but of very little use to the creature in flying. It is not known to fly at all by night, and in the day it takes only very small and short flights.

The creature given by Reaumur as an instance of the second genus of this class, is of a fine bright brown colour, as are all of the genus. When this creature is in a state of rest, its wings are not seen to be feathery, nor even to be wings at all; but are so folded up, as to resemble arms stretched out at length: and the creature in this posture looks like the miniature figure of a man upon a cross, the two wings of each side being folded into a sort of cord, and turning hooked at the ends. The inferior wings are composed each of three plumes, and are lodged in a furrow made by the upper ones, which are convex externally, and concave within, and are divided only about a sixth part of their length, but their segments are well feathered at the edges for half their length.

This species also differs from the former, in that it stands only on its four anterior legs, the two hinder ones being usually extended along the sides, and forming a sort of tail after they have crossed one another behind.

The creatures of the third genus of this class are small, and are frequently seen on the glass of our windows; and their wings are the most truly plumose of those of any species. They are of a brown colour, with somewhat of a gilded look when closely viewed, and have a few black spots in different parts. They carry their wings flat, or horizontally, when at rest; and these appear like the wings of the common butterfly, but when nearly examined, they are found to be composed of real feathers; and their seeming continuity is only owing to the close arrangement of these feathers. This is a very tender creature, and easily crushed to pieces; but when caught carefully, and examined by the glass, each upper wing is found to be composed of eight feathers, and each under one, of four; and the quill part of the pedicle of these feathers, is in all the wings separate to the very point at the top, which is very different from the others, where the wing is only divided a little way into segments; and the upper and under wing of each side are so nicely fitted together when the creature flies, that they only resemble one very large wing. Yet even these feathered wings, when viewed by powerful microscopes, are found not to be truly feathered; but what we term plumes are in reality only a nice arrangement of scales, like those of other butterflies upon the deep segments of the wing. This species has conic antennæ and a trunk. Its origin is unknown, but it seems to be produced of some of the teniæ which live in our houses, since it is always found within doors, never in the fields; and is seen in the month of March, which is earlier than the field butterflies are seen: they are also found in August, September, and October, and sometimes later than that month. *Reaumur's* Hist. Inf. V. 1. P. 1. p. 419.

Mr. Reaumur has given an example of the manner of distinguishing the subordinate genera of the other classes, in those of the second, fifth, &c. before mentioned. In this he has regard to the position and direction of the wings, which is sufficiently certain and determinate, and is the most obvious of all characters; according to this he has established the following genera of this extensive class:

Genus 1. The *phalenæ* of this genus carry their wings parallel, and in an horizontal direction; but they cross one another, one of the upper wings lying in great part over the other. Sometimes it is the right that crosses over the left, and sometimes the left that crosses over that; but however this be, the under wings always lie folded underneath them. Many of the caterpillars which feed on our garden herbs, afford *phalenæ* of this genus, of which there are several of the second class.

Genus 2. This comprehends those *phalenæ* whose wings lie parallel, as in the former genus: they also cover in the same manner the under wing, but these never cross one another. Of this genus there are several subdivisions.

Genus 3. This comprehends those *phalenæ*, the upper wings of which have their interior edges applied one against the other: and tho' they are in general held parallel to the horizon, yet that part of them which covers the body has not the same parallelism with the rest; but are bent round about the body, and so moulded, as it were, upon it, that they shew the shape of that part of it which they cover. We have an instance of this genus in that *phalena* which is produced of the caterpillar which feeds upon the young and green seeds of the nettle. Its wings are variegated with white, and with a deep brownish black, in an elegant manner.

Genus 4. This genus comprehends those *phalenæ* which carry their upper wings in an horizontal direction, but which, instead of crossing, or even touching one another, are so wide asunder, that they do not cover any part of the body, but leave both that and the under wings naked. This genus comprehends a great number of species, which are distinguished according to the different distances to which they expand the wings in sitting; some having them little less so at rest than when flying.

Genus 5. This comprehends those which have the interior edges of the upper wings joined one to the other, and raised above the surface of the body, so that they form a sort of canopy over the creature. In this case, the under wings are always necessarily hid. We have an instance of this genus in the second class, one of the *phalenæ* of that being a very beautiful one, variegated with red and black, always carrying its wings in this manner very remarkably.

Genus 6. This comprehends a set of *phalenæ* which somewhat resemble the former in the placing of their wings, insomuch, that they meet at the interior edges, and form a canopy over the body; but as this is strait and angular in the former genus, it is rounded or arched in this: the inner part of each outer wing being bent, as it were, into the shape of the body. We have a very frequent instance of this genus in one of the *phalenæ* of the third class, which has conic antennæ and no trunk: the caterpillar of this species feeds on the rotten trunks of trees.

Genus 7. This comprehends a great number of *phalenæ*, the greater part of which are very small in size, and carry their wings almost horizontally, forming a very depressed canopy over their bodies. These are remarkably thick about the shoulders, or origin of the wings, and are known by many by the name of the *large-shoulder'd*. When these are in a state of rest, their largest diameter is either at the origin or at the middle of the breast, at or near the insertion of the wings.

We have many *phalenæ* of this kind produced from thofe caterpillars which artfully roll up the leaves of trees, particularly one bred from a fmooth caterpillar of this kind, with fixteen legs.

Genus 8. This comprehends thofe *phalenæ*, the wings of which are laid clofe down upon the body, fo as to be moulded on it, and take its exact fhape: thefe cover the body exactly as the wings of birds do theirs. There are numbers of fmall moths of this fpecies, which are produced of thofe kinds of caterpillars which live all their time in fociety in one common web; of thefe there are many fpecies.

Genus 9. This comprehends a fet of *phalenæ* fmaller than the former, which carry their wings in the fame manner, clofely folded upon their bodies; but differing in this, that they are extended to a confiderable length, and towards their extremity rife up above the level of the body, and form a fort of tail like that of a cock. The *phalenæ* of this genus are diftinguifhed by fome under the name of *cock-tailed*; and tho' they are fmall, yet they are very numerous, and of very great variety; and when examined with the microfcope, appear of a beauty equalling almoft any kind. Their wings thus viewed are frequently found variegated with gold and filver in appearance, the yellow and white fpots frequent in them having a brightnefs which a painter could give us no idea of, but by ufing thofe metals. The moths of the teniæ of feveral fpecies are of this kind: their antennæ are ufually of the conic kind, and as flender as hairs; and it is difficult to fay whether they have any trunk, it being, if they have any, of a very minute kind.

Genus 10. This comprehends a fet of *phalenæ* whofe upper wings are very remarkably folded over the body, one of them furrounding it in a manner, and the other turning itfelf fpirally round that; fo that a very great part of one of the upper wings is always covered by the other. *Reaumur*'s Hift. Inf. V. 1. P. 1. p. 394, 396.

PHALERA, the name of a bandage for the nofe, defcribed by Galen in his treatife on bandages.

PHALERÆ, among the antients, horfe-trappings. See the article TRAPPINGS.

PHALLUS *marinus*, a name given by fome authors to a fpecies of *canalis* or *tubulus marinus*, found about Amboina, and called by the French writers *priape* and *arrofoir*. It is an oblong fhell, with a large head, which is pierced full of holes; fo that it at once refembles the *glans penis*, and the nofe of a watering-pot ufed by gardeners.

PHARI, among the antients, a kind of candleftick. See the article BRANCH.

PHARICUM, the name of a famous poifon among the antients: it was faid to be compofed of many ingredients, but we know nothing of it at this time.

PHARMACI, φαρμακοι, among the Greeks, an appellation ufed for two perfons who were employed in the luftration or purification of cities. *Pott.* T. 1. p. 400.

Thefe were two men, according to fome; but others fuppofe them to have been a man and woman, to reprefent the male and female fex, for each of which they offered a facrifice. It was ufual for the man to carry about his neck figs, called ισχαδες, of a blackifh colour; and the woman fuch as were white. *Pott.* Archæol. Græc. T. 1. p. 400, feq. See the article LUSTRATION, *Cycl.*

PHARMACIA, φαρμακεια, in antiquity, denotes the art of effecting ftrange and wonderful things, by means of medicated and inchanted compofitions of herbs, minerals, *&c.* Thefe things themfelves were called *pharmaca*, fome of which being taken inwardly, were faid to caufe blindnefs, madnefs, love, *&c.* Such were the medicaments by which Circe transformed Ulyffes's foldiers; others infected by touch, fuch was the garment Medea fent to Creufa; others fpread their venom afar off, and operated upon perfons at a great diftance.

There were alfo *pharmaca foteria*, φαρμακα σωτηρια, which were amulets againft the former; fuch was the herb moly, which preferved Ulyffes from Circe's inchantments; the laurel, the fallow-tree, the rhamnus, or Chrift-thorn, flea-bane, the jafperftone, and many others mentioned by Albertus Magnus, and Orpheus, in his book de lapillis. *Pott.* Archæol. Græc. l. 2. c. 18. T. 1 p. 353. See AMULET.

PHARMACITIS *terra*, in the materia medica, a name which fome authors have given to the common *ampelites* or cannelcoal. See AMPELITES.

PHARMACOCHEMIA, a term ufed to exprefs that part of the chemical art which treats of the preparation of medicines.

It is thus called by way of diftinction from that chemiftry which is wholly employed about the tranfmutation of metals by means of the philofopher's ftone; this being called *fpagirico-chemia*.

PHARMACY *(Cycl.)*—Moft of the natural bodies being fome way or other employed as fubjects of *pharmacy*, the materia medica is extremely large, and its operations various. Its materials in the earlieft ages, indeed, were very few, and the ways of managing them very fimple: fubjects afterwards multiplied, operations increafed, and at prefent we feem abundantly ftocked with both fimple and compound medicines.

Difeafes muft have been very early, if the firft inhabitants of the earth experienced the fame changes of feafons, breathed the fame kind of air, and ufed a like kind of diet and regimen of life with ourfelves: but foon after the difeafe afflicts, the patient feeks a remedy; and this appears to have been the foundation of *pharmacy* in different parts of the world.

Experiments being thus multiplied, and the preparations of fimples better made, *pharmacy* became at length an art. Hippocrates, however, when he came to compile a kind of fyftem of phyfic from the obfervations of antiquity, defcribed but few, and thofe generally fimple. *Shaw*'s Lectures, p. 193. Succeeding phyficians then enlarged the materia medica; Galen confiderably fwelled the catalogue, and the Arabians much more; and when learning began to revive in Europe, the materia medica was again enlarged, and great changes wrought upon it by chemiftry.

The art of *pharmacy* muft be confidered under the management of phyficians, apothecaries, trading chemifts, and druggifts. To the phyfician it belongs to direct the medicines, and to give the rules of extracting and managing the fimples. To the apothecary belongs the reduction of the materia medica into certain forms of medicines, according to the direction of the phyfician. And the defign of trading chemifts and druggifts, is to furnifh medicinal matters to the apothecary, who cannot always detect an artificial counterfeit, or a dexterous fophiftication; and perhaps many remedies, well defigned by the phyfician, have failed or had mifchievous effects on this account. *Shaw*'s Lectures, p. 195.

PHARMUTHI, in the Ægyptian chronology, one of the months of their year, which anfwered to the month of April among the Romans *Hoffm.* Lex. univ. in voc.

PHARYNGÆUM *fal*, a name given by authors to an artificial falt, of ufe in the quinfey, and cafes of the like kind, when the *pharynx*, or fauces are incommoded by a difcharge of ferous or other humours.

It is prepared of cream of tartar and nitre, each an ounce, with half an ounce of burnt alum; all thefe are to be diffolved in vinegar, and coagulated according to art. This falt mixed with honey, and diffolved in plantain water, makes an excellent gargle.

PHASEOLUS, *kidney-bean*, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the papilionaceous kind, and its piftil, which arifes from the cup, finally becomes a long pod, containing feveral kidney-fhaped, or elfe oval feeds. To this it is to be added, that the leaves always ftand three upon a ftalk, and the whole trace and habit of the plant is peculiar, and diftinguifhes it from the other papilionaceous flowered genera.

The fpecies of *phafeolus*, enumerated by Mr. Tournefort, are thefe: 1. The common garden *phafeolus*. 2. The common *phafeolus*, with black fruit. 3. The common *phafeolus*, with yellow fruit. 4. The common *phafeolus*, with red fruit. 5. The common *phafeolus*, with livid fruit. 6. The common *phafeolus*, with pale coloured fruit. 7. The common *phafeolus*, with violet coloured fruit. 8. The common *phafeolus*, with fruit variegated with black and red. 9. The common *phafeolus*, with white fruit, variegated with black lines and fpots. 10. The common *phafeolus*, with purple fruit, variegated with circles of white. 11. The leffer garden *phafeolus*. 12. The leffer *phafeolus*, with pods bending upwards, and with white fruit. 13. The black-fruited leffer *phafeolus*, with pods bending upwards. 14. The white-fruited leffer *phafeolus*, with pods bending upwards, and with black or purple circles variegating the fruit 15. The large *phafeolus*, with broad white fruit, ftriated with numerous black veins 16 The large *phafeolus*, with broad, compreffed, perfectly white fruit. 17. The large *phafeolus*, with large flat white ftriated fruit. 18. The large *phafeolus*, with fmall fnow-white tumid fruit. 19. The *phafeolus*, with greenifh black fruit, refembling thofe of the anagyris. 20. The *phafeolus* with red fruit, refembling that of the anagyris. 21. The fmall *phafeolus*, with white fruit, marked with a black fpot. 22. The narrow-leaved exotic *phafeolus*. 23. The narrow-leaved exotic *phafeolus*, with variegated black and white fruit. 24. The fmall-leaved foreign *phafeolus*, with white, and fometimes with variegated fruit. 25. The foreign *phafeolus*, with the pod and the fruit both black. 26. The foreign *phafeolus*, with variegated fruit. 27. The foreign *phafeolus*, with reddifh fruit, variegated with black lines. 28. The foreign *phafeolus*, with white fruit, of the fhape of a pigeon's egg, and marked with a fingle black fpot. 29. The foreign *phafeolus*, with black fruit, variegated with a white fpot. 30. The Æthiopian *phafeolus*, with black pods, ridged with rough veins, and with a black fhining feed. 31. The Æthiopian *phafeolus*, with yellow leaves and a black feed. 32. The Æthiopian *phafeolus*, with deep red pods and black feeds. 33. The black-fruited Ægyptian *phafeolus*. 34. The red-fruited Ægyptian *phafeolus*. 35. The American *phafeolus*, or lablab, with rofe-coloured fruit. 36. The Indian *phafeolus*, with cochleated flowers. 37. The fcarlet-flowered *phafeolus*. 38. The fmalleft flowered *phafeolus*, with a green fruit of an oval fhape. 39. The garden *phafeolus*, with white fmall oval feeds. 40. The American *phafeolus*, which propagates itfelf by its tendrils. 41. The African *phafeolus*, with fmall white fruit. 42. The fmalleft *phafeolus*, with very long pods. 43. The Brafilian *phafeolus*, with a black fruit, of the fize of a pea. 44. The fmall perennial African *phafeolus*, with bright

bright red flowers. 45. The American *phaseolus*, with a sinuated and spear-pointed leaf. 46. The knotty-rooted American *phaseolus*, with purple flowers, and very narrow pods. 47. The knotty-rooted American *phaseolus*, with yellow flowers and knotty pods. 48. The hairy *phaseolus* of America, with knotted pods. 49. The largest American *phaseolus*, with a great pod, and a hard scarlet fruit. 50. The large American *phaseolus*, with a great flower and with slender crooked pods. 51. The hairy American *phaseolus*, with jointed pods. 52. The American *phaseolus*, with a tuberous esculent root, and with hairy, and, as it were, jointed pods. 53. The American *phaseolus*, with a cochleated flower, and falcated pods. 54. The American sea *phaseolus*, with a hard fruit and variegated seed. 55. The American *phaseolus*, with small pods and variegated seeds. 56. The American *phaseolus*, with a pyramidal spike of flowers, and red seeds, marked with a black spot. 57. The American *phaseolus*, with a remarkable large vexillum to the flower, and with strait cylindric-shaped pods. 58. The round-leaved sea *phaseolus*, with a purple flower, a short-crested pod, and brown striated seeds. And, 59. The pernicious wood *phaseolus* of America, with open pale purple flowers, and slender black pods, and small spotted seeds. *Tourn.* Inst. p. 412. seq.

There are at present three sorts of *kidney-beans* propagated for the table in England. These are, 1. The common white or Dutch *kidney-bean*. 2. The smaller *kidney-bean*, commonly called the Battersea *kidney-bean*. And, 3. The upright sort, called the tree *kidney-bean*.

The first sort was sometime ago greatly propagated in England, and is still in Holland: it grows very tall, and requires long stakes and poles to climb on, and its beans are considerably broad; this makes them less saleable in the markets, people supposing them to be old because they are broad; and they are hence grown into disuse, tho' a much more valuable kind for eating than any other.

The second, sort or Battersea bean, is what is more universally cultivated; it never grows very tall nor rambles far, and the air can easily pass between the rows, because of its moderate growth; and this makes it bear plentifully and ripen well for the table. It is the best-tasted bean, except the last.

The third, or tree *kidney-beans*, is also a plentiful bearer, and never rambles, but grows up in form of a shrub; but its beans are broader than the Battersea kind, and are not so well-tasted.

They are all propagated from seeds which are to be put into the ground in the latter end of March or beginning of April for an early crop, but these should have a warm situation and a dry soil; they must also be planted in a dry season. The manner of planting them is, to draw lines with a bough over the bed, at two foot and a half distance, into which the seeds are to be dropped at about two inches asunder, and the earth is to be drawn over them with the head of a rake, to cover them about an inch deep. In a week after sowing, the plants will appear, and the earth should be drawn up about their stalks as they rise up; for a few days after this they will require no farther care, except to be kept clear from weeds, and when the beans appear, to have them gathered twice a week; for if the beans are suffered to hang on too long, they not only become of no value, but they weaken the plant.

The first crop of *kidney-beans* will continue a month in good order; and to supply the table afterwards, there should be fresh sowings in March, April, May, and June, the last of which will continue till the frosts come to destroy them. Some raise their early crops on hot-beds; and this is to be done exactly in the same manner as the raising the early cucumbers. *Miller's* Gard.Dict. See the article CUCUMBER.

PHASSACHATES, in the natural history of the antients, the name of a species of *agate*, which, in its different appearances, they sometimes called also *leucachates* and *perileucos*.

The same *agate*, from the various proportion or manner of admixture of its particles in different specimens, often makes a very different figure; but no species is so liable to remarkable diversities of this kind as this. It is but of a small variety of colours, yet is often very beautiful; its ground or basis is always a pale bluish grey, approaching to what we call a lead colour, or dove colour. Sometimes it is equally and evenly of this colour, thro' the whole mass, but often also it is variegated within with veins of a deep black and of a pure and clear white: these sometimes approach the surface of the stone, but more usually they are only near the center; and they are almost always disposed in concentrical, but irregular circles, round one, two, or more points. The pieces of this stone, cut where there are many of these veins, much resemble parts of onyxes.

It is found in the East Indies, and in Bohemia, and some other parts of Europe. When the whole matter of the veins and basis of this stone are all blended together into one equal mass, as is frequently the case both with this and many other of the naturally veined stones, the whole becomes of a deeper greyish blue, or a dove colour, and is then the *phassachates*; when the veins are kept distinct and clear, it is the *leucachates* and *perileucos*, agreeing with all the descriptions of the antients. *Hill's* Hist. of Foss. p. 480.

PHAUSINGES, a name given by the antients to red circles on the legs, occasioned by fire: it is by some also extended to several other spots and blemishes on the skin.

PHEANTIDES, in natural history, a name given by some to the stone called *encymonites*; it was of the nature of our sparry incrustations on the roofs of subterraneous caverns. It was supposed to have great virtues in promoting delivery, and was given to women when they fell in labour.

PHEASANT, in ornithology, a bird so nearly allied to our common poultry, that it would naturally appear a very easy thing to breed them up from young; but the proper food of them is not sufficiently enquired into. Tho' they eat corn when full grown and in health, yet they have recourse in their young state, and when sick, to another sort of food, preying on several insects, and that in a very voracious manner.

The young *pheasants* and partridges prey upon ants; and they will never succeed with us if they have not a proper quantity of ants to have recourse to, as soon as they leave their roost in a morning. When musty corn, or want of due care in cleaning their houses has made them sick, a repast of ants will often recover them. When that fails, they may be offered millepides or ear-wigs, or both together, which will always do much better than either singly. To this medicine must be added a proper care that their common food of corn be very sweet, their habitation kept nicely clean, and their water shifted twice a-day. They must not be let out of the house in a morning till the dew is off the ground; and after sun-set they must be immediately taken in again: in the heat of the day they must be allowed to bask in the sun in a dry sandy place. With these regulations the birds of this kind will succeed much better than they usually do. The *pheasant* is a bird of a sullen disposition, and when the coupling time is over, there are seldom found more than one in a place. Phil. Trans. N° 23.

The way of taking *pheasants* is, first to be acquainted with their haunts and breeding places; which are usually young, thick, and well-grown coppices, free from the disturbances of cattle, and having no path-way thro' them, for the *pheasant* is an extremely timorous bird. When the haunts are discovered, the next thing to be attempted is, to find where the eye or brood is. In order to this, it is to be considered, that the *pheasant* comes out of the wood three times a-day to feed in green corn, fresh pastures, or the like places The times of coming out are in the morning soon after sun-rise, at noon, and at sun-set. The sides of the wood where they are supposed to come out, are to be carefully watched on this occasion, and the young ones will be seen following the female just as a flock of chickens follow the hen. The wood may be also well watched in the evenings, and the noise of the cock and hen calling the young ones together will soon be heard; and the sportsman is on this occasion to get as near as he can to the place, and being very still and silent he may observe their numbers and disposition, and learn how to spread his nets so as to take the whole brood with great ease; but if his least motion when near them discover him, they will all take to their legs and run to a great distance; they seldom rise on the wing, except very close frighted indeed. Practice will make some people so expert at the imitating the voice of the old *pheasant*, that he will be able to call the young ones together to any place that he pleases, when the haunts are once found out, and by this means they are easily led into the nets.

The best time for using the call is, in the morning or evening; and the note imitated should be that by which the old ones call them out to feed; but by learning to imitate the other notes they will be brought together at any time of the day. The sportsman who can make this call, must shelter himself in some close place, and begin by very softly making the note; then if none are near enough to be within hearing, he is to raise it to more and more loudness, and at length he will be answered as loud, if any are within hearing, tho' at a considerable distance; whereas if he should set up the call too loud at first, and any of the birds should happen to be very near, they would be frighted away.

As soon as a *pheasant* answers, the sportsman is to creep nearer and nearer, still calling, tho' not so loud; he will still be answered, till at length he will be led by the bird's voice within sight of her. As soon as this is the case, he is to spread his net, and then begin to call again, keeping in some close and well-sheltered place behind the net: in this place he is to call till the bird approaches; and when he has drawn her under the net, he is to appear suddenly, and the bird rising up will be caught in the net.

Another method of taking *pheasants* much quicker than by this means is, the having a live cock *pheasant* to use as a stale: this bird is to be fixed under the net, and by his crowing he will soon entice others in. The sportsman must lie concealed, and as soon as another *pheasant* comes in, he is to draw the net over him. Many people have a method of taking *pheasants* in springes or horse-hair snares: the succeeding in this depends on the carefully searching out their haunts and the places by which they go out of the woods into the fields. When these are found, a peg is to be fixed in the ground at each, and at each peg two springes are to be laid open; the one to take in the legs, the other the head. As

soon as the springes are set, the sportsman is to go into the woods, and getting behind the birds, he is to fright them with some little noise, such as shall not be enough to raise them to the wing, but only to set them a running. They will naturally make their way out of the wood thro' their accustomed passes, and be then caught in the springes.

There is another method yet of taking these birds in the winter, provided that there is no snow. This is to be done with a net made like a casting net, but with the meshes much wider; they may be five inches wide. Some peas or wheat are to be taken out, and the path of the *pheasants* being discovered, which may easily be done by their dung, a pint or thereabout of corn is to be thrown down in the path in a place marked, so that the sportsman can come to it again. This is to be done for several days, till at length the *pheasants* are expecting it every day regularly; and all the birds of this kind that frequent the place, are brought together to feed there, and then the net is to be fixed over the place; its top being tied up to some bough of a tree, and its bottom fixed down all round, except in one place, where the walk of the *pheasants* lies. In this place it is to be raised in form of an arch, and the entrance is to be lined with several rods of hazel; the thick ends of which are to be tied to the net, and the thin ones let into the space covered by it; and thus the *pheasants* will easily get in by parting the small ends of the sticks, as fish into a wheel, but they will not easily get out again. The nets are to be dyed of a russet colour, by laying them in a tan-pit; and they must, when planted for this purpose, be covered with boughs, so that the birds do not discover them, and then they will easily run into them, and be all taken at once.

PHECOS, in botany, a name used by some authors for the *sagittari*, or *water-arrow-head*. *Ger.* Emac Ind. 2.

PHELLANDRIUM, *water-hemlock*, in botany, the name of a genus of plants, the characters of which are these: The flowers stand in umbells, and are of the rosaceous kind, each being composed of several heart-fashioned leaves, disposed in a circular form. The cup finally becomes a fruit composed of two small seeds, lightly striated and gibbose on one side, and flat and plain on the other.

The species of *phellandrium*, enumerated by Mr. Tournefort, are these: 1. The common *phellandrium*, or *water-hemlock*. 2. The alpine *phellandrium*, with purple umbells, called by some *meum alpinum* and *mutellina*. *Tourn.* Inst. p. 316.

PHELLOS, in botany, a name used by some authors for the cork-tree. *Ger.* Emac. Ind. 2.

PHELLOS, φελλος, in antiquity, a festival in honour of Bacchus, being a preparative to the Dionysia. See DIONYSIA, *Cycl. Potter*, T. 1. p. 436.

PHENGITES, in the natural history of the antients, the name of a very beautiful species of alabaster. It is a very rude and irregular mass, very shattery and friable, yet of a brightness superior to that of most of the other marbles, and excelling them all in transparence: it is in colour of an agreeable pale, yellowish, white, or honey colour; the yellowish is more intense in some places than in others, and sometimes makes an obscure resemblance of veins. It is very weak and brittle in the mass, and when reduced to small pieces, is easily crumbled between the fingers into loose, but considerably large angular pieces, some perfect, others complex, irregular, or mutilated, and all approaching to a flat shape.

The antients were very fond of this species in their public buildings; and the temple of fortune, built wholly of it, has long been famous. Its great beauty is its transparence; from which alone this temple was perfectly light when the doors were shut, tho' it was built without a window, and had no other light but what was transmitted thro' the stone its walls were built with. It was antiently found in Cappadocia, and is still plentiful there: we have it also in Germany and France, and in our own kingdom in Derbyshire, and some other counties. It takes an excellent polish, and is very fit for ornamental works where there is no great strength required. *Hill's* Hist. of Foss. p. 490.

PHEOS, in botany, a name given by Theophrastus, Dioscorides, and others, to a plant used by the fullers in dressing their cloths, and of which there were two kinds, a smaller, called simply *pheos*, and a larger called *hippopheos*.

The name of this plant is sometimes written *phleos*; and it is by that confounded with a kind of marsh cudweed, or *gnaphalium*, called also by that name; but it may be always found which of the two plants an author means, by observing the sense in which the word is used, and the use to which the plant was put. The *pheos*, properly so called, that is, the cudweed, was used to stuff beds and other such things, and to pack up with earthen vessels to prevent their breaking; but the *pheos*, improperly called *phleos*, only about cloths; this was, however, also called *stœbe* and *enaphon*.

Theophrastus describes the *pheos* and the *hippopheos*, and calls them the same plant, only differing in size and some other small particulars. And he says, in many places, that this plant was also called by many *stœbe*; he mentions them often together, and several times compares some one plant to them both; so that there seems to have been only the difference of size between them. Galen also, as well as this author, calls the *hippopheos stœbe*.

Dioscorides, however, has somewhat perplexed the matter, by describing the *pheos* and the *hippophes*, so he writes the *hippopheos*, in different places of his works, and not seeming to allow any similitude or alliance between them. The virtues he ascribes to them are also plainly different; he tells us, that the *stœbe* or *pheos* binds, is good in dysenteries; and, on the contrary, that the *hippopheos* is a purgative, and carries off the bile. The *stœbe* is numbered by him among the smooth plants, and the *hippopheos* among the prickly ones. Upon the whole, the names *stœbe* and *pheos* with this author, seem applied only to the plant properly called *phleos*, that is, *gnaphalium*; and he treats of this *stœbe* either as a thing universally known, or else as unknown even to himself; for he no where gives any description of it. *Theophrast.* l. 6. c. 5.

PHEREPHATTIA, Φερεφάττια, in antiquity, a festival at Cyzicum, wherein a black heifer was sacrificed to Pherephatta or Proserpine. *Potter*, Archæol. Græc. T. 1. p. 436.

PHILADELPHIA-*stones*, a name given by some authors to what are called by others *Christian's bones*, found in the walls of that city. It is a common error, that these walls are built of bones, and the tradition of the country is, that when the Turks took the place they fortified it for themselves, and built their walls of the bones of the Christians whom they killed there. Dr. Smyth in one of his epistles mentions this wall as an instance of the Turkish barbarity; but this is an idle opinion, what passes for bone being only a loose and porous stone of the sparry kind, found in an old aquæduct which is still in the wall. Sir Paul Rycaut brought home pieces of these stones, which he also supposed to have been bones, but on examination they proved to be no other than various bodies, chiefly vegetable, incrusted over and preserved in a spar of the nature of that which forms incrustations in Knaresborough spring, and other places with us. These bodies are often cemented together in great numbers by this matter, and their true shape lost in the congeries, till a diligent and judicious eye traces them regularly. *Woodw.* Catal. of Foss. V. 2. p. 14.

PHILANTHROPOS, in botany, a name used by some authors for the common *aparine*, *cleavers*, or *goose-grass*. *Ger.* Emac. Ind. 2.

PHILANDER, in zoology. See the article DIDELPHIS.

PHILETERIUM, in botany, a name used by some authors for the *behen album*, the common white flowered bladder campion, called *white ben*. *Ger.* Emac. Ind. 2.

PHILLEREA, a garden shrub, which, in the Linnæan system of botany, makes a genus, the characters of which are: That the cup of the flower is very small, indented into four seeming divisions, and does not fall off with the flower. The flower is composed of one petal, beginning with a very short tube, and dividing into four segments placed evenly, and each pointed; the stamina are short, two in number, and placed opposite one to the other; the antheræ single and erect; the pistil is composed of a roundish germen, a single style of the length of the stamina, and terminated by a somewhat larger stigma; the fruit is a single berry, containing one large orbicular seed. *Linnæi* Gen. Plant. p. 2.

PHILOMEDIUM, in botany, a name used by some authors for the *great celandine*. *Ger.* Emac. Ind. 2.

PHILONIUM (*Cycl.*)—PHILONIUM *Londinense*, the name by which the medicine commonly called *philonium romanum*, is called in the late London dispensatory. The composition is also much altered, as well as the name, and is now ordered to be made thus: Take white pepper, ginger, caraway-seeds, of each two ounces, opium six drams, syrop of diacodium boiled to the consistence of honey, three times the weight of all the rest. The opium is to be dissolved in a little wine, and then mixed with the syrup; after which the powders are to be stirred in, and the whole made into an electuary. *Pemberton's* Lond. Disp. p. 342.

PHILOSOPHIC *chemistry*, an art of dividing or resolving all the bodies in our power by means of all the instruments that can be procured, and that as well into integrant as into constituent parts, and joining these parts together again, so as to discover the principles, relations and changes of bodies, make various mixtures and compositions, find out the physical causes of physical effects, and hence improve the state of natural knowledge and the arts depending on it. *Shaw's* Lectures, p. 1. See the article CHEMISTRY.

PHILOSOPHIC *spirit of wine*. See the article WINE.

PHILOSOPHY (*Cycl.*)—By *philosophy* we mean the knowledge of the reasons of things, in opposition to history, which is the bare knowledge of facts; or to mathematics, which is the knowledge of the quantity of things or their measures.

These three kinds of knowledge ought to be joined as much as possible. History furnishes matter, principles and practical examinations, and mathematics compleat the evidence. *Philosophy* being the knowledge of the reasons of things, all arts must have their peculiar *philosophy* which constitutes their theory: not only law and physic, but the lowest and most abject arts are not destitute of their reasons, which might usefully employ

employ the time of the ſtudious. It is true, thoſe who call themſelves *philoſophers* and learned men have as yet done little towards forwarding the intelligence of arts: but we ſpeak not of what is done, but of what ought to be done.

One great obſtacle to the progreſs of arts and ſciences has been the neglect of practice in ſpeculative men, and the ignorance or contempt of theory in mere practical men. What chimeras and abſurdities the neglect of experience and practice has produced, need not be mentioned; the miſchiefs ariſing from a neglect of theory, are not ſo obvious: yet certainly it retards the progreſs of arts. All invention or improvement muſt be either caſual or rational, including analogy or inference from ſimilar caſes, under the term rational. Now altho' the foundations of arts have often been owing to ſome caſual diſcovery, as gunpowder or the loadſtone; yet is this not to be truſted to alone. Improvements do not always flow from this ſource, but rather from the reflexions of artiſts; and if theſe reflexions were rendered more diſtinct, more communicable and eaſier to be retained, by the proper uſe of ſigns and other *philoſophical* helps, great advantages might be expected: it being certain, that *philoſophical* knowledge is more extenſive, and more ſure in the application; and beſides, gives a pleaſure to the mind not to be expected from that which is merely hiſtorical.

It is to be obſerved, that the bare intelligence and memory of *philoſophical* propoſitions, without any ability to demonſtrate them, is not *philoſophy*, but hiſtory only. However, where ſuch propoſitions are determinate and true, they may be uſefully applied in practice, even by thoſe who are ignorant of their demonſtrations. Of this we ſee daily inſtances in the rules of arithmetic, practical geometry, and navigation; the reaſons of which are often not underſtood by thoſe who practiſe them with ſucceſs. And this ſucceſs in the application produces a conviction of mind, which is a kind of medium between *philoſophical*, or ſcientifical, and hiſtorical knowledge. The ingenious author of the Analyſt has gone ſo far as to ſuggeſt, that mathematicians have no other conviction of the truth of the doctrine of fluxions.

Philoſophy may be divided into three parts, intellectual, moral, and phyſical. The intellectual part comprizes logic and metaphyſics. The moral part contains the laws of nature and nations, ethics and politics. And laſtly, the phyſical part comprehends the doctrine of bodies, animate or inanimate. Theſe, with their various ſubdiviſions, will take in the whole of *philoſophy*.

Wolfius makes the three parts of *philoſophy* to be the doctrine of God, the human ſoul, and of bodies [a]. However, when he ſubdivides, and comes to treat the ſeveral branches ſeparately, his diviſions readily come under the three heads intellectual, moral, and phyſical, before mentioned. The doctrine of God and the human ſoul may be ranged under the ſame head metaphyſics, the notion of the divine nature being formed from that of the human ſoul, excluding limitations and imperfections [b]. [[a] *Wolf.*. Diſc. Prælim. Logic. ſect. 56. [b] *Wolf.*. Theol. nat Part. 1. ſect. 1059.]

We have ſaid that *philoſophy* is the knowledge of the reaſons of things. It may be aſked what is the reaſons of things, or what is the explication of phænomena or facts. An ingenious author tells us, that the explication conſiſts only in ſhewing the conformity any particular phænomenon hath to the general laws of nature, or, which is the ſame thing, is diſcovering the uniformity there is in the production of natural effects. This he thinks evident to whoever ſhall attend to the ſeveral inſtances, wherein philoſophers pretend to account for appearances. By a diligent obſervation of the phænomena within our view, we may diſcover the general laws of nature, and from thence deduce, tho' not demonſtrate other phænomena, all deductions of this kind depending on a ſuppoſition that the author of nature always operates uniformly, and in a conſtant obſervation of thoſe rules we take for principles; which we cannot evidently know. *Berkeley*, Princip. of Hum. Knowl. Sect. 62 & 107.

If we take a view of the ſeveral phænomena, and compare them together, we may obſerve ſome likeneſs and conformity between them. For example, in the falling of a ſtone to the ground, in the riſing of the ſea towards the moon, in coheſion and cryſtallization, there is ſomething alike, namely an union or mutual approach of bodies: ſo that any one of theſe, or the like phænomena, may not ſeem ſtrange or ſurpriſing to a man who has nicely obſerved and compared the effects of nature: for that only is thought ſo which is uncommon, or a thing by itſelf, and out of the ordinary courſe of our obſervation. That bodies ſhould tend towards the center of the earth, is not thought ſtrange, becauſe it is what we perceive every moment of our lives; but that they ſhould have a like gravitation towards the center of the moon, may ſeem odd and unaccountable to moſt men, becauſe it is diſcerned only in the tides; but a philoſopher, whoſe thoughts take in a larger compaſs of nature, having obſerved a certain ſimilitude of appearances, as well in the heavens as the earth, that argue innumerable bodies to have mutual tendency towards each other, which he denotes by the general name attraction, whatever can be reduced to that he thinks juſtly accounted for. Thus he explains the tides by the attraction of the terraqueous globe towards the moon, which to him doth not appear odd or anomalous, but only a particular example of a general rule or law of nature.

If, therefore, we conſider the difference there is betwixt natural philoſophers and other men, with regard to their knowledge of the phænomena, we ſhall find it conſiſts not in an exacter knowledge of the efficient cauſe that produces them, for that can be no other than the will of a ſpirit; but only in a greater largeneſs of comprehenſion, whereby analogies, harmonics, and agreements are diſcovered in the works of nature, and the particular effects explained: that is, reduced to general rules, which rules, grounded on the analogy and uniformneſs obſerved in the production of natural effects, are moſt agreeable and ſought after by the mind; for that, they extend our proſpect beyond what is preſent and near to us, and enable us to make very probable conjectures, touching things that may have happened at very great diſtances of time and place, as well as to predict things to come; which ſort of endeavour towards omniſcience, is much affected by the mind. *Berkeley*, Princ. of Hum Knowledge, Sect. 104, 105.

PHILYRA, in natural hiſtory, a name given to the ſubſtance of which ſome of the moſt antient books are written. It is the inner bark of the *tilia*, or common lime-tree. The emperor's library at Vienna has a book written by Tully, never yet publiſhed, which is written on this ſubſtance. *Munting.* de Plantis.

PHLEBOTOMY, *(Cycl.)* in ſurgery, the opening of a vein by a proper ſharp-edged and pointed inſtrument of ſteel, for letting out a proper quantity of blood, either for the preſervation or recovery of a perſon's health.

This appears not only to be one of the moſt uſeful, but one of the moſt antient operations in ſurgery, ſince we find by Hippocrates, Celſus, &c. that it was practiſed near three thouſand years ago. The operation is frequently performed in different parts of the body, as the hand, the foot, the forehead, temples, neck, tongue, penis, and other parts; yet it is moſt generally performed in that vein of the arm which lies near the joint of the cubit. *Heiſter*'s Surg p. 273.

In bleeding it ſometimes happens, that an artery is opened either inſtead of, or together with, the vein: an accident of this kind is attended with the utmoſt danger. An artery is known to be wounded when the blood ſpins out very forcibly from the orifice, and that by ſtarts or leaps, not in an even ſtream, and extends itſelf in a greater arch from the orifice to the baſin. The colour of the blood from an artery is alſo much more florid than from a vein; to which add, that on preſſing the finger on the veſſel below the orifice, the blood ſtarts out more violently than before; and ſtops, or at leaſt abates, on preſſing above the orifice; quite the contrary of what happens on the opening a vein.

In an accident of this kind, the ſurgeon ſhould have preſence of mind not to betray the caſe by his fears to the patient, or attendants: he ſhould obſerve whether the blood flows freely from the orifice, or whether it inſinuates itſelf in any conſiderable quantity between the integuments. If the firſt is the caſe, he muſt take a large quantity of blood away, even till the patient faints, perſuading the attendants, that the heat of the blood requires it; and while the patient is in his fainting fits, as the flux then ceaſes, he may commodiouſly dreſs and bind up the wound; and by this precaution hinder a freſh hæmorrhage or an aneuriſm. The ſurgeon muſt place ſome ſmall piece of money between the folds of the firſt compreſs; and on this place two, three, or more compreſſes, each larger than the other: and then bending the cubitus, apply two bandages in this manner, as after bleeding in the vein, only a little tighter; and lay a thick, long, and narrow compreſs over the artery, from the cubitus to the axilla and the patient muſt be warned to wear his arm in a ſling, pinned to his cloaths, for a fortnight, and refrain from all uſe of it. *Heiſter*'s Surg. p. 287.

If the blood from the wounded artery is found to inſinuate itſelf between the integuments, the orifice muſt be immediately compreſſed, and tied up as before directed; and the arm often inſpected, to ſee whether a bleeding within the integuments does not yet continue. The patient muſt be frequently bled in the other arm, and if a large quantity of blood ſhould be lodged from the wounded artery under the integuments, it will be neceſſary to open the integuments to diſcharge it.

It is too common an accident to find a nerve or tendon punctured in bleeding, and this is generally known to be the caſe by the patient's making a ſevere outcry at the time; and eſpecially if he complains afterwards of acute pains, and the limb begins to ſwell and be inflamed, convulſed, ſtiff, and extended as in the cramp: which ſymptoms, if not timely relieved, threaten convulſions of the whole body, a gangrene of the part, and even death in a ſhort time.

The beſt method to be taken in theſe accidents, is to firſt bathe the part with a mixture of oil of turpentine and ſpirit of wine, and then inveſt the whole arm with the diachalciteos plaiſter, melted down in oil of vinegar and roſes, retaining it on by the expulſive bandage; which beginning upon the hand, aſcends gradually by ſpiral turns to the top of the ſhoulder; by which means the impulſe of the blood on the part is not only much abated, but alſo the pain and inflammation much diminiſhed: and laſtly, the following cataplaſm ſhould be applied

to the arm, to compleat the cure: take of flour of barley and of bitter vetch, of each two ounces; chamomile flowers and melilot flowers, of each two handfuls; freſh butter, an ounce and half: boil theſe into a cataplaſm with ſoap ſuds, and apply them to the arm till the pain and other bad ſymptoms are removed. *Heiſter*'s Surg. p. 286.

PHLEBOTOMY *in the eyes.* There are ſeveral ways of performing this operation, but the beſt ſeems to be this. The patient being ſeated on a chair, and his head held in a proper poſture, a tranſverſe inciſion is to be made, with a fine lancet, upon the turgid ſmall veins in the corners of the eye, ſo as to open them or cut them quite aſunder. The eye-lids muſt be held apart with one hand, whilſt the veins are opened with the other; and ſome uſe a pair of fine ſciſſars for this purpoſe, inſtead of a lancet, and others elevate the veins with a crooked needle before they divide them: but in this operation the better way would be to make the needles with edges, that when the veins were thus elevated, they might divide them without the help of any other inſtrument. When the inciſion is made, the diſcharge of blood muſt be promoted by means of fomentation, with a ſpunge dipped in warm water; and if the diſcharge is not ſufficient, the inciſion may be repeated two or three times: but few patients can be brought to ſuffer this, and there is no practiſing it at all upon infants, becauſe they will not keep the eye ſteady. *Heiſter*'s Surg. p. 377.

PHLEGMASIA, a word uſed by ſome of the medical writers for an inflammation. Hippocrates alſo ſometimes uſes it to expreſs the violent heat in fevers.

PHLEGMON (*Cycl.*)—If the proximate cauſe of theſe tumors be enquired into, we ſhall find it generally riſes from too thick or viſcid a ſtate of the blood, ſtagnating in the anaſtomoſes of the ſmalleſt veins and arteries; ſo that the blood being propelled in larger quantities than can paſs thro' thoſe veſſels, it muſt of conſequence excite the ſymptoms that are the attendants of this tumor, and occaſion great diſorder at every part where ſuch ſtagnation is made.

No part of the body, whether external or internal, is perfectly exempt from this ſort of tumor, not even the bones themſelves; but it is more common in the fat and glands than elſewhere.

The cauſes of this ſtagnation of the blood are either external or internal.

Among the external, are all wounds, fractures, luxations, contuſions, punctures, by thorns and ſplinters, with a too great compreſſion of the veſſels, whether by too ſtrict a bandage, or by other means; each of which obſtructing the paſſage of the blood thro' its minute veſſels, either by dividing, bruiſing, compreſſing or diſtorting them, may give riſe to this tumor. And to this may be added, burns of all kinds, with too violent cold, the too great motion of the body, the external application of ſharp and ſtimulating ſubſtances to the ſkin, and others, which ſtop the pores of the ſkin, and impede the circulation of the blood.

Among the internal cauſes, are to be reckoned the too great acrimony of the blood, as in ſcorbutic habits, the blood's abounding in too great quantities, or being of too thick a conſiſtence, or, laſtly, its circulating in the body with too violent a motion; for by this laſt means, the groſſer particles of the blood are protruded, and wedged in, as it were, in the ſmaller veſſels, thro' which they cannot find a paſſage; and this is eſpecially the caſe, when a ſudden cold is given to the body from a ſtate of extreme heat. In ſhort, every thing will produce an obſtruction that makes either the particles of the blood too large, or the mouths of the veſſels too ſmall and narrow to receive them.

The reſolution or diſperſion of a tumor of this kind is only practicable when the tumor is of a milder kind; when it is in a ſound habit of body, and when the blood is not yet too viſcid, or too violent in its motion: but ſuppuration follows when the inflammation is more violent, the circulation more rapid; but yet the maſs of blood ſomewhat temperate and free from acrimony. That is, when the blood becoming more inſpiſſated, and its larger particles ſticking in the more minute veſſels, can find no paſſage; but the ſmall veſſels are burſt by the preſſure and impulſe of the obſtructed blood, ſo that their contents are extravaſated in the fat, fleſh, and adjacent parts. Upon this extravaſation, the more ſubtle and fluid parts of the blood putrefy, by means of the great heat, and become fœtid and acrimonious, and corrode the adjacent parts: the fluids thus changed or corrupted, are, by the ſurgeons, called matter or pus; and this is of ſeveral kinds, according to its conſiſtence and colours: it is either white, yellow, greeniſh, reddiſh, or party-coloured.

When the forementioned ſymptoms are much more violent, and the blood at the ſame time more acrimonious than it ought to be, this inflammation generally terminates in a gangrene: for in that caſe, the ſmalleſt arteries and veins are corrupted, burſt, and broke; and hence the adjacent parts are diſſolved and corrupted by theſe extravaſated acrimonious humors, and particularly the ſkin is very ſubject to be filled with puſtules, when its cuticle has been ſeparated, as in burns. The ſanies contained in theſe puſtules and elſewhere, is uſually termed ichor, and is generally of a pale reddiſh caſt, and ſometimes brown or livid, which is much worſe; for unleſs the patient in this caſe is timely aſſiſted, the ſymptoms of inflammation all go off, the tumor, reſiſtance, heat, redneſs, pain, and pulſation, gradually diſappear, and the limb becomes flaccid and cold; it afterwards turns pale, and becomes dead and inſenſible, and the inflammation creeps to ſome other part.

If this caſe be treated with medicines too hot, too aſtringent, cooling, fat, acrimonious, or narcotic; or if the parts be bound too tight, the fleſh quite dies, its paleneſs turns to a livid lead colour; and the incloſed ſanies finding no vent, becomes more acrimonious, and ſo greatly corrodes the adjacent parts, as to deſtroy all ſenſe and motion, and brings on an entire ſphacelation of the whole limb. But if the inflamed part be full of glands, and the blood very thick, glutinous, and tough, the ſmall veſſels are then ſtrongly ſtuffed up with it, and impacted together; and the parts loſing their ſenſation, become changed into a hard tumor, called a ſcirrhus. The cure of *phlegmons* is by diſperſion or ſuppuration: the methods for bringing on theſe, ſee under the heads DISPERSION and SUPPURATION. *Heiſter*'s Surg. p. 178.

PHLEOS, in botany. See the article PHEOS.

PHLEUM, in the Linnæan ſyſtem of botany, a graſs called *typh idea*, or cat's-tail graſs by Scheuhzer, which makes, with this author, a diſtinct genus of plants, the characters of which are: that the cup is a glume, containing one flower; it is bivalve, oblong, ridged, and compreſſed, and opens into a double-pointed ſummit; the valves are erect, hollowed, compreſſed, equal in ſize, and bearded; the flower is compoſed of two valves, ſhorter than that of thoſe of the cup, the outer one, which is the larger, ſurrounding the inner or ſmaller one; the ſtamina are three capillary filaments, longer than the cup; the antheræ are oblong, and divided into two at the ends; the germen of the piſtil is roundiſh; the ſtyles are two in number, ſmall, and bent; and the ſtigmata are plumoſe; the cup and flower incloſe the ſeed, which is ſingle, and of a roundiſh form. *Linnæi* Gen. Plant. p. 14.

PHLOGIDAUGIA, in natural hiſtory, the name of a claſs of inflammable foſſils, of a pure texture, and in ſome degree tranſparent.

Of this claſs are the ſulphurs, orpiments, zornics, and amber. They are by this name diſtinguiſhed from the *phlogiſcieria*, or inflammable foſſils, of a coarſe texture, and opake; ſuch as the ambergreaſe, jet, and aſphalta, and the ampelites and common coal. *Hill*'s Hiſt. of Foſſ. p. 399.

PHLOGINOS, the name of a ſtone found in Ægypt, and called by ſome *chryſitis*, from its colour, reſembling gold.

Pliny deſcribes it as reſembling the Attic oiſter, as the paſſage is uſually printed; and hence Agricola and ſome others have ſuppoſed he only meant the *oſtracites*, or foſſile oiſter ſhell, by this name, tho' the other name, *chryſiti*, could not well be applied to that body. Salmaſius has very well explained the paſſage, by obſerving, that as the antients have no where mentioned the Attic oiſter, the words probably were originally *Attic ochre*; the ſenſe is then plain, and the ſtone is only ſaid to be of a fine yellow, like gold; or the *Attic*, that is the brighteſt yellow *ochre*. It probably was an agate of the cerachates kind.

PHLOGISCIERIA, in natural hiſtory, the name of a claſs of foſſils, the characters of which are, that the bodies contained in it are inflammable, of a coarſe and impure texture, and not pellucid.

The word is derived from the Greek φλόγινος, inflammable, and σκίερος opake. The bodies of this claſs are divided into two general orders, and under thoſe, into five genera. Thoſe of the firſt order, are ſuch as are found looſe, and in detached maſſes: thoſe of the ſecond, ſuch as are found conſtituting whole ſtrata. The genera of the firſt order are, ambergreaſe, jet, and the aſphalta; and thoſe of the ſecond, cannel and common coal. *Hill*'s Hiſt. Foſſ. p. 411. See AMBERGREASE, GAGATES, ASPHALTA, AMPELITES, and LITHANTHRAX.

PHLOGITES, in natural hiſtory, a name given by Pliny and other authors to a ſtone, which, they ſay, had the appearance of flames of fire, bubbling up and riſing to ſeveral points within it. It is ſometimes called alſo *phlegonites*.

Some have ſuppoſed that the antients meant no more by this diſtinction, than to expreſs a fire colour lodged in the ſtone, and have meant it as a name for the opal; but as the Germans have at this time an odd ſtone among them, which they commonly call petrified flames of fire, it is poſſible the antients might have had the ſame ſtone, and called it by this name.

The abſurdity of petrified fire is too groſs to need refutation, but the whole that is meant by the name, ſeems to be, that the ſtone had ſome ſtrait and erect rays, of fire colour.

Pliny ranks the *phlogites* among the gems, but Sabinus and others place it among the larger ſtones: and we have from ſome parts of Germany, a ſpar, with radiations of a fiery red in a white ground, which looks as like flames as any thing one could expect in a ſtone; but whether this, or ſome other, be the ſtone called petrified flames of fire by the collectors of that nation, we are not aſſured; the name only having as yet come to us, without the ſubſtance itſelf.

PHLOGONIÆ, in natural hiſtory, the name of a claſs of foſſils, uſually included by authors with many others of a very different kind, under the general name *pyritæ*. Theſe are defined

fined to be compound, inflammable, metallic bodies, found in ſmall maſſes, and of determinately angular figures. Of this claſs of bodies there are three genera.

1. The *pyricubia*, which are *phlogoniæ* of a regularly cubic figure. 2. The *pyroctagonia*: theſe are *phlogoniæ* of an octohædral figure, or compoſed of eight planes. And, 3. The *pyripolygonia*: theſe are *phlogoniæ* of a dodecahædral figure, or compoſed of twelve planes. *Hill's* Hiſt. of Foſſ. p. 618, 619. See PYRICUBIUM, &c.

PHLOGUS, in botany, a name given by ſome of the antients to the ſeveral ſpecies of the *iris* and *gladiolus*. and by ſome to the *flammula jovis*, a ſort of clematitis, ſo called becauſe of the violent heat of its leaves to the taſte.

Theophraſtus mentions this in the ſame part of his work with the violet and other ſpring flowers, and thi, not becauſe they are allied to one another in their characters, but becauſe they all flower at the early time of the year. Pliny miſtakes the author's meaning in this ſo far, as to ſuppoſe that he placed it among the violets as a plant of that kind; and has accordingly mentioned it as a violet with a flame-coloured flower.

This plant ſeems to have owed its name *jovis flamma* to a miſtake of Pliny's, who copying Theophraſtus, and finding him mention this *phlogus*, or *phlogium*, and another flower, called *dioſanthos*, or Jove's flower, together, has ſeemed to blend the two names, and make out the word *flamma*, or *flammula Jovis*, between them.

PHLOMIS, in botany, the name of a genus of plants, the characters of which are theſe: the flower is labiated, conſiſting of one leaf; the upper lip is hooded, and the lower, over which this lies, is divided into three ſegments: the piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and ſurrounded with four embryos, which finally ripen into four ſeeds, of an oblong ſhape, contained in a pentangular cup, which is the cup of the flower.

The ſpecies of *phlomis*, enumerated by Mr. Tournefort, are theſe: 1. The ſhrubby *phlomis*, with a broad and roundiſh ſage-like leaf. 2. The ſhrubby *phlomis*, with a narrow and longer ſage-like leaf. 3. The round leafed purple-flowered ſhrubby *phlomis*. 4. The pointed-leaved purple-flowered ſhrubby *phlomis* of Portugal. 5. The purple-flowered clary-leaved *phlomis*. 6. The purple-flowered very white Spaniſh ſhrubby *phlomis*. 7. The herbaceous very white Spaniſh *phlomis*. 8. The taper *phlomis*, commonly miſtaken for a ſpecies of mullein, and called by authors *verbaſcum anguſtis ſalviæ foliis*, or the narrow ſage-leaved mullein, and the wild yellow mullein, with gaping flowers. *Tourn.* Inſt. p. 177.

PHLOMON *ſtephanomaticon*, in the botanical writings of the antients, a name given to the common white mullein. The upper part of the thyrſus, or ſpike of flowers of this plant, was frequently uſed in the garlands and coronæ of the antients; and it is named by Dioſcorides and others among the yellow flowers in general uſe on that occaſion.

It is remarkable, that Dioſcorides, tho' he mentions this plant in the claſs of garland herbs, among the elychryſa and other yellow flowered herbs, no where mentions it under the mullein, where he is deſcribing the characters and ſpecies of that plant. It ſhould ſeem from this, and from ſome other ſuch paſſages, where this author deſcribes the ſame plant twice without knowing it; or omits it in its proper place, and treats of it only occaſionally in ſome other, that he had not a perfect knowledge of the botany of his time: but that, like Pliny, he collected what he has left us from the works of other authors now loſt.

PHLYSIS, a term uſed by the antients to expreſs an eruption on the ſkin, from a redundance of humors.

PHLYZATION, a puſtule or inflammation on the ſkin, or the bliſters ariſing on it after being burnt or ſcalded with a hot liquor.

PHOCA, the *ſea-calf*, in the Linnæan ſyſtem of zoology, a diſtinct genus of animals, the characters of which are, that they have two paps placed near the navel, feet adapted to ſwimming, and have no ears.

There are two kinds of this animal: the common one, called the *ſea-calf*, which has its canine, or dog-teeth, encloſed like the others in its mouth; and the other, which ſome improperly call the *hippopotamus*, or ſea horſe, which has theſe teeth exſerted or thruſt out. *Linnæi* Syſtem. Natur. p. 36.

We have a draught of this animal in the philoſophical tranſactions, numb 469, by Dr. Parſons, who obſerves, that Aldrovandus, Johnſton, Rondeletius, and Geſner, have made ſeveral miſtakes in the figure of this creature, ſo as to convey no juſt idea of it.

Upon diſſecting one of theſe animals, the ſtomach, inteſtines, bladder, kidneys, ureter, diaphragm, lungs, great blood-veſſels, and pudenda, were like thoſe of a cow; the hairs of the whiſkers were very horny and clear; the ſpleen was two foot long, four inches broad, and very thin; the liver conſiſted of ſix lobes, each hanging as long and as lank as the ſpleen, with a very ſmall gall-bladder. The beaſt was long and flabby in its contexture in general, having a large foramen ovale, and very great columnæ carnoſæ. In the lower ſtomach were about four pounds weight of flinty pebbles, all ſharp and angular, as if the animal choſe them of that form for cutting the food. The uterus was of the horned kind, each of the cornua being thicker than the body or duct leading to them. The ovaria were very large, being granulated on the ſurface with the ova, under a very thin membrane; and the opening into the tubes leading to the cornua is a great hole.

The authors who have treated on this animal, are Ariſtotle, Pliny, Aldrovandus, Rondeletius, Geſner, Wolfgangius, and Johnſton. Phil. Tranſ Nº. 469.

This animal is viviparous, and ſuckles its young by the mammillæ, like quadrupeds; and its fleſh is carneous and muſcular. That diſſected by Dr. Parſons was ſeven foot and an half long, tho' very young, having ſcarce any teeth, and having four holes regularly placed about the navel, which in time become papillæ.

PHOCÆNA, in zoology, the name uſed by authors for the *porpeſſe*, diſtinctively from the dolphin, a fiſh very like it, and by many confounded with it. See DELPHINUS.

The *phocæna* is of a roundiſh, not flat body, growing gradually ſmaller toward the tail; and juſt at the root of the tail is a little flatted. Its noſe is long and pointed, and furniſhed with ſtrong muſcles; by means of which it is able to turn up the mud and ſand, to ſeek after ſmall animals. Its ſkin is ſmooth, and but thin: its back is of a duſky bluiſh hue, almoſt black in ſome of the fiſh; and from the middle of the ſides downwards, it is whitiſh: it has no gills, nor any apertures in the place of them; but in the middle of the upper part of its head, it has a ſpiracle, in form of a half moon, divided by a ſubſtance reſembling a coxcomb, into two noſtrils, which, as they run inward, join and make one canal, which opens within the mouth a little below the œſophagus. This canal is provided with muſcles, to keep it ſhut againſt the admiſſion or emiſſion of any fluid, but at the creature's pleaſure; and by means of this he diſcharges the water taken in with his food. Its eyes are ſmall: its auditory paſſages extremely minute: its teeth alſo ſmall: it has two fins on the breaſt, and one on the back: and its tail is ſlightly forked, and placed horizontally, not vertically, as in other fiſhes: its lungs are like thoſe of quadrupeds: it is common in many places, and ſometimes is ſtranded on the Engliſh coaſt: its fleſh is not at all valued. *Ray's* Ichthyol. p. 31.

PHŒNICOPTERUS, in zoology, the name of a very remarkable water-bird, called alſo *flammant* and *flamingo*.

It has extremely long legs, and an extremely long neck. Its beak is broad, and of a very ſingular figure; the upper chap being bent, depreſſed, and dentated; the lower, much thicker, and firmer. It is black at the end, and in the other part of a duſky blue. Its neck and body are white; the long flight feathers of its wings black, but the ſhorter feathers, which make the covering of the wings, are of a very elegant and bright red, whence the bird has its name: it is web-footed, tho' ſo remarkably long legged: it lives about waters, and feeds on fiſh: it is common in many parts of America, and is ſeen at times in many parts of Europe: it was well known to the antients, and its tongue was accounted a very great delicacy among the nice eaters of old times. See Tab. of Birds, Nº 46. *Ray's* Ornithol. p. 240.

One thing very remarkable about it is, that its beak is ſo long and crooked, that the whole head muſt be immerſed before the water can get into it. *Pitiſc* in voc.

PHŒNICOPUS *gallinula*, in zoology, a name by which ſome authors have called a bird, more uſually known by the name *tringa*. *Geſner* de Avib. See TRINGA.

PHŒNICURUS, φοινικουρος, in zoology, a name by which the antient naturaliſts called the *ruticilla*, or redſtart. See the article RUTICILLA.

PHŒNIX, (*Cycl.*) in botany, a name given by medicinal writers to the graſs called *lolium rubrum*, and in Engliſh, *ray-graſs*. *C. Bauhin.* p. 9.

PHOENIX is alſo the name given by Kæmpfer and Linnæus to a genus of plants, called by others *elate* and *katou-indel*. The characters are theſe: it produces ſeparate male and female flowers, in both the whole ſpatha ſerves for a cup: in the male the petals are three in number, and are of an oval figure, and concave: the ſtamina are three ſlender filaments, and the antheræ are very ſhort: in the female flower the germen of the piſtil is of a roundiſh figure: the ſtyle is ſhort and pointed, and the ſtigma is acute: the fruit is an oval berry, having only one cell; this contains one ſeed, which is of a bony hardneſs, and of an oval figure, with a deep longitudinal furrow reaching from one end to the other. *Linnæi* Gen. Pl. 513. Muſ Cliff, 12. Hort. Mal 3, 23.

PHOENIX, φοινιξ, among the antients, a muſical inſtrument not unlike the *cithara*. *Hoffm* Lex in voc. See the article CITHARA, *Cycl.*

PHŒOPUS, in zoology, a name uſed for two different birds; the one called by the Germans *brachvogel*, and the other the *whimbrell*, or *aquata minor*, the ſmall curlew of authors.

The firſt of theſe, or the *brachvogel*, is of a deep black colour, ſpotted with a yellowiſh and a reddiſh brown: its beak is long, ſlender, and black, and is moderately bent: its neck is grey, tending to reddiſhneſs towards the bottom, and its belly is white. Mr. Ray ſuſpects this not eſſentially to differ from the other, but the ſight of the bird alone can determine that. *Geſner* de Avib. *Aldrovand* de Avib. L. 20. c. 41.

PHOLAS, in natural hiftory, the name of a genus of fhells, the characters of which are thefe: It is an oblong multivalve fhell, compofed of five fhells, tho' in fome, improperly ac counted fpecies of this genus, only of two. It is fmooth in fome fpecies, in others rough, and in fome reticulated; in fome fpecies it fhuts clofe and even, in others it gapes always open.

Of the oblong fhells, ufually called *pholades*, and confifting only of two fhells, we meet with the following fpecies: 1. The fmooth *pholas*, of Rondeletius. 2. The fmooth nar rower *pholas*, of Aldrovand. 3. The wood-*pholas*, of Rumphius. 4. The fmooth mufcle-like *pholas*. 5. The finger-*pholas*, of Bonani. 6. The pale red and white *pholas*.

Of the oblong and irregular *pholades*, which confift only of two valves, we have the following fpecies: 1. The great American *pholas*. 2. The broad *pholas*, with the long trunk

Of the oblong irregular *pholas*, confifting of five valves, we have only one known fpecies, which is the *pholas* of Lifter. See Tab. of Shells, N°. 29 and Hift. Nat. Eclairc. p. 356.

The word *pholas* is derived from the Greek, and fignifies no more than any thing which is hidden; the name was given to this genus of fhell-fifh from their cuftom of making themfelves holes in earth, fand, ftones, or wood, and living hidden in them. Many being of opinion, that thefe fifh could not work themfelves into the fubftance of hard ftones, have thought that they were hatched in holes accidentally formed in ftones, and that the fhells naturally grew of fuch a fhape as was neceffary to fill the cavity. Nor is this the only error propagated concerning the *pholas*; for as all that was fignified by the name being only that the fhell was hidden in fome folid fubftance, whenever an author found a fhell-fifh of whatever kind thus buried in ftone, he defcribed it under the name of *pholas*.

There are many fpecies of the fhell-fifh, and thefe of feveral different genera, which thus hide themfelves in ftone; and thefe have therefore been called by different authors *pholades*; and hence it has been faid, that the *pholas* was in fome fpecies a bivalve, and in others a multivalve fhell. The true *pholas*, which Lifter has very well defcribed, is a genuine multivalve, being compofed of five pieces; but this is a very fcarce fifh, and feveral of the mufcles and of the chamæ being often found in ftone, they have all been called bivalve *pholades*; and fuch as have found the chamæ thus immerfed, and found them really to confift of only two fhells, have cenfured the authors of error who have defcribed the *pholas* as having five. Hift. Nat. Eclairc. p. 362.

All the fpecies of fhell-fifh which are found in ftone, have certainly been the means of making the holes in which they are found: the fact is inconteftible, but the means yet wholly unknown. Perhaps when fome accurate obferver fhall have an opportunity of examining the fifh alive, the myftery will be cleared up. All that we know at prefent is, that they are firft buried in the ftone while very fmall; fince the aperture on the furface of the ftone is ufually much fmaller than the diameter of the fhell contained within, and only ferves to admit the fea water, or to give paffage to the probofcis of the inclofed fifh.

The chamæ, which are frequently known among us under the name of the *pholas*, and common about our fhores, are often found in a foft ftone of the feptaria or ludus Helmontii kind; and as there is a great refemblance between this ftone and a hardened clay in its external appearance, many have fallen into an opinion of its being a petrified clay. On this principle it has feemed eafy to account for the ftrange phænomenon of the *pholades* or chamæ being found in it, fince it has been fuppofed that they made their way into it while in the ftate of clay, and that it afterwards became petrified or hardened into ftone while they were in it. But not to mention the error of the opinion of this fort of ftone being a petrified clay, or the abfurdity of fuppofing that fuch a petrifaction, were it made at all, could be effected in fo fhort a time as during the life of the fifh. It is eafy to anfwer this opinion by another obfervation, which is, that on the coafts of Italy it is not uncommon to find wrought pieces of hard marble, formed into pillars and other ornamental parts of building, in which are lodged the true *pholades*, as alfo chamæ and mufcles, in the fame manner as in our fofter ftones. It is not to be fuppofed that thefe pieces of marble were ever any thing elfe but marble; and we have an account from Woodward of certain columns of marble which were dragged up out of the fea, after their having been loft there but a few years before, and thefe were all full of *pholades*. If any thing could be wanting after this to prove the certainty of the fact, that the *pholades* make themfelves the holes they live in, it might be added that they are often found lodged in wood, as well as in different kinds of ftones; the bottoms of fhips being frequently pierced by them. There is an opinion among the vulgar, that the *pholades*, after a time, change into butterflies; but this is too abfurd to need a refutation. The fifh is very good to eat, and is taken in quantities on breaking the ftones; for they never live fingly, but many in the fame ftone.

In the memoirs of the academy of fciences it is faid, that the fhell of the *pholas* is compofed of three pieces, two of which are equal in fize and alike in fhape; and the third, which is vaftly fmaller than thefe, is placed near the fummit of the others, and fills up a little fpace, which they leave empty: this is ufually of the figure of a lozenge, one of the fharp ends of it coming in contact with the other fhells at their tops; but fometimes it is only pointed at both ends, and rounded in its intermediate part, and the external furface of it is ufually convex. The two large valves of the fhell are twice or three times as long as they are wide, and the cardo, which joins them, is placed near one end; they grow gradually fmaller to the other extremity, where they terminate in an oval. They are furrowed and channelled in the manner of a file, having many longitudinal ftreaks croffed by a great number of tranfverfe ones; thefe lines mark the age or different growths of the fifh, and their ridges are often befet with fmall points like prickles. The two valves of the fhell are ufually open, and are capable of expanding to a great width; but they do not expofe, or leave naked the body of the fifh on this occafion; for they are connected together by a membrane which opens to give them room, and forms with the two fhells a fort of cafe for the body of the fifh; and indeed this was the more neceffary, as the figure of the fhells is fuch, that they cannot ever perfectly clofe together, for when they come into contact in one part, another neceffarily remains open from their fhape. Mem. Acad. Par. 1712.

The holes in which the *pholades* lodge are ufually twice as deep, at leaft, as the fhell is long; and the figure of thefe holes is, that of a truncated cone, except that they are terminated at the bottom by a hollow rounded cavity, and their pofition is ufually fomewhat oblique to the horizon. The openings of thefe holes are what betray the *pholas*'s being in the ftone; but they are always very fmall, in proportion to the fize of the fifh. There feems to be no progreffive motion of any animal in nature fo flow as that of the *pholas*; it is immerfed in the hole, and has no movement except a fmall one toward the center of the earth; and this is only proportioned to the growth of the animal. Its work is very difficult in its motion, but it has great time to perform it in, as it only moves downward, finking itfelf deeper in the ftone as it increafes itfelf in bulk. The part by means of which it performs this, is a flefhy fubftance placed near the lower extremity of the fhell; it is of the fhape of a lozenge, and is confiderably large in proportion to the fize of the animal; and tho' it be of a foft fubftance, it is not to be wondered at that in fo long a time it is able, by conftant work, to burrow into a hard ftone. The manner of their performing this may be feen by taking one of them out of the ftone, and placing it upon fome foft clay; for they will immediately get to work in bending and extending that part allotted to dig for them, and in a few hours they will bury themfelves in the mud in as large a hole as they had taken many years to make in the ftone. They find little refiftance in fo foft a fubftance, and the neceffity of their hiding themfelves evidently makes them haften their work. The animal is lodged in the lower half of the hole in the ftone, and the upper half is filled up by a pipe of a flefhy fubftance and conic figure, truncated at the end: this they ufually extend to the orifice of the hole, and place on a level with the furface of the ftone; but they feldom extend it any farther than this. The pipe, tho' it appears fingle, is in reality compofed of two pipes, or at leaft it is compofed of two parts feparated by a membrane. The ufe of this pipe or probofcis, is the fame with that of the probofcides of other fhell-fifh, to take in fea water into their bodies, and afterwards to throw it out again. In the middle of their bodies they have a fmall green veffel, the ufe of which has not yet been difcovered; this, when plunged in fpirit of wine, becomes of a purple colour; but its colour on linnen will not become purple in the fun like that of the murex; and even if it would, its quantity is too fmall to make it worth preferving. Mem. Acad. Par. 1712.

The true or multivalve *pholas* is compofed of two large fhells, two other fmall ones at the back, and one long narrow and crooked one at the cardo. The three fmall fhells always fall off as foon as the creature is dead; hence we ufually fee the true *pholas*, with only two fhells, in cabinets, and hence fome have called it a bivalve, and others a trivalve fhell, having found one of the three other valves. Some alfo pretend, that the Englifh *pholades*, befide the five pieces already mentioned, have another, which ferves as an operculum. Many are of opinion, that the *pholades* bore their way into the ftones, by means of their rough fhells, but Bonani is of opinion, that they do it with certain teeth. *Lifter*'s Hift of Animal. Engl. p. 172. *Aldrovand* de Teftac. l 3. *Bonani* Recreat. Ment. et Oculi. p. 36.

PHOLIS, in natural hiftory, the name of a genus of foffils of the clafs of the gypfums or plaifter ftones, the diftinguifhing characters of which are, that the bodies of it are confiderably hard, compofed of fomewhat broad particles, and of a bright cryftalline luftre.

The word is derived from the Greek φολίς, a fcale, or fmall flake, from thefe bodies being compofed of particles of that form.

The ſpecies of this genus are the moſt valuable of all the gypſums, as burning to the beſt and fineſt plaiſter, but ſo far as is yet known there are but two of them. The fine plaiſter ſtone of Montmartre in France, called by us *plaiſter of Paris ſtone* and *Parget*; and the other the coarſer and ſomewhat reddiſh kind, common in many parts of England, and called *hall plaiſter*. *Hill's* Hiſt. of Foſſ. p. 112. See the article PARGET.

PHOLIS, in zoology, the name of a ſmall anguilliform fiſh, the back of which is brown, the belly white, and the whole back and ſides ſpotted, and the ſkin ſoft and not covered with ſcales, but with a tough mucilaginous matter like the eel. This moſt of all approaches to the *alauda*, and tho' uſually ſomewhat larger, yet Mr. Ray doubts whether it really differs from it in any thing eſſential; its great diſtinction being its colour, which tho' a very obvious, is a very precarious one. *Rondelet.* de Piſc. p. 20. *Ray's* Ichthyography, p. 135.

PHOLLIDES, a word uſed by the antient phyſicians for ſoft and fungous tumors of the legs, ſuch as thoſe of people in an anaſarca, or leucophlegmacy.

PHONASCI, in antiquity. See PHONASCIA, *Cycl.*

PHORBÆA, or PHORBEIA, in the muſic of the antients, a name given to a ſort of *frenum* or *bandage*, applied to the mouths of people who played on the pipe.

It was a ſort of leather band, which went firſt a-croſs the forehead, then behind each ear, and from thence making one or two turns round the head, it paſſed over the mouth, where its office was to reſtrain the lips from emiting too much breath at once, and cauſe them to diſcharge only juſt ſo much as would ſerve to inflate the pipe.

Simonides deſcribing the trial of ſkill between Marſyas and Apollo, mentions this *phorbeia* or *capiſtrum*, and ſome antique gems yet remaining among us, have the figure of a Marſyas's head, with the *phorbeia* upon it.

By the different ſtructure of the *phorbeia*, as expreſſed on the different coins, we find, however, that there were two ſpecies of it, the one was leſs complex, conſiſting only of a perpendicular piece down the cheek, and a tranſverſe one, running a-croſs the lips, and covering the whole orifice of the mouth, only leaving a hole cut thro' it, at which the mouth-piece of the pipe was to be put in. The other conſiſted of ſeveral bandages, as at firſt deſcribed, and the lower tranſverſe piece of theſe did not come over the mouth, but only bore up the lower lip, in a forcible manner, againſt the upper. The old Greek writers diſtinguiſhed theſe by two different names added to the original word *phorbeia*; the firſt, or ſimple one, was called *monomeres*; and the other, or more complex one, *diemeres*: they were both called alſo by Soranus, and others, *epideſma*, and ſometimes ſimply *deſma*. *Soranus* de Epideſmis.

PHORIMOS, a name given by ſome authors to *roach alum*. See the article ALUM.

PHORINE, a word uſed by ſome authors to expreſs the ſkin of a hog; ſome alſo underſtand it to mean a ſkin of any kind, extending it even to the human cutis.

PHORMIX, among the antients, the ſame with *cithara*. See the article CITHARA, *Cycl.*

PHORMORAPHIS, in the materia medica, a name often uſed by the later Greek writers, and generally looked on as one of their unintelligible words, or the name of ſome drug not known at this time.

If we may gueſs at the reſt of their unintelligible words, however, by this, it is probable that ſomething might be done toward the explaining and underſtanding them, by conſulting the other medical writers neareſt their times, and particularly the Arabians.

Aviſenna mentions the drug called *carpeſium*, or *carpeſia*, which, he ſays, was a common ſubſtitute, in his time, for cinnamon. Galen alſo tells us, that the ſame uſe was made of the *carpeſium* in his days; they add deſcriptions of the drug, by which it appears probable, that it was either the young ſhoots of the cubeb tree, or of ſome ſuch ſhrub. The later Greek writers generally copy their accounts of things from theſe, and they give exactly the ſame deſcription of the *phormoraphis* as theſe do of the carpeſia: its uſe, as a ſubſtitute for cinnamon, is alſo mentioned by them. And upon the whole it appears, that it was the name the later Greeks gave to the *carpeſium*, or *carpeſia*, of their predeceſſors. It is to be obſerved here, that there is another very different ſubſtance given in the old Greek writers under the name of *carpeſium*; and this word is ſometimes written *carpeſium* and *carpeſia*. This was a gum reſembling myrrh in ſmell and colour, but of a poiſonous nature: the *carpeſia* here mentioned was, on the contrary, an aromatic medicine. See CARPESIA.

PHOS, a word uſed by ſome medical writers to expreſs a diſtemperature of the eye, in which there is ſeen a black circle wholly ſurrounding the pupil.

PHOSCAS, in zoology, the name of a freſh-water fowl of the duck kind, and of the ſize of the common wigeon. Its body is remarkably flat; its beak and legs are blue; its head and neck are of a browniſh colour, variegated all over with numerous triangular black ſpots; and on the top of the head theſe ſpots are larger than elſewhere, and are of a ſomewhat greeniſh hue; the back, wings, and tail are of a duſky brown, but the edges of the feathers are pale or whitiſh; the wings are variegated by two long white ſtreaks; the breaſt and ſides are of the ſame colour with the back, but paler; and the belly of a fine white, but with a few duſky ſpots under the tail. *Ray's* Ornithol. p. 289.

PHOSPHORIA, φωσφορια, in antiquity, a feſtival in honour of Phoſphorus or Lucifer. *Potter*, Archæol. Græc. T. 1. p. 436.

PHOSPHORUS (*Cycl.*)—*Phoſphori* may be divided into ſeveral kinds; ſome ſhine of themſelves naturally, as the glow-worm and dates; or adventitiouſly, as the fleſh of animals, which moſt probably ariſes from a degree of putrefaction, ſometimes too ſlight to be obvious to our ſenſes. Other bodies become luminous by attrition, heat, the free action of air; and laſtly, by imbibing and retaining the rays of light. Thoſe bodies that are luminous by attrition, are, amongſt others, ſome diamonds, and the hairs of animals; by heat, ſeveral ſorts of gems, and mountain cryſtals; from the free acceſs of the air, the *phoſphori* of Kraft and Homberg; from the aſpect of light, the Bolognian luminous ſtone, the preparation by Chriſtian Adolphus Baldwin, of chalk diſſolved in ſpirit of nitre, as well as ſeveral others diſcovered by the late Monſieur du Fay, who found, that whatever ſubſtances would by calcination be converted into a calx, or whoſe concrete, from a ſolution in the acid of nitre, would bear fire enough to become red-hot, theſe bodies were adapted to imbibe and retain light.

The greateſt number of *phoſphori* are of the laſt mentioned kind. Some of theſe are natural, others artificial; but of theſe laſt the preparation is ſo ſlight, as not to change the nature of their conſtituent parts.

The natural *phoſphori* are either foſſile, vegetable, or animal. The foſſile are, though very different in degree, ſome ſorts of earths, white ſand, lime ſtones, ſtalactites, and ſeveral other figured ſtones, iſland cryſtals, flints, ſome ſpecies of agates, white arſenic; but no ſort of metals, metallic or ſulphureous bodies, as jet, amber, except the before-mentioned arſenic. On the other hand, ſalts imbibe light, provided they are diveſted of every metallic principle; otherwiſe not, though as pellucid as poſſible. For this reaſon none of the vitriols will imbibe light; but other ſalts will, tho' with a conſiderable difference as to quantity; for ſal gem and rock ſalt imbibe very little; ſea ſalt, if dry, and in cryſtals, much more; and in like manner, ſal ammoniac. ſal catharticum and nitre yet more. This power is weak in the natron of the antients, and alum; but brighteſt of all in borax.

In the vegetable kingdom we find very few *phoſphori*; that of dry rotten wood is weak and not laſting; it appears chiefly upon the edges and inequalities of the ſurface. But this is moſt remarkable in the rotten wood of the fir-tree, and ſome others, where, in the dark, you ſee ſhining ſpots as big as tares; whereas in full light the whole ſurface appears alike. Some few barks are luminous, but not conſiderably ſo; but no fruits, ſeeds, or their meals. Cotton and the cryſtals of tartar, appear very bright, but fine loaf ſugar appears the moſt luminous of all, both without and within: gums and reſins retain no light.

There is a vaſt variety of *phoſphori* in the animal kingdom, ſuch as the bones and teeth; to theſe may be added the ſhells of fiſh, egg-ſhells, the human calculus, bezoar, and in whatever parts of animals the terreſtrial principle is very predominant. But where there is a conſiderable quantity of oily matter, as in the hoofs, horns, and feathers, no light is manifeſt.

Beccari propoſes ſome queries concerning the natural *phoſphori*, of which the firſt is, In what and how great a light the object ought to be placed? He tried different *phoſphori* in different degrees of light, and found them imbibe moſt light from the ſun itſelf; next in quantity when the ſky was clear; and the leaſt in foggy weather. Theſe experiments ſhould be made in the open air, and not in a houſe with the glaſs-windows ſhut; becauſe many bodies appear luminous when the light has come directly to them, which will not have that appearance when the light has paſſed through the glaſs. He laſtly tried what light they would imbibe from very bright flame, and found that alabaſter itſelf, which is ſaturated more than any ſubſtance by the ſun's rays, imbibed exceedingly little. The next query is, How long theſe bodies ſhould remain in the light to be ſufficiently ſaturated? Four or five ſeconds were found the utmoſt length of time required for that purpoſe. The other query is, How long the received light will continue in theſe *phoſphori*? It does not laſt the ſame time in all; but continues more or leſs, from two ſeconds to eight, in proportion to the ſtrength of the *phoſphorus* and the quantity of light received.

Phoſphori are, it is well known, often produced by art; ſome are made by the maceration of plants alone, and without any fire; ſuch as thread, linnen cloth; but above all paper. The luminous appearance of this laſt is greatly increaſed by heat. This is confirmed by two experiments; the firſt is, by expoſing the paper, ſpread upon an iron-grate to the naked fire, yet not near enough to ſcorch it, and then laying a warm brick thereon to retain the heat; by which means it was obſerved, that where the paper was not ſkreened by the iron grate, it was moſt luminous; ſo that by the lights and ſhades you might diſtinguiſh in the dark the image of the iron-

iron-grate a confiderable time. The other experiment is, the application of the paper to a plate of warm brafs; from which, when in the dark, you might very eafily, by its being lefs luminous, diftinguifh the margin of the paper that had not been warmed by the brafs. The forementioned author takes notice alfo of thofe *phofphori* which become fo by the affiftance of fire; but the fire here fpoken of is not great enough to diffolve their conftituent parts, but only fuch as may affect the external parts of their texture, and that but gently; fo that the procefs here mentioned is only drying or roafting. For it is not the watry or the faline parts in bodies which are torrified; but the oleaginous, wherewith many vegetables, and moft animals abound. The white flefh of animals, fuch as that of chickens, becomes a *phofphorus* by roafting, as well as the tendons; and whatever parts of animals become glutinous by boiling, fuch as carpenters glue, ifing-glafs, &c. to thefe may be added cheefe. Bones, though they imbibe light without any preparation, have that property in a much greater degree when burnt, and their luminous appearance is much more lively. But roafting has not this effect upon feathers, hoofs, horns, or whites of eggs. The fame operation which produces feveral *phofphori* from the animal kingdom, gives alfo feveral from the vegetable. Thus, by gently toafting gums, as myrrh, gum tragacanth, and others, they appear luminous tho' different in degrees; and this light is clear in proportion to the gentle evaporation of their aqueous parts. By this treatment nuts of every kind, pulfe, corn, coffee-berries, meal, bread, and wafers, alfo become *phofphori*. Turpentine, amber, and fome refins, require more fire before they imbibe light; fo that you muft diveft them of their acid, and their light etherial oil, to make them appear luminous. But here great care muft be taken that they boil no longer than from being white they turn yellow; for if you proceed longer, your labour is loft. Thofe *phofphori* produced by torrefaction, foon lofe their power, which, perhaps, neither time nor a thorough diffolution of their parts can deprive the natural ones of. In general, as long as the *phofphori* gained by torrefaction, preferve their power, their light is more fharp and ftriking, but the natural more weak. Thofe that are gained by calcination, and Baldwin's *phofphorus*, feem to poffefs both the ftriking light of thofe gained by torrefaction, and the weaker light of the natural *phofphori*: the laft they preferve a long time, but the former is loft by degrees much fooner. The well calcined afhes of plants, or rather their terreftrial parts remaining after the folution of their fixed falts by wafhing, and neutral falts, continue *phofphori* after many years: fo that, as far as we can judge, the luminating power which is gained by calcination, tho' not fo intenfe, continues perpetual; whereas that gained by torrefaction always decreafes, and in a very little while is no longer vifible. Some even by this method, continue to imbibe light much longer than others. Gum arabic, which continues longeft, lafts fix days; bread not one, and coffee only a few minutes. However, at any time, by a frefh torrefaction, you may recover thefe languid *phofphori*; in which property they have great likenefs to the Bolonian ftone, and other *phofphori* prepared by art. The *phofphori* gained by torrefaction, as well as that of Bolonia, will not imbibe light while they are warm; and this laft does not appear fo luminous when firft prepared, as when it has been fo for fometime.

The natural *phofphori* do not differ only in the before-mentioned particulars, but alfo in the colour of the light itfelf. The light of the natural generally appears either perfectly bright, or fomewhat inclining to yellow; the artificial produces a red, and fometimes a brown light; but there are fome exceptions to both thefe rules. From thefe different appearances it may be conjectured, that there are two forts of fire arifing from different principles; *viz.* that in torrified fubftances from a fulphureous, and that of the natural from a terreftrial principle. In obferving a piece of lapis tutiæ, that was rough and unequal on its convex fide, but fmooth and fomewhat polifhed on the concave, Beccari, to his great furprife found, that the rough fide was luminous, and the fmooth one not: being very defirous of inveftigating the caufe of this appearance, he remembered that fome polifhed marbles did not imbibe light, or very little, and that at their edges; but having loft their polifh, they did admit and retain it. He therefore conjectures, that bodies, according to the difpofition of their furfaces for the reflection of the light, either fuffer or prevent its entrance into them. If this pofition hold good in the reflection, Why fhould it not with regard to the refraction? The fame author produces two experiments, which he apprehends not foreign to the prefent purpofe. Expofing a glafs-bottle full of well water to the light, and, as foon as poffible, obferving it in the dark, it was found to have imbibed no light; upon pouring into it fome oil of tartar, it became turbid and whitifh, from the well-water being ufually impregnated with calcarious matter. Upon obferving it then in the dark, after having been expofed as before, it retained enough of a pale light to diftinguifh the fhape of the bottle. In a bottle of rain water he diffolved fome talc; which ftone, by rubbing, will diffolve in water as falts do, without rendering it opaque; to this folution he added oil of tartar, and this mixture was luminous as the preceding. He therefore concludes, that fo long as earthy corpufcles are very fmall, feparate, and agreeing in their furfaces with the water in which they float, they readily tranfmit the light they receive; for which reafon 'tis impoffible they fhould retain light enough to appear luminous in the dark. But by the affufion of the faline principle, the earthy corpufcles unite with the water and falt; and from the union of thefe principles the mixture grows thick, whereby the ready tranfmiffion of the light is prevented; fo that if this mixture is without colour, or any thing metallic, the light will be ftopped long enough to be vifible in the dark. But if, inftead of oil of tartar, you add fugar of lead, the mixture will be turbid, but retain no light. In thefe two experiments the water becomes a *phofphorus*. Gems, cryftal, and glafs, whether whole, or powdered ever fo fine, retain no light; fo that neither their tranfparency nor whitenefs contribute to their becoming luminous in the dark. Of feveral diamonds in all appearance perfectly the fame, fome were very luminous, others not at all. Of many opaque fubftances, whether rough, polifhed, or finely powdered, fome were luminous, others not: fo that it appears that not only the external, but the internal texture of bodies alfo, may conduce fometimes to their being luminous.

Almoft all bodies, by a proper treatment, have that power of fhining in the dark, which, at firft, was fuppofed to be the property of one, and afterward only of a few. How this is brought about is not eafy to folve. If we fuppofe with fome, that the light from a luminous body, enters and abides in the *phofphori*, we fhall find fomewhat new to admire in light itfelf. It is no new opinion, that this fluid confifts of very fine particles, which are continually darted forth from a luminous body in all directions, with a very great velocity: but it has by no body been laid down hitherto, that thefe particles are not diffolved by the violence of their agitation, not difperfed, nor immediately ceafe to exift; but fubfift ftill, and adhere to what bodies come in their way, as heat does. If therefore the particles of light are not diffolved as foon as they are emitted from a radiant body, but continue fome time, what elfe is required but that we allow its atmofphere to every lucid appearance? If the *phofphori* fhine with a borrowed light, but not with their own, and that only when put in motion, and fired by the rays of a fhining body, which fome experiments feem to confirm, then other new doctrines will arife. There muft be then a hidden, a fecret principle in bodies, to be lighted up by this moft fubtle fire. There will be in the univerfe a certain perpetual fire from thefe *phofphori*; the matter of which, tho' conftantly diffipated by burning, does not wafte enough to be obvious to our fenfes. See Phil. Tranf. N° 478.

PHOSPHORUS *of urine*. The fuccefsful method of making this famous fubftance is this: evaporate any quantity of frefh urine over a gentle fire, to a black and almoft dry fubftance; then, with two pounds thereof, thoroughly mix twice its quantity of fine fand; put the mixture into a ftrong coated retort of ftone, and having poured a quart or two of water into a large receiver with a long neck, join it to the retort, and work it in a naked fire: let the heat be fmall for the two firft hours, and then increafe it gradually to its utmoft violence, and continue thus for three or four hours; at the expiration of which time there will pafs into the receiver a little phlegm and volatile falt, much black fœtid oil, and laftly, the matter of the *phofphorus*, in form of white clouds; which will either ftick to the fides of the receiver, like a fine yellow fkin, or elfe fall to the bottom, in form of a fmall fand. Now let the fire go out, but take not away the receiver before it is cold, for fear of fetting the *phofphorus* on fire by admitting the air. Take out the matter of the *phofphorus*, and put it into a little tin ingot mould, along with water; heat the mould to make the matter all run into a mafs, then add cold water, till it is congealed into a folid mafs like bees-wax; cut this into long flender pieces, which put into a phial, and fill it up with water, and then cork it clofe. *Shaw*'s Lect. p. 403.

This *phofphorus* is nothing but the animal fulphur. Now all animals, on which experiments have been made, are found to contain more or lefs of the phofphoreal principles; fome infects conftantly fhine, or emit light, in the open air; many forts of fifh are luminous, if expofed to the air a fhort time; nay, even the bubbles of the fea water appear like fire in the dark: fome quadrupeds have been obferved to emit light on very flight friction of their hair, as the necks of horfes, the backs of cats, and the like; and there are many inftances in our own fpecies of many parts of the body appearing luminous, and even of the exhalations from it adhering to the cloaths, caufing them to fhine likewife. We have feveral curious obfervations relating to this fubject in the Phil. Tranf. N° 476. p. 444, 445, 456, 457, &c.

Upon this principle of *phofphorus* exifting in animals, fome attempt to explain the caufe of thofe accidental accenfions or burnings which have happened to fome of the human fpecies, as that of the lady at Cefena in Italy, the carpenter in Hampfhire, and the woman lately at Ipfwich. It feems moft probable, that they were all fet on fire by lightening. It may be faid, many are ftruck by lightening, but not fet on fire. But it is to be remarked, that the lady at Cefena had charged all

all her pores and abforbent veffels with a great quantity of camphor. The woman at Ipfwich had drank plenty of gin; which circumftances muft greatly promote the kindling the *phofphoreal* fire in them: and as this pabulum was conveyed into the moft minute capillary veffels, it might produce an almoft inftantaneous deflagration and diffolution of all the folid containing parts. Phil. Tranf N°. 476, p. 447. feq.

Ammoniacal PHOSPHORUS, in chemiftry, the name of a *phofphorus*, compofed of fal ammoniac and lime, which Mr. Homberg firft difcovered.

The method of preparing it is this: take one part of fal ammoniac in powder, and two parts of lime extinguifhed by lying in the air: mix them exactly together, and fill a crucible with the mixture; fet it in a fmall melting heat. As foon as the crucible grows red hot, the matter in it will melt, and it muft be ftirred with an iron rod, left it fwell over the edges of the crucible: as foon as the whole is melted, pour it into a copper bafon; it will appear of a greyifh colour and vitrified, and if it be ftruck upon with any hard body, there will be feen a fire all over the place where the blow was given. As this matter is brittle, however, and the fame mafs will not ferve often for the experiment, the beft method is to dip iron rods in it while melting, and thefe will be covered with the matter, and will anfwer the purpofe eafily and often. Mem. Acad. Par. 1693.

Antimonial PHOSPHORUS, in chemiftry, the name of a fubftance having the qualities of the *phofphorus* difcovered by Mr. Geoffroy in his experiments on antimony. This gentleman had prepared a foap from pot-afhes, quick-lime, and oil, with which he made feveral experiments on antimony; among others he was defirous, by means of this, to reduce fome diaphoretic antimony, which he had before made from two parts of the regulus of antimony, and three parts of nitre; but inftead of the reduction which he was labouring after, his operation afforded him a much more fingular phænomenon: the refult of them being a *phofphorus*, which he had never thought of; a matter, which after having remained perfectly quiet while clofe ftopped down, took fire as foon as ever it was expofed to the air; and that with a violent detonation, and darting every way a fhower of fire.

It is eafy to fee, that there are in the preparation all the requifites for fuch an effect; nitre, charcoal furnifhed by the burnt foap, and fulphur both from the foap and from the regulus of antimony; and to all thefe, a fort of calx, either from the foap, or from fome earthy parts of the antimony. It is eafy to conceive, that all thefe fubftances coming to a mixture together, fhould be ready to catch fire and blaze upon a proper application; but it is not lefs difficult to account for this effect's being produced merely by the air, after the whole had been for a long time in a ftate of reft.

The method of preparing this new fpecies of *phofphorus* is this: Mr. Geoffroy mixed two ounces of his foap with one ounce of this diaphoretic antimony; this mixture being put by little and little into a red hot crucible, took fire, and fwelled very much. After it had done flaming, the mafs fubfided, and became a red or fire-coloured fubftance, of an even furface, but ftill throwing up a vaft quantity of bluifh-green luminous vapours: and all this regularly happened on every frefh throwing in of the matter, without the leaft variety. When the whole quantity was thrown in, and had ceafed to give any flame or luminous vapour, it remained in the crucible in the form of an inverted mufhroom, being hollow, very porous, and of a black colour. When the crucible was taken out of the fire, the edges of this fubftance were beaten down into the middle, and the whole covered with an ounce of frefh foap. When this laft foap was burnt, and a fmall bluifh flame appeared upon the furface of the mafs, the crucible was covered with a lid, and a large quantity of charcoal laid upon it, and the fire blowed up very brifkly, by an hundred blafts of the bellows, or thereabouts; but notwithftandig the fiercenefs of the fire, there was no fluid fcoriæ formed, but the whole mafs remained fpungy and porous. The fire was then fuffered to go out, and the crucible placed in a corner of the elaboratory at reft for five hours. In the evening, when the crucible was perfectly cold, Mr. Geoffroy went to examine the matter, and a fervant went to uncover the mafs, by removing its furface with an iron inftrument; but the moment the air was admitted, the whole mafs took fire, burning with a very confiderable noife, and darting its flames every way to a great diftance.

Mr. Geoffroy repeated the procefs feveral times, and always with the fame fuccefs, whether he ufed his own diaphoretic antimony, or that made in the common manner. The great caution to infure the fuccefs, feems to be the taking care of not carrying the fire too far before the addition of the laft quantity of foap. Mem. Acad. Scien. Par. 1736.

Aquatic PHOSPHORUS, a name given by Dr Leigh, in his hiftory of Lancafhire, to a water found near Wigan in that county, which takes fire on holding a lighted candle to it. It is not properly the water, however, that takes fire in this cafe, but a fteam which burfts out of the ground with it. The author alfo calls it a fulphurated water; but that very improperly, for it contains no fulphur, but only iffues out in company with this bituminous vapour.

PHOSPHORUS *of the bearne-ftone*, in natural hiftory, is a name given to a ftone, (which, when heated, becomes a fort of *phofphorus*) from the place where it is found; as the famous one of Bologna is called alfo from its native region.

The *bearne-ftone* is of a moderate hardnefs, confiderably pellucid, and ufually colourlefs, or whitifh, tho' fometimes with a tinge of green, yellow, or fome other colours: it is compofed of numbers of plates, or flakes, laid one over another, in the manner of the ifland cryftal; and therefore, like that body, is plainly a fpar. It breaks into feveral faces, and has different angles; but of a fomewhat determinate meafure, the acute ones being of fixty degrees, and the obtufe ones of 120. Mem. Acad. Par. 1724.

This ftone, when heated at one of its angles with the flame of a lamp or candle, fplits by means of the flame's infinuating itfelf into the interftices of the plates that are lefs firmly united; and thefe feparate, and fome fragments ufually fly off with confiderable violence. One of thefe pieces carried into an obfcure place, appears furrounded with a blue flame, which lafts about a minute. And it is to be obferved, that thefe pieces which fly off, have all the fhape of an irregular pyramid, with an uneven bafe. If this ftone be put into a crucible, and furrounded with coals, it becomes a very beautiful *phofphorus*. The whole bottom of the crucible is feen, even tho' it be in broad day light, fhining with a bright and beautiful blueifh white; and if it be carried into a dark place, the light is feen much more beautifully. If, after it is cold, it be again heated in a crucible, in the fame manner it fhews the fame bright appearance. After this, if it be tried a third time, it does not fhine at all. According to all thefe phænomena, the effects of fire upon this ftone feem to depend on a fulphur contained in it, probably of the fame nature with that which enters the compofition of the metals. This may, by means of a heat, fuch as that given by the candle or in the crucible, difengage itfelf fo far from the body of the ftone as to take fire; and when it has burnt fo long as to confume itfelf, the luminous property of the ftone feems to ceafe.

The coloured gems are cryftals of a peculiar kind, tinged with the fulphurs of metals: this fulphur gives them their colour, and confequently it ought to give them the properties of the *bearne-ftone*, if it were not too fixed to be diffipated in the fame eafy manner, and to take fire in the diffipation. And it appears on trial, that the baftard emeralds of Auvergne and other places, the matrix of the amethyft, the fragments of fome of the accidental jafpers, the jacynths, and fome fort of rubies, are all *phofphorufes* of the nature of the *bearne-ftone*, but with different degrees of brightnefs. The mother of the emerald, the yellow jafper, the water fapphire, the malachite, the opal, and the garnet, have none of them any of this property. Mem Acad. Par. 1724.

Since the fame fulphurs which take fire in the *bearne-ftone*, are what give colour to thefe other ftones, it fhould feem, that thofe which are not of this *phofphorus* kind, nor give a light after being heated, fhould not lofe their colours in the fire; and this is found to be true in the garnet, which does not lofe any part of its colour, nor is it at all luminous; whereas the hyacinth, and fome of the jafpers and other ftones, which lofe a part of the colour, not the whole, in the fire, become alfo in part luminous, or more fo, in degree, according to the quantity of colour which they lofe. This, however, is no certain rule, fince the mother of the emerald, the topaz, and fome other ftones, lofe all their colour, and yet are not at all luminous. The reafon of this feems to be, that the fulphurs are driven out of thefe ftones fo flowly, and in fuch minute quantities, that they are not at any time collected into body enough to be capable of flame. There is nothing to be objected as to the *bearne-ftones* fhining; tho' they are ufually white, they may poffefs no fmaller portion of fulphurs than the coloured ftones; only in thofe the fulphurs may be colourlefs, or white in themfelves.

It may be poffible alfo, that the fulphurs, in a ftone of this kind, may be difperfed in fuch fmall molecules, as not to form a body fufficient to give any colour; but when collected, in order to be driven off in the fire, they may then be fufficient in quantity to give a blue tinge to the flame.

The ifland cryftal, which is alfo a fpecies of fpar, and which greatly refembles this *bearne-ftone* in many particulars, flies to pieces alfo in the fame manner, on being heated; and when carried into the dark, this alfo gives fome fparks of light, but they are few in number, and loofely fcattered over the furface: when this ftone is burnt a little in a crucible, there is fome fmall appearance of flame, with a fmell of fulphur, and the matter in the bottom of the crucible is found fhattered to pieces; but all the pieces are regular parallelopipeds, as was the original mafs. Mem. Acad. Par. 1724.

It is to be obferved, that the *bearne ftone*, and others of the fame kind, which only fhine in the dark, and that only for a few minutes, when firft taken out of the fire, are, properly fpeaking, endued with no other luminous quality, than that of a burning coal; but their light having been generally unobferved, and requiring darknefs to fhew it, has obtained them the fpecious title of *phofphori*.

PHOSPHORUS *fæcalis*, a very fine kind of *phofphorus*, exhibiting many wonderful phænomena, and prepared from human dung mixed with alum.

Mr. Homberg, who was the inventor of it, gives the method of preparing it in the following manner: take four ounces of human dung newly made, mix it with the ſame quantity of roach alum groſsly powdered; put the mixture into a ſmall iron ladle, capable of holding about a pint; ſet it over the fire in a chimney, and it will melt together, and become as fluid as water; let it boil gently over a ſmall fire, continually ſtirring it with an iron ſpatula, till it is dry: it will then be difficult to ſtir, but it muſt be kept ſtirring about, and all the lumps it runs into muſt be broken, and what adheres to the ſides of the ladle ſtirred in and blended with the reſt: this muſt be continued till it is perfectly dry, and the ladle muſt be now and then taken from the fire, and the matter ſtirred about in it that it may not grow red-hot. When the whole is thus perfectly dried, it will ſtill be in little lumps, and when cold it muſt be rubbed to powder in a metal mortar; it muſt then be put into the ladle and ſet over the fire again, it will then become a little moiſt again, and run into clods and grumes, but it muſt be again ſtirred till dry; when cold it is to be powdered again, and a third time put into the ladle; and when perfectly dried this time, it is to be laid by in a paper in a dry place: thus is the firſt or preparatory operation finiſhed.

Take two or three drams of this powder, put it into a ſmall matraſs, capable of holding an ounce and half of water, and which has a neck ſix or ſeven inches long; put a paper ſtopper lightly into the neck of the matraſs, then take a ſmall crucible of three or four fingers breadth high, put two or three ſpoonfuls of ſand into it, then ſet the bottom of the matraſs on the ſand, and take care that no part of it touches the ſides of the crucible; fill up the reſt of the crucible with ſand, and let the whole body of the matraſs be covered with it; then ſet the crucible in one of the common little earthen furnaces, and make a charcoal fire about it; for the firſt half hour let the coals only reach up to the middle of the crucible, but afterwards lay them up to the rim of it; continue this fire about half an hour, or till the powder within the matraſs is red-hot, then pile up more charcoal above the rim of the crucible, and continue this fire an hour, after which let the whole cool. There will ariſe a large quantity of fumes during the operation, and they will often throw out the ſtopper of the matraſs; but this muſt be replaced, and the fire a little abated in that caſe: when theſe fumes ceaſe, the fire may be raiſed without hurting the proceſs, when the crucible is ſo cool that it may be taken out of the furnace without burning the hands. This is to be done, and the matraſs is to be half raiſed out of the ſand to make it bear the cold by degrees, and its mouth muſt then be ſtopped cloſely with a cork, inſtead of its paper ſtopper. If, on ſhaking the matraſs about, the matter falls into powder, it is a proof that the operation has been well performed; but if it hang together in form of a cake, 'tis a ſign that the matter was not well roaſted in the ladle before the putting it into the matraſs.

When the operation has been well performed, and the matter is in powder in the matraſs, pour out a ſmall quantity of it on a piece of paper, and immediately ſtop the matraſs again: the powder upon the paper will immediately fume and take fire, burning the paper, and any other combuſtible matter that is in the way. If there has been too much of the powder poured out of the matraſs, it muſt not be returned in again; for tho' that ſhould be done before it begins to ſmoak, yet it will certainly ſet fire to all that is in the matraſs; from this it may be eaſily ſeen alſo, that the matter cannot be emptied out of the matraſs into a phial, but muſt always be in the veſſel in which the calcination was made.

If too much alum be uſed, the powder will not take fire at all: it will be of different colours, according to the veſſel the firſt calcination was made in, and according to the degree of fire that was uſed; hence it is ſometimes black, ſometimes brown, ſometimes red, green, yellow, or white.

It takes fire equally well in the day-time and in the night, and that without the mixture of any other ſubſtance, or without the leaſt rubbing, or any other circumſtance beſide the mere expoſure to the air. In this it differs from all the other known artificial *phoſphori*; for that of urine requires a ſmall degree of heat, in order to its burning; the ſmaragdine *phoſphorus* requires a conſiderable degree; the Bononian ſtone does not ſhine except after having been expoſed to the day-light; and all the others require violent rubbing, or a ſmart blow to produce their light.

If it be deſired to keep this powder good for any time, it muſt be put in a dry place where there is not too much heat: the mouth of the matraſs muſt be kept cloſe ſtopped, and its body covered with paper; and the place where it ſtands muſt not be in too ſtrong a light, for the open day-light has been often known to weaken its power; and, in fine, wholly to ſpoil it thro' the glaſs. Mem. Acad. Par. 1711.

Fulgurating PHOSPHORUS. See FULGURATING.

PHOSPHORUS *metallorum*, a name given by ſome chemiſts to a preparation of a certain mineral ſpar, which is found in the mines of Saxony and other places, where there is copper. The ſpar to be uſed on this occaſion is, that kind which is tinged green, and from its, in ſome degree, reſembling the colour of the emerald, is called by ſome *pſeudoſmaragdus*, and by others *lapis ſmaragdi mineralis*. This is to be powdered very fine, and this powder is to be laid on a flat plate of copper, iron, or any other metal: this plate is then to be ſet over ſome lighted charcoal, and the whole placed in a dark place. The ſpar will receive its neceſſary degree of heat for ſhining long before the metal will, and, conſequently, as ſoon as it begins to ſhine, the fire is not to be made any briſker. While the plate of metal is held in this degree of heat, and does not appear at all red, the powder upon it will ſhine like a lighted coal, and will continue ſo for ſome time. If it be removed away, and ſuffered to cool, it will be fit to repeat the experiment a ſecond time with, but its light will not be ſo ſtrong as before. Phil. Tranſ. N° 244. p. 365.

PHOSPHORUS *of ſulphur*, the name given by the French academicians to a new-diſcovered ſpecies of *phoſphorus*, which readily takes fire on being expoſed to the open air.

The invention was Mr. Le Fevre's, and the proceſs is this: The ingredients are two drams of common *ſulphur*, half an ounce of ſteel filings, ten grains of colophony, and ſix drams of common water. Theſe things being all weighed and ſet apart, powder about half a dram of the *ſulphur* in a ſmall mortar, then add the colophony, and afterwards the remainder of the *ſulphur*. When this is all reduced to a fine powder, put in the filings of ſteel, and rub the whole together till it is ſo thoroughly mixed, that the ſteel does not appear; but the colour of the whole looks every where uniform and regular: then add about twenty drops of the water; and after beating the whole together add as much more, and continue to do ſo till the maſs is of the ſubſtance of a paſte, but not too moiſt. Put this paſte into a ſmall matraſs that will contain about three ounces, and pour on it more of the water till it ſwim above the ſurface of the paſte near a quarter of an inch. The matter of the paſte will then break, and appear in form of a granulated powder under the water; put the matraſs on a ſand furnace, but give it no greater heat than that the hand can bear to lie upon the matraſs. When it begins to heat, the mixture will ferment and ſwell, and become black; it is then to be ſtirred with an iron rod, and a little more water muſt be added every quarter of an hour, till the whole is uſed. The matter will then be very black and liquid; and it is to be then taken from the fire, and ſet by for the whole night. This is the firſt and moſt eſſential part of the operation, and in this great care is to be taken that the fire be not too violent; for if the *ſulphur* be burnt, the operation will be ſpoiled, and the matter would ferment ſo high as to run over at the mouth of the veſſel.

To finiſh the operation, a little water muſt be added to the matter, ſo as to ſwim over it, and the veſſel muſt be again ſet in the ſand, and a ſtronger fire given than before; this is known to be ſtrong enough when there is any humid vapour obſerved to ariſe out of the mouth of the veſſel. This fire is to be continued about two hours, that the greater part of the humidity may be evaporated; which is known by the iron rod finding ſome reſiſtance when put into the veſſel, and the matter it brings up being granulated and ſolid, or no longer moiſt; it muſt then be immediately taken from the fire, and the whole is then finiſhed. It is neceſſary to be very exact in this laſt critical minute; for a very little longer ſtanding on the fire will burn the *ſulphur*, and render all the former care of no effect. The black matter remaining in the matraſs is to be taken out, and the ſides ſcraped clean with an iron rod; any piece of this that happens to fall upon a paper takes fire in a very little time, and burns away like the other *phoſphorus*. The proceſs is a very nice one, but by obſerving all the rules here laid down, ſeveral perſons have ſucceeded in making the *phoſphorus* to perfection: the whole intent of the operation ſeems to be to join together the minute particles of ſteel and *ſulphur*; which when thus joined cannot fail to be very inflammable, and to take fire on receiving the ſmalleſt humidity from the air to make them ferment.

It cannot but be obſerved, that this *phoſphorus* is founded on Lemery's experiments of ſteel and *ſulphur*, taking fire together; but this is a greatly more nice and accurate operation, and a fine improvement on the original plan, which was only by mixing large quantities of ſteel-filings and *ſulphur* together into a paſte with water, and burying this in the earth to make it take fire of itſelf, and thus repreſent the natural phænomena of vulcanos, thunder, lightening, &c. Mem. Acad. Par. 1728.

Phoſphorus may be kindled by the effluvia of electricity. See Phil. Tranſ. N° 475. Sect. 11.

PHOSSA, in zoology, a name underſtood by ſome to expreſs the whole genus of pigeons, but more properly it is the name of one ſpecies only, the *palumbe*, *torquatus*, or *ring-dove*. See the article RING *dove*.

PHOTINX, φῶτιγξ, in antiquity, a kind of flute in uſe among the Greeks: it was the ſame with the *plagiaula* of the Romans. *Hoſm.* Lex. Univ. in voc.

PHOXINUS, in zoology, a name given by ſome to the *rutilus*, or *common roach*. *Rondelet.* de Piſc. See the article RUTILUS.

PHOXINUS *ſquammoſus*, in zoology, the name of a ſmall freſh-water fiſh, called by ſome the *bambele*, by others the *riemling*, and by ſome the *pink*. It ſeldom is found beyond the length of two or three inches; its head is large in proportion to the reſt of its body, and is blackiſh; and the roots of all its fins have ſomething of a ſaffron colour; and the joint of the gill fins has a little prominence, which in ſome is yellow, and in others reddiſh; its ſcales are ſmall and whitiſh, and the lines on its ſides reaching from the gills to the tail are brown; its belly and ſides are a little yellowiſh; it has one fin on the back, one behind the anus, a pair at the gills, and another pair on the belly; they love running waters; and when dreſſed have a bitteriſh taſte. *Geſner*, de Aquat. p. 484.

PHRÆNIAN, in the botanical writings of the antients, a name given to a kind of *anemone*, uſed in making garlands and other ornaments.

The ſcholiaſt on Theocritus obſerves from Solibius, that the Lacedæmonians called the *anemone* in general *præniòn*; and Nicander ſeems to comprehend under this title ſeveral beautiful ſpecies of the *anemone*, which he diſtinguiſhes from the *chelidonian anemones*; but Athenæus informs us, that others have made the *chelidonian* and *phrænian anemonies* the ſame. Some have ſuppoſed the *anemonies* of the antients uſed in garlands, and thoſe uſed in medicine to be different, but the generality of authors do not warrant this.

PHRATRIARCHUS, φρατριαρχος, among the Athenians, a magiſtrate that preſided over the *phratria*, or third part of a tribe. He had the ſame power over the *phratria*, that the *phylarchus* had over the tribe. *Potter*, Archæol. Græc. T. 1. p. 78. See the article PHYLARCHUS.

PHRENITIS (*Cycl.*) — The preceding ſymptoms of this diſorder are, long watchings, troubled ſleep, and very reſtleſs dreams, acute and terrible pains of the head, an entire forgetfulneſs of every thing, and a wandering of the mind, diſcovering itſelf by inconſiſtent anſwers to queſtions, a ſmall deſire of liquors, tho' the heat of the mouth plainly indicates all that can occaſion the moſt intenſe thirſt; large and ſlow reſpiration, a weak and ſlow pulſe, and ſuppreſſion of urine. All theſe ſigns predict an approaching *phrenitis*; but when it has already ſeized the patient, the blood-veſſels of the head all ſwell, and the temporal arteries have ſo ſtrong a pulſation, that they are ſeen to beat very forcibly; the eyes ſparkle and look wild and fierce; the talk is all wild and raving; and at certain times the patient has uſually violent fits of ſtruggling to get out of bed; the extremities are cold, and the urine thin, white, and pellucid.

The perſons moſt ſubject to a *phrenitis* are thoſe of a ſanguineous and plethoric habit, and much given to anger; ſuch as are addicted to a hot diet, and the uſe of ſtrong liquors; ſuch as are many hours together expoſed to the ſun in hot weather in their daily occupations; and ſuch as have been ſubject to violent head-achs, or have had habitual hæmorrhages at the noſe ſtopped upon them, or have had the blood uſually diſcharged by the hæmorrhoids thrown up into the head; and women who have had the menſes ſtopped upon them, and the blood in the ſame manner thrown up into the head. Theſe perſons are, from ſuch circumſtances and accidents, ſubject to the *phrenitis* as an idiopathic diſtemper, dependant on no other. But beſides theſe, others are alſo very ſubject to it as a ſymptom in other diſeaſes. People in acute fevers are very often thrown into it by an incompleat critical congeſtion of blood about the head; and this principally happens to ſuch as have been treated by apothecaries in an improper and injudicious manner. From the ſudden checking of ſweats many have alſo been thrown into it, and ſome from improper bleedings, and more than all theſe by a too hot regimen.

Method of cure. A clyſter is one of the firſt things to be preſcribed in this caſe; or if this cannot be given from the violence of the patient, the bowels muſt be gently relaxed by large draughts of warm emollient liquors, with a ſmall addition of nitre; after this bleeding is to be ordered, where the pulſe and condition of the patient ſhew it to be neceſſary, and gentle alexipharmics are then to be given in repeated ſmall doſes, ſuch as the mixtura ſimplex highly camphorated, and the like; and in the intermediate times the violent emotions of the blood are to be quieted by the uſe of powders of nitre, tartar of vitriol, crab's eyes, and a ſmall portion of cinnabar; theſe are to be given with cooling emulſions; a placid regimen muſt be obſerved, and the patient kept in a gentle perſpiration; and external applications are ſometimes of great ſervice, ſuch are ſpirit of wine and camphor, rubbed on the forehead and temples, and frictions, cataplaſms of various kinds, and bliſters laid to the ſoles of the feet. *Junker*'s Conſp. Med. p. 304.

Others in this caſe apply epithems to the forehead, either of the abſolutely repellent kind, ſuch as vinegar of roſes, or of lavender; theſe are moſt proper in the beginning; and if theſe do not ſucceed, the reſolvents are left afterwards to be tried; ſuch are ſpirit of wine and camphor, and ſpirit or tincture of ſaffron; bags of camphor and nitre in powder, may alſo be applied, and if theſe fail it is proper to put on leeches to the temples and behind the ears; bleeding in the jugular vein is another method; and bliſters are to be applied to the legs and arms, and ſinapiſms to the feet, compoſed of yeaſt and ſtrong vinegar, with muſtard-ſeed, nitre, and other ingredients of that kind; and, finally, when all theſe fail, an irritation of the noſtrils to promote an hæmorrhage, and bleeding in the noſe, as practiſed in Egypt, and ſome other countries, is proper. *Heiſter*'s Conſp. Med. p. 125.

Dr. Friend has recommended bleeding at the jugular veins, in a *phrenitis* coming upon a fever; but Dr. Langriſh endeavours to prove the bleeding in this caſe to be rather hurtful; and he thinks the caſes quoted by Dr. Friend to prove his opinion, either do it not, or may be turned againſt him. See Med. Eſſ. Abrid. Vol. 2. p. 457.

PHRICODES, a term uſed by the antients for a kind of fever which is attended with a coldneſs and ſhivering, not only at the beginning of the fit, but at different intervals throughout its whole continuance. The ſemitertian fever is of this kind.

The uſual ſymptoms of theſe fevers are a remarkable lowneſs of the pulſe, which is ſcarce to be felt, but recedes as it were from the finger. The belly is tumified, and a rumbling noiſe is heard in it, and the tongue is very humid, and irrigated with a ſharp acid humor, as with the ſaliva.

PHRONTIS, a word uſed by Hippocrates as the name of a peculiar diſorder of the general nature of the melancholy affections. In this caſe the patient, he ſays, feels, as it were, a thorn pricking the abdominal viſcera; he is extremely reſtleſs and uneaſy, and always avoids light and company. He dreads being touched, and becomes timorous and afraid of every thing; he is moleſted with troubleſome dreams, and imagines that he frequently ſees ſpectres and frightful objects.

PHRYCTE, a word uſed by the antient phyſicians as a name for common reſin.

PHRYGANIDES, in natural hiſtory, a name given by authors to the fly which is produced from the *phryganium*, or common cadoſworm, found in ditches, and uſed as a bait for fiſh. This has a long body, four brown wings, and a forked tail, and is found in the month of Auguſt very frequent on waters.

PHRYGANICUS, in botany, a term uſed by Dioſcorides and many other of the antient Greeks, to expreſs ſuch herbaceous plants as have hard and woody ſtalks, ſuch are the garden thyme, and ſeveral others of that kind: they alſo called theſe plants *xylodes*, ξυλωδεις, and ξυλωδεα ποα.

PHRYGIAN, (*Cycl.*) in antient muſic, the third ſpecies of the *diapaſon*. See the article DIAPASON.

PHRYGIAN *ſtone*, *phrygius lapis*, in natural hiſtory, the name of a ſtone deſcribed by the antients, and uſed in their time in dying; probably from ſome vitriolic or aluminous ſalt contained in it, which ſerved to enliven or fix the colours uſed by the dyers.

It was a light ſpungy maſs, reſembling a pumice, and the whiteſt and lighteſt were eſteemed the beſt. Pliny gives us an account of their preparing it for uſe for dying, which was by moiſtening it with urine and then heating it red-hot, and ſuffering it to cool again: this calcination was repeated three times, and the ſtone was then fit for uſe; and Dioſcorides recommends it in medicine after burning; he ſays it was drying and aſtringent.

PHTHIRION, in botany, a name uſed by ſome authors for the *pedicularis*, or *red rattle*. *Ger.* Emac. Ind. 2. See the article PEDICULARIS.

PHTHISIS (*Cycl.*)—This diſeaſe is properly an ulcerous diſpoſition of the lungs, taking its origin from a ſtaſis of blood in that viſcus, which in time degenerates into matter, and which is attended with a very remarkable waſting of the fleſh and loſs of ſtrength. A *phthiſis* in different perſons, and at different times, differs in degree; in ſome caſes it is only a tendency to ulceration in the lungs, but in others it is an actual ulceration in that part.

In the firſt of theſe caſes, where there is only a tendency to an ulceration, the lungs are only ſtuffed up with a quantity of tenacious and viſcid matter, or of a mucous fluid, with a mixture of blood. This matter, by degrees, becomes more and more hard and tough, by the diſſipation of its more fluid parts; and hence gives a ſchirrous hardneſs to that part of the lungs where it is contained, but is not eaſily changed into abſolute matter. In this caſe the patient may live many years, and often there is no ſuſpicion of his being in a *phthiſis*.

In the ſecond caſe, or an actual exulceration of the lungs, the diſeaſe cannot long remain unknown, but the hectic fever, which is its conſtant attendant, readily diſcovers it; and the waſting of fleſh, and ſpitting of matter, ſoon bring the patient to his end, if ſpeedy and efficacious remedies are not applied.

Many are very anxious about the diſtinguiſhing a true *phthiſis* from an abdominal hectic; but this is a diſtinction of very little uſe in practice, ſince both caſes require the ſame regimen: the gently reſolvent and diſcutient medicines, and balſamics, which have nothing acid in them, are the proper method in a *phthiſis*, and are equally neceſſary in this hectic. The principal differences, however, between them are theſe: The abdominal hectic always is attended with a fever, whereas the *phthiſis* is often free from a fever, or at leaſt is not attended with one of any conſequence. If, in a ſtrong inſpiration, on drawing as much breath as may be into the lungs, the

the cough is always brought on, and there is a pain and ftraitnefs in the breaft, that alfo declares the feat of the diforder to be in the lungs.

Atrophies are alfo much of the fame nature with a *phthifis*, differing only in regard to the part they affect, and to the age of the patient. An atrophy is an injury of the glands of the mefentery, pancreas, or liver, and is common to infants; whereas the *phthifis* is a like diftemperature of the lungs, and affects perfons nearer the time of their growing to man's eftate.

A true *phthifis* is, however, to be carefully diftinguifhed from that marafmus which frequently affects old perfons: this arifes from many different caufes, but never from that of a *phthifis*, or diftemperature of the lungs. The vomica pulmonum is alfo by fome confounded with a *phthifis*, but improperly; for tho' thefe diftempers are nearly allied to one another, and often degenerate into each other, yet their origin is different. The *phthifis* takes its origin from an ulcer, properly fo called; the vomica is an abfcefs, or impofthumation. The ulcer in a *phthifis* affects the humid parts of the lungs, where there is leaft blood; the vomica, on the contrary, is always feated in thofe parts where there is moft abundance of blood: fince it generally happens, that a vomica is a fhorter difeafe in its period, and carries the patient off earlier; the *phthifis* does it more flowly and gradually. When a vomica, indeed, does not carry off the patient at firft, it ufually degenerates into a true *phthifis*; and on the other hand, when the matter lodged in the lungs in a true *phthifis* is fo acrid as to corrode the veffels, then a vomica pulmonum often comes on in the courfe of that difeafe; but thefe are accidental degenerations of one difeafe into another, and tho' the firft cafe is frequent, the other is more rare.

Signs of a phthifis. This difeafe, when it begins flowly and gradually, has fcarce any figns at all by which it may be known: the utmoft fymptoms of it in this cafe, is a cough, which, tho' not violent, will not be cured. This cough, by degrees, increafes, and holds the patient always, in fpite of medicines: in fome cafes it is moderate, but in others it becomes in a little time very violent. This cough is in fome attended with a confiderable fpitting, in others with very little, and in fome perfons, both at the beginning and end of the diftemper, with no fpitting at all.

It is, however, a vulgar error to fuppofe every cough attended with fpitting to be a confumption, for very frequently the faults of the firft concoction will give origin to coughs more violent, and attended with greater fpitting than thofe in a genuine *phthifis*. Hence, for the proper diftinguifhing of a *phthifis*, many other fymptoms are neceffary: thefe are, that the patient be of an age fuited to this difeafe, in general, between fifteen and thirty-five: the cough alfo, in a true *phthifis*, is continual, and always becomes much more violent on being expofed to the cold, as alfo on drawing the breath very deeply, or taking the effluvia of any acrid fubftances: when the matter feems fetched up from very deep, and is ftreaked with blood, or is of an ill fmell, and approaching to the nature of matter; this alfo denotes the cafe to be a true *phthifis*. This difeafe is always attended alfo with a decay of ftrength, a fenfation of a ftraitnefs in the breaft, a want of appetite, or a defire for nothing but cold foods and drinks. The fleep in this cafe alfo rather tires and weakens than refrefhes the patient, and the mouth is dry, the faliva glutinous, and the temper ufually peevifh, and affected ftrongly at trifles; the body alfo becomes extremely fenfible of all changes of the weather. If thefe fymptoms happen in a cafe where there is either an hereditary difpofition to a *phthifis*, or where there has been any prior injury done to the lungs, there is no room to doubt but that the cafe is a true confumption or *phthifis*.

Thefe prior injuries of the lungs may be either from preceding difeafes, fuch as a fpitting of blood, a peripneumony, or the like; or from external contufions or wounds of the breaft; or finally, from frequently being among the vapours of corrofive medicines: and when thefe are attended with a hectic, or lofs of flefh in the whole body, and particularly in the face, there is not the leaft room to doubt but that the cafe is a dangerous *phthifis*. The fpitting of purulent matter is one of the moft certain figns of a perfect *phthifis*, but it is not an univerfal one; for there are fome cafes in which the bronchia and membraneous portions of the lungs only are affected, in which a *phthifis* may arrive at its greateft degree without any fuch fpitting. It is alfo to be obferved, that the common thick, yellowifh, or greenifh matter, which is frequently voided in large quantities in fimple coughs, is not to be confounded with the purulent matter voided in a continued *phthifis*.

The urine of people in this difeafe is ufually very like that of perfons in health, except that it retains its froth longer; this, however, is no certain fymptom of the difeafe, for it frequently happens in cafes of fimple colds, in people of phlegmatic habits.

If a vomica pulmonum comes on from a *phthifis*, the fever, which was before a flow one, affumes the appearance of an acute one; and the pain that attends the cough becomes more violent, and refpiration more difficult; finally, colliquative fweats, and diarrhœas, are very fatal fymptoms, ufually appearing towards the laft ftages.

Perfons fubject to a PHTHISIS. Thefe are principally young people of a plethoric habit, accuftomed to perfect health, and of florid conftitutions, particularly fuch as live idle lives. Thofe who labour hard, or are of a fcorbutic or phlegmatic habit, are more than all others free from this difeafe. Perfons who are fubject to hæmorrhages of any kind, or to violent pains in the head, and thofe who find their breath very fhort after a little exercife, and particularly fuch as have had at any time fpitings of blood, are moft fubject to this diftemper; as thofe, on the contrary, who are fubject to cattarrhal defluctions, to fimple coughs, or to diarrhœas, or cutaneous eruptions, or external ulcers, are ufually free from it. Women in general are much more expofed to *phthifes* than men; and that for this plain reafon: the fuppreffion of any habitual hæmorrhage, endangers the patient as to this difeafe; and women are well known to be more fubject to evacuations of blood than men; and alfo to the fuppreffions of thofe evacuations.

Old people are very feldom found to have *phthifes*, unlefs they arife from violent external injuries; and very young perfons are as feldom liable to them, unlefs from fuppreffions of large and habitual hæmorrhages by the nofe.

Caufes of a PHTHISIS. The remote caufe of this difeafe, is a plethoric habit; the proximate caufe is a congeftion of florid, rarely of ferous blood, in the breaft. The occafional, or accidental caufes, are either external injuries from blows, falls, or bruifes on the breaft, a violent cough in the autumn, at which feafon the air is peculiarly bad for all perfons inclined to a *phthifis*; the abufe of fpirituous liquors, the immoderate ufe of venery, the receiving the fumes of corrofive medicines, and finally, the improper cure of other difeafes, particularly the fuppreffing of fevers and hæmorrhages by aftringents, without any previous cautions. An hereditary difpofition is alfo frequently in fault; the cough which attends this difeafe is only an effort of nature, to break through the congeftion in the firft ftages, and in the latter, to throw up the matter occafioned by it.

Prognoftics in it. A true *phthifis*, even in its beginning, is a dangerous difeafe, and admits but of a very dubious prognoftic; but when in an advanced ftate, it is always fatal. The reafon of this is evident, becaufe there are in this cafe real ulcers in the lungs, and we well know that no ulcer can be cured till it is firft perfectly cleanfed, and that is not eafy in an internal part; and after this, the healing up of a wound in the lungs is fcarce to be expected, as thofe parts are continually difturbed by the very drawing in and voiding the breath, and greatly more fo by the cough. There have been, however, inftances of cures in the beginning of a *phthifis*, in which there have been evident proofs of a reftitution and cicatrization of the parts.

People of a dry habit are much fooner carried off by it than thofe of a moift one; as are alfo thofe of a brifk difpofition, than thofe of a more languid temper; and finally, younger perfons ufually die fooner in it, than thofe who are more advanced in years. Women, as they are more fubject to a *phthifis* than men, fo they are more eafily cured. This diftemper is often brought upon them merely from a fuppreffion of the menfes, and in that cafe it is often cured only by regularly bringing them again to their proper periods. The hectic fever in thefe cafes is what haftens the death of the patient; fo that the lefs of that fever the patient has, the longer he lives under it.

When the fpitting of true purulent matter is come on, and is attended with colliquative fweats and a diarrhœa, there is no farther hope for the patient; and in general, what is reported of the curing of confumptions, is founded on errors, and other cafes have been miftaken for it. A catarrhal cough become habitual, and attended with a voiding of a thick, pulpy, greenifh matter, is often miftaken for a confumption: as is alfo a flow fever, attended with copious fweats, and an extenuation of the body; or a recent hectic, arifing from a continued flow fever; or a merely afthmatic diforder of the breaft; or finally, a hæmoptyfis has been miftaken for a *phthifis*. In all the cafes faid to have been *phthifes*, and perfectly cured, either one of thefe has been the cafe, or the mere ftrength of nature, affifted by happy circumftances in the conftitution, not to be expected from one perfon in a thoufand, have carried the patient through it.

Method of Cure. The general method in a genuine *phthifis*, is to refpect firft the refolving, abftergiug, and difcuffing the ulcerous matter in the lungs; and after this to attempt the cleanfing and healing of the ulcers; afterwards to reftore the ftrength by analeptics, and to give the weakened parts their due tone again: and during this, the feveral fymptoms, fuch as the cough, fever, &c. are to be palliated as much as may be

To this end, in the beginning of the courfe, gentle laxatives are by all means to be given; fuch as fmall dofes of rhubarb, with manna, tamarinds, and the like: and in fubjects abounding with bad humors, jalap, fena, and, in fome cafes, even mercurius dulcis are found neceffary; but this laft medicine is only to be given with the utmoft caution, for fear of a falivation. After a few dofes of the laxatives, the refolvent, abftergent, and difcutient medicines are to be given for feveral weeks together; fuch are, decoctions of pimpernell, elecampane, florentine, iris, birth-wort, and frefh arum-root,

root, with maidenhair, horehound, hyssop, and daisy-leaves: the gum-resins are also to be given in small doses; such as ammoniacum, sagapenum, and the like; and mixtures of crabs eyes saturated with lemon juice, with vitriolated tartar dissolved in the pectoral waters, are to be given every day three or four times: a little nitre cautiously given in the intermediate times, will also be of great use in abating or taking off the fever. After this, the healing the ulcerated parts is to be attempted by the more temperate balsamics; such as boiled turpentine, mastic, olibanum, balsam of Peru and capivi, and Lucatellus's balsam: with these there always must be joined such things as will nourish and give strength; such are emulsions made rich with sweet almonds, with jellies and conserve of roses.

If the violence of the disorder is found to remit on this Method, it will be proper to give a mixture of spirit of sal armoniac, with tincture of salt of tartar, in doses of about twenty drops, three times a day: this is greatly serviceable in restoring the parts to their due tone; and if the cough still continues violent, it will be proper to give small doses of the storax-pill at night. If the disease is finally taken off by this method, it will be proper afterwards, by way of prevention, to bleed freely in the foot every spring and autumn; to recall, by all possible means, any habitual discharges of blood that had been stopped or suppressed; and particularly in men to promote a discharge by the hæmorrhoidal veins, by applying leeches to the part: the patient is not to be loaded with medicines in this case, but it will be sufficient always to keep the bowels moderately open, and to use moderate, but not violent exercise, with diets that are soft and easy of digestion. *Junck.* Consp. Med. p. 160, seq.

Mr. de Sault endeavours to prove, that a consumption of the lungs always depends on tubercles, and that an ulcer there is only an effect of these tubercles; and when the disease is in its last stadium, and incurable, it then only becomes contagious, by small worms, which it communicates to others. The cure which he proposes for the consumption, before it comes to the last stage, is to resolve the tubercles with mercury, steel, millepedes, and the aperient and antiscorbutic plants. He remarks, that the liver is generally hard in this disease; and therefore he applies a warm mercurial plaister to the right hypochondriac region, rubbing some mercurial ointment every night on the skin of that part; then continues in the use of tablets made with steel, millepedes, benzoin, coral and crabs-eyes, of each half an ounce; cinnamon, three drachms; sugar, half a pound; mix all with the mucilage of gum-tragacanth, made with orange-flower water. The dose of these tablets is two drachms, morning and evening, washing it down with a ptisan made of the roots of nettles, two ounces of the juice of water-cresses, and as much juice of cervill. Med. Eff. Edinb. He says this method, with riding, has often been successful.

Dr. Cheyne thinks that a total milk and seed diet, with frequent phlebotomies, vomits, bark in the morning and rhubarb at night, will totally cure consumptions. See his Nat. Method. of Cures, p. 264.

Morton reckons among the species of *phthisis*, those proceeding from the diarrhœa, dysentery, gonorrhœa, hæmorrhage, and dropsy, and from many other diseases; and perhaps there are many other remote causes which can produce a consumption, without varying the common immediate cause of the disease, or the method of cure. Med. Eff. Edinb V. I p. 266.

This distemper, according to some, is principally to be cured by frequent bleedings in small quantities. Med. Eff. Edinb.

PHU, in botany, a name by which some authors call the great garden valerian. *C. Bauh.* p. 164.

PHYCIS, in zoology, the name of a fish of the truttaceous kind, more usually called *callarias*, or *asellus callarias*, and *tinca marina*, or sea-tench. *Gesner*, de Pisc p. 819. See the article CALLARIAS.

PHYCIS, in ichthyology, is also a name given by Artedi, after Aristotle, Pliny, and the rest of the antients, to a fish nearly allied to the genus of the *blenni*, and called by some *trebius* and *fuca*; and according to Rondeletius, the *tinca marina* of the Italians. Salvian, however, denies that it is the *tinca marina*, and the matter is yet undecided among the writers on this subject. See TINCA *marina*.

PHYCITES, in natural history, the name given by the antients to a stone which had the impression of a sea plant of the fucus or alga kind; probably in the manner in which our black coal slate is frequently found to contain the impressions of fern and other vegetables.

PHYLACISTÆ, among the antients, officers to whose keeping the slaves in prisons and work-houses were committed. *Pitisc.* Lex. Ant. in voc.

PHYLARCHUS, φύλαρχος, among the Athenians. The *phylarchi* were magistrates who had each of them the government of a tribe committed to his charge; and their business was to take care of the public treasure belonging to each tribe, to manage all their concerns, and call them together as oft as any thing happened that required the presence of the whole body. *Potter*, Archæol Græc. l. 1. c. 13. T 1. p. 78.

PHYLATERIA, a name given by some botanical authors to the *polium*, or poly-mountain. *Ger.* Emac. Ind. 2.

PHYLLA, among the antients, wreaths, or fillets, that hung from the womens head dress, in form of flowers. *Pitisc.* Lex Antiq. in voc.

PHYLLANTHUS, in botany, the name of a genus of plants, called by Martin, in his centuries, *niruri*, as also in the hortus amstelodamensis, and malabaricus.

The characters are these: the flowers are some male and others female, produced on the same plant In the male flowers the cup is composed of one leaf, of a campanulated form, and divided into six oval and obtuse segments: these are coloured, and are the whole flower, for there are no petals. The stamina are three filaments, shorter than the cup, standing close at the base, and expanding towards the points. The antheræ are double in the female flower. The cup is the same as in the male, and there are no petals. The nectarium is a sort of rim of twelve angles, surrounding the germen of the pistil. This germen is roundish, but obtusely trigonal. The styles are three, they stand expanded, and are obtusely bifid at the extremities. The stigmata are obtuse. The fruit is a roundish capsule, marked with three furrows, and containing three cells, each composed of two valves. The seeds are single and roundish, and do not wholly fill the cells of the capsule. *Linnæi* Gen. Pl. 447. *Martin*, Cent. 1. p. 9. Hort. Mal. Vol. 10. p. 27.

PHYLLEN, in botany, a name given by some of the old authors to the *mercurialis*, or male and female French mercury. *Ger.* Emac. Ind. 2.

PHYLLEREA, *phillerey*, in botany, the name of a genus of plants, the characters of which are these: the flower consists only of one leaf, and is of a bell like shape, and divided into four segments at the edges. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower. This finally becomes a fruit of a roundish figure, containing roundish seeds

The species of *phyllerey*, enumerated by Mr. Tournefort, are these: 1. The broad-leaved smooth *phyllerey*. 2. The broad-leaved prickly *phillerey*. 3. The *phyllerey* with lightly serrated leaves. 4. The privet-leaved *phyllerey*. 5. The common narrow-leaved *phyllerey*. 6. The longer narrow-leaved *phyllerey*. 7. The narrow-leaved prickly *phyllerey*. 8. The *phyllerey* with long and deeply serrated leaves. 9. The box-leaved *phyllerey*. 10. The Spanish bay leaved prickly *phyllerey*. 11. The Spanish nerium-leaved *phyllerey*. 12. The dwarf American *phyllerey*, with thick yellow roots, and sharp-pointed leaves. And, 13. The dwarf American *phyllerey*, with a thick rose-coloured root and roundish leaves. *Tourn.* Inst. p. 596.

PHYLLITIS, *hart's tongue*. The several species of this plant see enumerated under the word LINGUA *cervina*.

It is recommended by many as an astringent, and has a place in most of our dispensatories. The common kind is esteemed the best for medicinal use; it is found in old wells, and under damp walls, sometimes in the ditches under very thick hedges. It is given, in powder or decoction, in swellings and indurations of the spleen; as also in diarrhœas, and in spitting of blood, or other hæmorrhages, externally: it is accounted a good mundificative for old ulcers. Ray, in his history of plants, tells us also, that the powder of the dried leaves does wonders in palpitations of the heart, and hysteric affections.

PHYLLITIS *marina*, *sea-hart's tongue*, in natural history, a name given by some authors to a species of sea-plant, the leaves of which, in some degree, resemble those of the common *hart's tongue*. It grows on the rocks at great depths, and is seldom seen, unless when taken up by the coral fishers. Its leaves are sometimes single, sometimes they divide into two: they are of a dusky green colour, and are about two inches in length: they have each a nerve or rib running along their middle: they are very thin and transparent, and are of a sort of cartilaginous structure; and each has several rows of small points on each side of the middle rib, which not unaptly resemble the seed-spots on the leaves of some of the capillary plants; but not on those of the *phyllitis*, or hart's tongue in particular, because they are in that plant not round but oblong, and stand only in a single row on each side the rib. When this plant is viewed by the microscope, it appears in all parts of the leaf full of little holes; and those which are so plain to the naked eye, are no other way different from the imperceptible ones, but in that they are larger. The plant has no root, and therefore takes in its nourishment by these numerous holes in its surface. *Marsigli*, Hist. Mer.

PHYLLITIS *marina Triumfetti*, in natural history, the name of a sea plant, described by count Marsigli and others, and taking its denomination from Triumfetti's judging it like the common *hart's tongue*, which grows on the sides of wells, and in other such places. It is found in great abundance on the coasts of the Mediterranean in several places at different depths, and grows to the rocks and stones. It grows to about three inches in height, and its colour is a yellowish green; it is soft and tough while in the water, but when dried it becomes very brittle, and may be rubbed to powder between the fingers. It is very elegantly branched, and its leaves are disposed with great symmetry and regularity, and are placed in a nice order for the properly receiving nourishment and conveying it all over the plant On examining these leaves with a microscope, they are found to be in reality only so many tubes, hollow all the way along, and having an aperture at the extremity,

tremity, by which they admit the sea water: as these stand above one another on the main stalks, each receives its portion of fluid, and transmits it without mixing with the rest, pure to that part of the stalk where it joins: they are all nicely jointed on to the main stalk or trunk, and that also is hollow as well as the leaves. The leaves of most of the sea plants, on being examined by the microscope, appear to be full of glandules and tubercles, which are in reality so many small pipes destined to admit the sea water; but in this plant, as that water is admitted in sufficient plenty by the extremities of the leaves, the rest of their surface is kept smooth and perfectly even. *Marsigli*, Hist. de la Mer, p. 76.

PHYLLOBOLIA, φυλλοβολία, in antiquity, a custom that prevailed among the antients to strow flowers and leaves on the tombs of the dead. The Romans adopted this custom from the Greeks, and added likewise wool. See the article BURYING.

The *phyllobolia* was also used on occasion of a victory obtained at any of the public games; when not only the victors, but likewise their parents, were strowed with flowers and leaves. *Hofm.* Lex Univ. in voc.

PHYLOBASILES, φυλοβασιλεῖς, among the Athenians, magistrates, who, with respect to particular tribes, had the same office that the *basileus* had, with respect to the commonwealth.

They were chosen out of the eupatridæ or nobility, had the care of public sacrifices, and other divine worship peculiar to their respective tribes, and kept their court in the portico called *basileion*, and sometimes in the *bucoleian*. *Potter*, Archæol. Græc.T. 1. p. 78.

PHYRAMA, in the materia medica, a name given by some of the old writers to the gum ammoniacum, particularly to that kind of it which was soft and ductile between the fingers. It is not clear that the gum ammoniacum of those times was the same thing which we now know by that name; at least it is certain, that the other kind of it, which they called *thrauma*, or *ammoniacum thraustum*, was not; for Dioscorides describes this as being of a reddish-brown colour, and very friable; and Avisenna says, that it marked a fine yellow or gold colour upon paper. These are properties by no means agreeing with our gum ammoniacum; and if justly applicable to that, must prove that it could not be the same; and the characters given by Avisenna of its bitterness, and making a yellow stain upon paper, seems to make it the *gamboge*. This, however, by no means can agree with the other virtues attributed to it.

PHYSALUS, a name given by Rondeletius to a species of sea insect, of the *scolopendra marina* kind, supposed by some to be the same with the *scolopendra marina*, or *centipes* of the Irish sea, described by Molyneux; but this does not appear to be the case, on a strict enquiry. The *physalus* of Rondeletius has no mouth, whereas the sea *centipes* of Ireland has a remarkably large one: that of Rondeletius is wider in the middle, and tapers at each end; but the Irish kind is largest at the head, and tapers from thence all the way to the tail. Rondeletius's has tubercles on the back, but the Irish one has only hairy stripes; and his is a poisonous animal, whereas that of Ireland was found in the stomach of a cod-fish, which had eaten it as food. The figure given by Rondeletius agrees also very well with the account he gives, but not with the figure of that drawn upon the spot from the Irish fish, and given in the Philosophical Transactions. On the whole, nothing is more plain than that these are two distinct species of animals, tho' of the same genus. Phil. Transf. N° 225. See the article SCOLOPENDRA.

PHYSETER, in ichthyology, the name of a genus of fishes of the *plagiure* kind, the characters of which are these: The teeth are crooked, and are placed only in the lower jaw There is one high fin or spine on the back, and a fistula or hole in the forehead. There are only two known species of this genus; these are, 1. The *physeter* with the upper jaw longer than the under one, and with a long spine on the back. The head of this fish is so large, that it is half as long as the body, and thicker than the thickest part of it. The lower part of the upper jaw runs out two foot beyond the under one, and its upper part more than five foot. The eyes are remarkably small, scarce longer than those of a haddock; the fistula or pipe, is placed a little above the center of the head; it is divided into two channels, and covered with one common operculum; the teeth are in number forty-four, and all of the shape of a reaper's sickle, roundish and a little flatted, thickest and most arched in the middle; and at the end terminating in a cone very sharp-pointed; the base is thinner than the middle of the tooth. 2. The *physeter* with a very high back-fin, with the tops of the teeth flat. This is a species of whale, described, as well as the former, by Sibbald The head is very large; the fistula, or pipe, is in the middle of the head; the fin stands so high in the middle of the back, that it has been compared to the mizzen mast of a ship. *Artedi*, Gen. Pisc See the article BALÆNA.

The name *physeter* is of Greek origin, and is derived from the verb φυσάω, to blow. It has this name from its quality of taking in a great quantity of sea water, and then blowing it out again with great force and violence.

PHYSIOLOGI, in botany, those authors whose writings tend to set that study in its clearest light, by explicating and enumerating the various dispositions of the male and female parts in the flowers of plants. *Linnæi* Fund. Bot. p. 2.

PHYSOCELE, a word used by many authors to express a *wind-rup ure.*

PHYSTA, in ichthyology, a name given by Gesner, and some others, to the fish called by the Greeks, and many of the later authors, *ballerus* and *balerus*. Artedi denies its right to any general name, reducing it to the genus of the cyprini, to which it evidently belongs, and distinguishing it from the others of that numerous genus by the specific name of the very broad and thin *cyprinus*, with forty rays in the pinna ani. See the articles BALLERUS and CYPRINUS.

PHYSTE, in the writings of the antient physicians, a word used to express a mass of meal macerated in a close vessel with wine, but not left to ferment.

PHYTALIA, a word used by the antients in two very different senses; with some expressing the latter part of the winter season, and with others a place where vines are planted, whither in standard vineyards or otherwise.

PHYTOLACA, in botany, the name of a genus of plants, the characters of which are these: The flower is of the rosaceous kind, consisting of several petals arranged in a circular order; from its center arises a pistil, which finally becomes a soft fruit or berry of an oval figure, or nearly round, and containing several seeds disposed in a circular order.

The species of *phytolaca*, enumerated by Mr. Tournefort, are these: 1. The larger fruited American *phytolaca*, called by authors the *great red cluster-fruited Virginian nightshade*. 2. The American *phytolaca*, with smaller fruit. *Tourn.* Inst. p. 299.

PHYTOLOGI, *phytologists*, authors who have written any treatise on botany, or the history or uses of vegetables. *Linnæi* Fund Bot p. 4

PIA *mater* (*Cycl.*)—According to Mr. Le Cat, the *pia mater* gives three membranes to the eye; the first lines the sclerotic coat, and is joined to it; the second is the choroid coat, and the third is the villous mammary one, proceeding from the choroid, and is commonly called *Ruysche's coat*. Med. Ess. Edinb. abrid. Vol. II p. 482.

PIABA, in ichthyology, the name of a small fresh-water fish, caught in all the fresh rivers and brooks in the Brasils, and some other parts of America.

It is of the size of the common minow; its eyes have a fine black pupil, and a yellow iris; it is covered with small scales, and has a triangular fin on its back, two under the belly, two at the gills, and one behind the anus; its tail is forked; its head is of a mixed yellow and white, and of the brightness of gold and silver; its back is of a silvery hue, with an admixture of green, and in some parts of a fine strong blue; and the sides of a silvery white and blue, without any admixture of green; and its belly of a mixed yellow and white, with only a slight cast of blue; behind each of the gills it has a fine deep blue spot, and immediately behind that another of the same colour, but of a lunated shape; and two other oblong ones of the same colour, near the origin of the tail; its tail and back-fins are yellow; its belly-fins red; it is a well-tasted fish, and much esteemed by the natives. *Willughby*'s Hist. Pisc. p. 269.

PIABUCU, in zoology, the name of an American fish eaten by the natives in many places. It is a ravenous fish, and so greedy of blood, that if a man goes into the water with a wound in any part of his body, this fish will make up to it to suck the blood. It is a small fish, seldom exceeding four inches in length, and of no great breadth; its belly is somewhat protuberant, and the whole fish is covered with bright silver-coloured scales The lines running one on each side from the gills to the tail are broad, and not shining like the rest of the body; the back is of a greenish olive-colour, and the fins are white. *Marggrave*'s Hist. of Brasil.

PIAFFEUR, in the manege, is a proud, stately horse, who, being full of mettle, or fire, restless and foreward, with a great deal of motion, and an excessive eagerness to go forwards, makes this motion the more that you endeavour to keep him in, and bends his leg up to his belly. He snorts, traverses if he can, and by his fiery action shews his restlessness; whence some, though very improperly, say, he dances. Such horses as these, or such as are bred to passage upon a straight line, are much admired in carousels and magnificent festivals. See the articles SNORT and PASSADE.

PIANISSIMO, in the Italian music, is used to signify that the part to which it is added should be played very softly, and so as that the sound may seem at a great distance, and almost lost in air. See *Corelli* Concerto VIII. in fine.

PIANO, in the Italian music, signifies soft and sweet, by way of an eccho.

PIANO PIANO, or PIU PIANO, in the Italian music, is nearly the same with *pianissimo*, or rather a degree between it and *piano*.

Piu PIANO, in the Italian music, signifies more slow, or more soft, and is much the same with *piano piano*.

PIC, an East Indian weight, containing 100 catis. See the article CATI

PICA, the *pye*, or *magpie*, in the Linnæan ſyſtem of zoology, the name of one whole order of the bird kind; the character of which is, that they have a convex beak, flatted above. The birds of this order are, the bird of paradiſe, the magpie, the crow, the cuckow, the wood-pecker, the ſitta, the creeper, the hoopoe, and the iſpida. *Linnæi* Syſtema Naturæ, p. 44.

Of this genus of birds, authors enumerate the following ſpecies: 1. The *pica varia caudata*, or common *magpie*. 2 The *pica braſilienſis*, called *toucan*. (See the article TOUCAN.) 3. The *pica glanduria*, or common jay. 4. The *garrulus argentoratenſis*, or roller. (See the article ROLLER.) 5. The *pica marina*, or ſea *pie*, a very beautiful ſpecies, being all green except the head, neck, and feet, and a ſmall part of the wings; the head is cheſnut-coloured on the top, and yellow at the ſides, and its feet brown; its claws black and very ſharp, and it has a ſmall variegation of cheſnut colour on its wings. This Mr. Ray ſuſpects, however, to be no other than the *garrulus argentoratenſis*, or roller. 6. The *pica perſica*, or Perſian *pie*, variegated with yellow; and two others mentioned by Charleton, the *pica caudata indica*, or long-tailed Indian *magpie*; and the *mimus*, or *pica garrula indica*; a bird reſembling our jay, but much ſmaller: theſe two laſt, however, are mentioned by no other author, and have never been ſeen in Europe. *Ray*'s Ornithology, p. 87, 88, 89, 90.

PICA is alſo a name by which ſome have called the *lanius*, or butcher bird. *Ray*'s Ornithology, p. 52. See the article LANIUS.

PICA *marina*, in ornithology, the name of a bird called in Engliſh the *ſea pie*, and by Bellonius and ſome others, the *hæmatopus*. It is of the ſize of the common *magpie*; its beak is three fingers breadth long, ſtrait, and of a reddiſh, or a blackiſh colour, and ending in a point, and ſeeming well-fitted for its buſineſs of rooting up the limpets from the rocks, the bodies of this fiſh being its common food; its legs are red; it has no hinder toe, and has its other toes ſo far connected by a membrane, as to ſeem almoſt of a middle nature between the web-footed and other birds; its head, neck, back, throat, and half its breaſt are black, as is alſo its rump; its tail is half black, and half white, as are alſo its wings. It is common on the weſtern ſhores of England, and on the ſhores of Wales. *Ray*'s Ornithology, p. 230.

PICA *marina* is alſo uſed by Geſner very improperly for the bird commonly known by the name of *anas arctica cluſi*. *Aldrovand.* de Avib. T. 3. p. 315. See the article DUCK.

PICA *naſi*, in medicine, a name given by Cohauſen to the immoderate taking of ſnuff. It ſeems a whimſical term, but he chuſes to treat this habit as a diſeaſe, and has written an expreſs treatiſe concerning it. The word *pica*, in general, denotes an abſurd and unnatural appetite; and the deſire of taking the powder of tobacco in this manner, is called a diſtempered appetite of the part into which it is taken, that is, the noſe. The conſequences of the taking ſnuff immoderately, are, that the ſenſe of ſmelling is either entirely deſtroyed, or at leaſt greatly impaired: for the nervous tubercles of the noſtrils being continually vellicated by this powder, are by degrees clogged up, or wholly deſtroyed, and the ſenſible membrane, which lines the noſtrils, is rendered callous, and wholly unfit for the diſcharge of its office in ſmelling. The voice is next affected by this powder; for it cauſes a ſort of aſtriction at the bottom of the noſe, which affects the palate, and conſequently the ſpeech; this gives the perſon who takes it a continual deſire of taking more and more, to rid himſelf of that ſtoppage. *Cohauſen*, de Pica Naſi.

PICACIA, a name given by the antients to that diſtempered appetite of women with child, and maidens at a certain time of life, which makes them long for things not fit for food. It is more uſually called *pica*.

PICACUROBA, in zoology, the name of a Braſilian ſpecies of pigeon, of a greyiſh colour variegated with a reddiſh brown, and with very red legs and feet. *Marggrave*'s Hiſt. of Braſil.

PICARDS *(Cycl.)* —PICARD, in our old writers, a kind of large boat, of about fifteen tons or upwards, uſed on the river Severn. Stat. 35 Hen. VIII. c. 9. 13 Eliz. c. 11.

PICICITLI, in zoology, the name of a bird of the Spaniſh Weſt Indies, deſcribed by Nieremberg. Its head and neck are black, and its whole body grey; it is a ſmall bird, and makes its appearance in Mexico after the rainy ſeaſons; it is a bird of paſſage, and it is not known where it breeds. *Ray*'s Ornithol. p 305.

PICK, among miners, is a tool with which they uſe to cut down the cliffs and rocks of ſtone to make paſſages in the earth *Houghton*'s Compl. Miner in the Explan. of the Terms.

PICK-*ax*, in the military art, a tool carried by the pioneers to dig up ground that is too hard for the ſpade; they are of great uſe for mending the ways, and in fortification.

PICKER, or *horſe*-PICKER, in the manege, an iron inſtrument five or ſix inches long, bent or crooked on one ſide, and flat and pointed on the other. It is uſed by the grooms to cleanſe the inſide of the horſes feet, and to pick out the earth, ſand, or ſmall ſtones that get into them.

PICKERELL, in ichthyology, an Engliſh name uſed by ſome authors for the *jack* or *pike*.

PICOLOS, the name of an antient Pruſſian idol, to which human ſacrifice was offered. See the article POTRIMPOS.

PICOTA, a name given by ſome authors to a diſtemper which they deſcribe as conſiſting wholly in an eruption of a number of very minute pimples upon the ſkin, all over the body; it is attended with no danger, unleſs they are ſtruck in.

PICRIS, in botany, the name given by Linnæus to a genus of plants called by Vaillant *helminthotheca*; the characters of which are theſe: The common cup is double; the outer cup is very large, and compoſed of five cordated leaves; the interior is imbricated and of an oval figure, and is not cloſe at the mouth, as the other, but open. The flower is of the compound kind, it is imbricated and uniform; and the ſmall flowers of which it is compoſed, are equal and numerous; each is compoſed of one petal, and is narrow, ligulated, and truncated at the end, where it is divided into five ſegments; the ſtamina are five capillary filaments, ſo ſhort that they are hardly ſeen; the antheræ are cylindric and tubulate; the germen of the piſtil ſtands under the flower; the ſtyle is of the length of the ſtamina, and the ſtigmata are two in number, and reflex. The cups both remain when the flowers are fallen, and ſerve as capſules for the ſeeds, which are ſingle, ventricoſe, obtuſe, and crowned with a plume of down; the receptacle is naked.

In ſome of the ſpecies of this genus, the ſeeds are crooked, and have a ſeſſile down; in others they are ſtrait, and their down is placed on a pedicle. *Linnæi* Gen. Pl. p. 377.

PICTA *toga*, among the Romans. See TOGA *picta*.

PICTAVIENSIS *colica*, the name of a kind of very terrible nervous colic, more uſually called *colica pictonum*; and by the natives in the Weſt Indies, where it rages, the *dry belly-ach*. It is ſo popular a diſeaſe in the Leeward Iſlands, that it may be very juſtly reckoned endemic among them, moſt of the people there having been at one time or other ſubject to it in all its fury. See the article COLIC.

PICUIPINIMA, in zoology, the name of a Braſilian ſpecies of pigeon, very ſmall, ſcarce exceeding the lark in ſize. Its head, neck, and wings, are all of a pale-lead colour, with a black ſemilunar mark at the extremity of each wing; but its long wing feathers, which are ſeen when the wings are expanded in flying, are of a reddiſh-brown on one ſide, and blackiſh on the other, with black ends or tips; the tail is long, and is variegated with black, white, and brown; the belly is covered with white feathers, every one of which has a brown mark of the ſhape of a half moon at the end. *Marggrave*'s Hiſt. of Braſil.

PICUS, or PICUS *martius*, in zoology, the name of a large genus of birds, of the wood-pecker kind, the characters of which are theſe: They have a ſtrait, very hard, ſtrong and ſharp beak, proper for making holes in trees; and a very long cylindrical-ſhaped tongue, terminated by a rigid and ſharp bony ſpine, ſerrated or notched at each end, proper for the ſeizing on, and tearing to pieces, of worms and other inſects; and this they can, at pleaſure, thruſt out to a great length; and ſtriking it into the clifts of trees, faſten it into inſects that lie there, and draw them out with it. Their thighs are very ſhort and ſtrong, and their toes four in number, placed two before and two behind; their tails are rigid, and bent downwards, and their feathers bare at the ends, the ſtumps aſſiſting the creature in climbing: they live only on inſects, and have only ten feathers in their tail. *Ray*'s Ornithology, p. 91.

Some underſtand the word *picus* in a larger ſenſe, making it take in the *ſitta*, *picus murarius*, *junco*, *certhia*, and all the birds that climb trees. In which caſe the characters of the genus are only, that they have very ſhort, thick, and ſtrong legs, adapted to the running up the bodies and branches of trees.

The *pici*, or wood-peckers, properly ſo called, however, are a very large and numerous family; they are, 1. The great black wood-pecker, which is all over black, except that the crown of his head is of a fine florid red. This is called the *picus niger maximus*, by authors, and is the largeſt of the whole genus: it is common in the woods of Germany, but not in England. 2. The *picus viridis*, or common green wood-pecker, well known by its beautiful colours, and its loud and diſagreeable noiſe. 3. The *picus varius major*, the great ſpotted wood-pecker. This is ſomewhat larger than the thruſh, and has a yellowiſh breaſt and beautiful redneſs near the tail. 4. The *picus varius minor*, called in Engliſh the *hickwall*. (See HICKWALL.) 5. The *picus varius Braſilienſis*, or ſpotted Braſilian wood-pecker, called the *ipecu*. (See IPECU.) 6. The *jynx*, or wry neck. (See JYNX.) 7. The *jacamaciri* of the Braſilians. 8. The *curucui*. 9. The *guira-acangatara*. 10 The *aracari*; and 11. The *guiratangemia*; and 12. The *japu* of the ſame nation; all which ſee under their ſeveral names; and beſides all theſe, Aldrovandus deſcribes another ſpecies, which he calls the *picus luteus cyanopus perſicus*, or blue-footed yellow Perſian wood-pecker. This is of the ſame ſize with the common wood-pecker; but its head and neck are thicker, and its beak longer; its feet are blue, and its general colour yellow; but with

with a broad line of a ferruginous brown down the back. *Ray's* Ornithol. p. 96. *Aldrovand.* de Avibus, l. 12. c. 35.

In the Linnæan system of zoology, the *picus* makes a distinct genus of birds, of the order of the pyes. The characters of this genus, according to this author, are, that the feet have two toes before; the tail is rigid and of the shape of a wedge; the bill is angular, and terminates in the form of a wedge; the tongue is pointed, hard, and sharp.

Of this genus are the black, green, and variegated woodpecker, and the three-toed species, described in the acta literaria sueciæ in 1740. *Linnæi* System. Natur. p 45.

PICUS *imbrifœtus*, in zoology, the name of an American bird, described by Nieremberg, and called by the natives *quatotomi*. It is of the size of the hoopoe, and is variegated with black and brown. It is of the wood-pecker kind, having a beak three finger's breadth long, with which it perforates trees. Its head is small and red, and has a fine red crest; but the feathers are black on their upper side. It has on each side of the neck a broad white line, reaching to the breast. Its legs and feet are of a bluish colour. It builds in high trees, and is principally found near the shores of the south sea. It feeds on insects. *Ray's* Ornithol. p 301.

PICUS *murarius*, in zoology, the name of a bird called in English the *wall-creeper*, and but improperly ranked among the *pici*, as wanting many of the characters of that genus. It is about the bigness of the common sparrow; its bill is black, slender, and long; its head, neck, and back grey; its breast white, and its wings partly grey and partly red; its tail is short and black; its long wing-feathers also, and the lower part of its belly, and its legs, are of the same colour; its legs are short, but its feet are not placed as in the wood pecker; but are three before, and one behind: it is very common in Italy, Germany, and some parts of France; it is a very lively and chearful bird, and as the common wood-pecker climbs trees, and feeds on the insects in their cracks; so this bird runs up old walls, and feeds on what it finds in the cracks of the stones. *Aldrovand.* de Avib. L. 12. c. 37.

PICUS *nidum suspendens*, a name by which some authors have called the *galbula*; a yellow bird of the thrush kind, very remarkable for its beauty, and for the structure and manner of hanging its nest. *Aldrovand.* de Avib. See GALBULA.

PICUS *salutiferus*, in zoology, a name under which Nieremberg has described a Mexican bird, called by the natives *henquechoitotl*.

It is of the size of the common black-bird, and has a long and black beak: its head and a great part of its neck are red: its breast and belly are grey, and it has a crest of red feathers upon its head. It is of the wood-pecker kind, and has its name from the supposed virtues of its feathers, particularly those of the crest, in curing the head-ach. *Ray's* Ornithol. p. 301.

PIEDRA *de la hyada*, in natural history, the name given by the Spaniards to a stone found in many parts of America, particularly in New Spain; and famous among the Indians for curing the colic on being applied to the navel.

It is green, and is a species of jasper, approaching to the nature of the *lapis nephriticus*, and is called by many *colicus lapis*, from its virtues.

PIERRE *d'automne*, a French name translated from the Chinese. It is the name of a medicinal stone, famous throughout the east for curing all disorders of the lungs.

Many people suppose it had its name of the *autumn-stone*, from its being only to be made at that season of the year; but it may be made equally at all times, and the origin of the name is to be farther searched into.

The Chinese chemists, like those of all other nations, delight in a sort of gibberish. A part of this is, the referring the several parts of the body to the several seasons of the year. The lungs are in this scheme referred to autumn. This appears in their writings; and thus the stone for diseases of the lungs came to be called *autumn-stone*.

It is a tedious preparation of human urine, and made as follows: they put thirty pints of the urine of a strong and healthy young man into a large iron pot, and set it over a gentle fire; and when it begins to boil, they add to it, drop by drop, about a large tea-cup full of rape-oil: it is then left on the fire till the whole is evaporated to a thick substance resembling black mud; they then take it out of the pot, and laying it on a flat iron, they dry it so that it may be powdered very fine.

This powder they moisten with fresh oil, and put the mass into a double crucible, surrounded with coals; where it stands till thoroughly dried again. They finally powder this again, and putting it into a china vessel, covered with silk cloth and a double paper, they pour on boiling water, which makes its way, drop by drop, thro' these coverings, till so much is got in, as is sufficient to reduce it to a paste. This paste is well mixed together in the vessel it is kept in, and this is put into a vessel of water, and the whole set over the fire. The matter thus becomes again dried in balneo mariæ, and is then finished. Observ. sur les Cout. de l'Asie, p. 258.

PIERIDES, among the antients, an epithet given to the muses, upon account of their having been born in that part of the country of Macedon which was called *Pieria*. *Pitisc* in voc.

PIESMA, a word used by the antients to express the remaining mass after the expression of any fluid substance from among its more solid parts. Thus the cake remaining in the bag after the expression of oils, is called by this name: but there are instances of authors calling the expressed juice, instead of the residuum, by this name. Thus Dioscorides calls the expressed juice of the bay-berries, the *piesma laurinum*; and others, the expressed juice of roses, *piesma rosarum*, paying no regard to the rose-cake left behind.

PIESTER, the name used by the antients for the press which they employed in preparing the several juices of plants, &c. hence the word *piesma*, which see.

PIESTRON, a word used by Hippocrates to express a sort of forceps, which he recommends to be used in difficult labours, to break the bones of the cranium of the fœtus, when its head is too large to suffer it to pass whole.

PIETERMAN, in zoology, the name used by some for a fish of the *cuculus* kind, approaching to the nature of the *draco marinus*, or weaver; and more usually called among authors by its Brasilian name *niqui*. *Willughby's* Hist. Pisc. p. 289. See Tab. of Fishes, N°. 39. and the article NIQUI.

PIETOSO, in the Italian music, signifies to play or sing in a soft manner, fit to move pity or compassion.

PIETRA *embosf.ata*, in natural history, a name given by the Italians to the Florentine marble, so remarkable for its delineations.

This marble is found in thin strata, and is full of cracks; in these cracks there is usually found a black mineral matter, which getting into the substance of the stone a little way on each side of the crack, forms there various delineations, or the figures of pieces of moss bushes, and the like: the paler pieces of the marble usually have these delineations; the darker coloured having the forms of trees and houses, or the ruins of old buildings. *Woodw.* Hist. Foss. V. II. p. 19.

PIEXE-*gallo*, in zoology, a name given by the Portuguese to a fish caught about the shores of the Brasils, and much resembling our *doree* or *faber piscis*; more usually known among authors by its Brasilian name, *abacatuaia*. *Willughby's* Hist. Pisc. p. 295. See ABACATUAIA.

PIEXE-*porco*, in zoology, a name by which some authors have called the *monoceros*, or unicorn fish of Clusius. The name is Portuguese, and signifies hog-fish; this little creature having a mouth like a hog. *Willughby's* Hist. Pisc. p. 150.

PIG *Guinea*. See GUINEA.

PIGAYA, in natural history, a word used by the natives of Brasil as a name for the famous *ipecacuanha*-root.

The first European who brought this root into use was an apothecary of Brasil, whose name was Michael Tristaon. The book which this author published on this subject falling into the hands of the English, is translated into our language, and stands, among a number of like accounts, among Purchas's pilgrims.

He says it is an excellent remedy against dysenteries and fluxes of all kinds. He says also, in its description, that the stalks are a quarter of a yard long, and the roots nearly as much; and that the leaves grow only four or five upon a plant.

This agrees very well with all that we have since discovered of this plant, and the method of using it at that time; we find, was not as a vomit; but they bruised the fresh root, and steeped it about twelve hours in water, at the end of which time, the patient drank the water early in the morning: it operated by stool; but after its operation, the natural purging and voiding of blood ceased. This seems the original account we have of this drug.

De Laet from this compiled his account; which is almost a literal translation of this into Latin: from his hint Piso and Margrave enquired after it more carefully upon the spot, and from them came the first accurate accounts we had of it; so that all seems, *ab origine*, deduced from Michael Tristaon's account of it.

PIGEON, in zoology. See COLUMBA.

PIGEON-*holes*, in brick-making. See BRICK.

Turbit PIGEON. See TURBIT.

PIGNOLETTI, in ichthyography, a name used by many for the *aphua cobites*, a small fish of the *gobius*, or sea-gudgeon kind, common in the Mediterranean, and brought to the markets of Rome and Venice. *Willughby's* Hist. Pisc. p. 207. See the article APHUA.

PIGUS, in zoology, the name of a species of leather-mouthed fish, very much approaching to the nature of the carp.

It is of the same shape and size with the common carp, and its eyes, fins, and fleshy palate wholly the same. From the gills to the tail there runs a crooked dotted line: its back and sides are bluish, and its belly reddish: it is covered with large scales, from the middle of every one of which there rises a fine, pellucid, and very sharp prickle.

It is a finer fish than the carp for the table, and is in season in the months of March and April. It is caught in lakes in some parts of Italy, and is mentioned by Pliny, tho' without a name.

It is a species of *cyprinus*, according to Artedi, and is distinguished by that author under the name of the *cyprinus*, called *pielo* and *pigus*. He adds, that the tail is forked, and the scales large; and that in spring and autumn there grow out of them

them white pyramidal prickles, which remain about five or fix weeks, and then fall off. The back is of a blackifh blue, and the belly white, with a faint caft of red. It never grows to more than five or fix pound weight: the flefh is well tafted. It is found in the lakes in the northern nations. *Willughby*'s Hift. Pifc. p. 247. *Rondelet* de Pifc p. 64

PIISSKER, in zoology, the name of a fifh of the *muftela* kind, ufually called the *muftela foffilis*, or *pif.is foffilis*, the foffile fifh.

This fifh is ufually found of a hand's breadth long, and as thick as one's finger; but they grow fometimes to be much longer. The back is of a grey colour, fpotted with a great number of fpots, and tranfverfe ftreaks, partly black and partly blue The belly is yellow, and is fpotted with red and white and black; the white ones are the larger, and the others look as if made with the point of a needle; and there is on each of the fides a longitudinal black and white line. There are certain flefhy excrefcences at the mouth, which in fwimming they expand; and when out of the water, they contract them

They run into caverns in the earth, in the fides of rivers, in marfhy places, and penetrate a great way, and are frequently dug up at diftances from waters; and often, when the waters of brooks and rivers fwell beyond their banks, and they are again covered by them, they make their way out of the earth into the water, and when it deferts them, are left in vaft numbers upon the ground, when they are eaten by the fwine

This feems very much of the kind of the *fifgum* fifh, and poffibly is no other than the fame fpecies; and poffibly alfo the pæcilia of Schonefeldt is the fame *Gefner* de Aquat.

PIKE, in ichthyology, a name given by us to the fifh called by authors the *lucius* and *efox*, and by the old Greek writers *oxyryn hus*. See LUCIUS and ESOX.

This fifh is the tyrant of the frefh waters, and is at once the moft voracious and the longeft lived of all fifh, according to the generality of naturalifts.

The very large *pike* are efteemed as a pompous fifh at the tables of great people; but they are coarfe, and the middling ones are in reality much the beft.

The *pike* never fwims in fhoals, as moft other fifh do, but always lies alone, and is fo bold and ravenous, that he will feize upon almoft any thing lefs than himfelf. This fifh breeds but once in a year, which is in March. It is found in almoft all frefh waters, but is very different in goodnefs, according to the nature of the places where it lives. The fineft *pike* are thofe which feed in clear rivers; thofe in ponds and meres are inferior to thefe, and the worft of all are thofe of the fen ditches. They are very plentiful in thefe laft places, where the water is foul and coloured, and their food, fuch as frogs and the like, very plentiful, but very coarfe; fo that they grow large, but are yellowifh and high-bellied, and differ greatly from thofe which live in the clearer waters.

The fifhermen have two principal ways of catching the *pike*; by the ledger, and by the walking-bait.

The ledger-bait is fixed in one certain place, and may continue while the angler is abfent: this muft be a live bait, a fifh or frog; and among fifh, the dace, roach, and gudgeon, are the beft: of frogs, the only caution is to chufe the largeft and the yelloweft that can he met with. If the bait be a fifh, the hook is to be ftuck thro' the upper lip, and the line muft be fourteen yards at leaft in length: the other end of this is to be tied to a bough of a tree, or to a ftick driven into the ground near the *pike*'s haunt, and all the line wound round a forked ftick, except about half a yard. The bait will by this means keep playing fo much under water, and the *pike* will foon lay hold of it.

If the bait be a frog then the arming wire of the hook fhould be put in at the mouth, and out at the fide; and with a needle and fome ftrong filk the hinder leg of one fide is to be faftened by one ftitch to the wire-arming of the hook. The *pike* will foon feize this, and muft have line enough to give him leave to get to his haunt and poach the bait.

The trolling for *pike* is a pleafant method alfo of taking them: in this a dead bait ferves, and none is fo proper as a gudgeon This is to be pulled about in the water till the *pike* feizes it, and then it is to have line enough, and time to fwallow it: the hook is fmall for this fport, and has a fmooth piece of lead fixed at its end to fink the bait; and the line is very long, and runs through a ring at the end of the rod, which muft not be too flender at top.

The art of feeding *pike*, fo as to make them very fat, is the giving them eels, and without this it is not to be done under a very long time; otherwife perch, while fmall, and their prickly, tender fins, are the beft food for them. Bream put into a *pike*-pond are a very proper food: they will breed freely, and their young ones make excellent food for the *pike*, who will take care that they fhall not increafe over much The numerous fhoals of roaches and ruds, which are continually changing place, and often in floods get into the *pike*'s quarters, are food for them for a long time.

Pike, when ufed to be fed hy hand, will come up to the very fhore, and take the food that is given them out of the fingers of the feeder. It is wonderful to fee with what courage they will do this, after a while practifing; and it is a very diverting fight when there are feveral of them nearly of the fame fize, to fee what ftriving and fighting there will be for the beft bits, when they are thrown in. The moft convenient place is near the mouth of the pond, and where there is about half a yard depth of water; for, by that means, the offal of the feedings will all lie in one place, and the deep water will ferve for a place to retire into and reft in, and will be always clean and in order.

Carp will be fed in the fame manner as *pike*; and 'tho' by nature a fifh as remarkably fhy and timorous as the *pike* is bold and fearlefs, yet by cuftom they will come up to take their food out of the perfon's hand; and will, like the *pike*, quarrel among one another for the niceft bits. See the article FEEDING *of fifh*.

Half PIKE, in the military art, is the weapon carried by an officer of foot. It differs from a *pike*; becaufe it is but eight or nine foot long, and the fpear is fmaller and narrower.

PIKE, is alfo the name of an Ægyptian meafure, of which there are two kinds, the large and the fmall.

The larger *pike*, called alfo the *pike* of Conftantinople, is $27\frac{930}{1000}$ Englifh inches. They meafure all foreign goods with this, excepting only fuch as are made of flax and cotton: for thefe they ufe the fmall *pike*, called *pike belledi*, or the *pike* of the country; becaufe they meafure with it all the manufactures of the country. This *pike* confifts of about $25\frac{176}{1000}$ Englifh inches. *Pocock*'s Ægypt, p 175.

PILA (*Cycl.*)—PILA *marina*, the *fea-ball*, in natural hiftory, the name of a fubftance very common on the fhores of the Mediterranean, and in fome other places. It is ufually found in form of a ball, about the fize of the balls of horfe-dung, and compofed of a multitude of fibrillæ, irregularly complicated.

Its origin has been very varioufly gueffed at by different authors. John Bauhine fays, that it confifts of fmall hairy fibres and ftraws, fuch as are found about the fea-plant called *alga vitriariorum*; but he does not pretend to afcertain what plant it owes its origin to. Imperatus judged it to confift of the exuviæ both of vegetable and animal bodies. Mercatus doubts whether it be a congeries of the fibrillæ of plants, wound up into a ball by the motion of the fea-water; or whether it be not the workmanfhip of fome fort of beetle living about the fea-fhore, and analogous to our common dung-beetles ball, which it elaborates from dung for the reception of its progeny. Schreckius will have it compofed of the filaments of fome plant of the reed kind: and Welchius fuppofes it compofed of the pappofe part of the flowers of the reed. Maurice Hoffman thinks it the excrement of the hippopotamus: and others think it that of the phoca, or fea-calf.

But Klein, who had thoroughly examined as well the bodies themfelves, as what authors had conjectured concerning them, is of opinion, that they are wholly owing to, and entirely compofed of, the capillaments which the leaves growing to the woody ftalk of the *alga vitriariorum* have, when they wither and decay. Thefe leaves, in their natural ftate, are about the thicknefs of a wheat ftraw, and they are placed fo thick about the tops and extremities of the ftalks, that they enfold, embrace, and lie over one another; and from the middle of thefe clufters of leaves, and, indeed, from the woody fubftance of the plant itfelf, there arife feveral other very long, flat, fmooth, and brittle leaves: thefe are ufually four from each tuft of the other leaves, and they have ever a common vagina, which is membranaceous and very thin. This is the ftyle of the plant, and the *pila marina* feems a clufter of the fibres of the leaves of this plant, which cover the whole ftalk divided into their conftituent fibres; and by the motion of the waves, firft broken and worn into fhort fhreds, and afterwards wound up together into a roundifh or longifh ball. *Klein*, de Tubul. Marin. p. 22.

PILARIS, or PILARIS *turdus*, in zoology, the name hy which authors in general call the field-fare. See the article FIELDFARE.

PILATIO, a word ufed by the antients to exprefs a minute fiffure in the cranium, when not larger than a fingle hair of the head.

PILATRO, or PILATRO *di Levante*, a falt ufed in the glafs trade in fome particular cafes. It is extracted from the froth of the fea, coagulated by heat in the hot countries. *Merret*'s Notes on Neri. p. 349.

PILCHARDUS, the common *pilchard*, in zoology, a fifh much approaching to the nature of the common herring, but fmaller and differing in feveral other particulars.

The diftinguifhing characters of it are thefe: it never exceeds fix or feven inches in length: its body is thicker in proportion than that of the herring, and its belly lefs fharp: its fcales are very large, round, and very thin: its back is of a bluifh green, and its belly white; and near the upper angle of the gills, it has a black fpot on each fide; fometimes alfo there are four or five other fmaller in a ftrait line behind thefe: the head is flatted, and the mouth large; but it has no teeth, neither in the jaws nor palate

It is generally found fwimming in vaft fhoals, and is caught on many parts of the Englifh fhores. Its flefh is better tafted than that of the herring.

PILE (*Cycl.*)—PILE *worms*, are a kind of *worms* found in the *piles* of the sea dikes in Holland. These *worms* are of various sizes, some of the young ones are not above an inch or two in length; but others have been found of thirteen or fourteen inches long.

The heads of these creatures were covered with two hard shells, or hemicrania; which together form a figure resembling an augur; and with which they bore the wood. The best remedy against them is, to perforate the *pile* with many small holes, about an inch asunder; then it must be done over with a varnish in the hottest sun; and while the varnish is hot, brick dust must be strewed over it; and this being several times repeated, the *pile* will be covered with a strong crust, impenetrable to all insects. See a farther account of these creatures in Phil. Transf. N° 455. Sect. 5.

PILES, the popular name for the *hæmorrhoides*. See the article HÆMORRHOIDES, *Cycl.* and *Suppl.*

PILEÆ, a name given by some authors to a genus of *echinodermata*. See the article CONULUS.

PILENTUM, among the Romans, an easy kind of chariot, used by the Roman ladies at games and religious processions. *Pitisc.* in voc.

PILEUS *presbyteri*, in botany, a name given by some writers to the *euonymus* or *fusanus*, a shrub which grows in our hedges, and bears a square fruit somewhat resembling the cap worn by some orders of priests.

PILHANNAW, a name given by the Indians to a bird found in the forests on the back of some our American plantations.

It is a bird of prey very large and bold; it is described by Josselin as four times as big as our goshawk, and having a remarkably large head. All the birds are terrified at its approach; but it principally feeds on quadrupeds, as the young fawns and the like.

PILIMICTIO, a word used by several authors to express a discharge of small and long filaments, which resemble hairs among the urine.

PILL (*Cycl.*)—*Aromatic* PILLS, *pilulæ aromaticæ*, a form of medicine in the New London Dispensatory, intended to stand in the place of the *pilulæ diambræ* of the former, and the *pilulæ alephanginæ*, or *aloephanginæ* of that, and some other Dispensatories.

The composition is this: Take socotrine aloes, an ounce and half; gum guaiacum, an ounce; the aromatic species and balsam of Peru, of each half an ounce; let the aloes and gum guaiacum be powdered separately, and afterwards mixed with the rest, and formed into a mass with syrup of orange-peel. *Pemberton's* Lond. Disp. p. 326.

PILLS *of colocynth with aloes*, *pilulæ e colocynthide cum aloe*, a name given in the New London Pharmacopœia, to the purging-*pill*, commonly known by the name of *pilulæ cocciæ minores*.

As this is originally a prescription of Galen's, and the manner of proportioning the ingredients has been altered for the worse, since his time, by enlarging the quantity of that nauseous ingredient the *colocynth*; the college have reduced it to its former proportions, and ordered it to be made in this manner: Take socotrine aloes and scammony, of each two ounces; pith of coloquintida, one ounce; oil of cloves, two drams; let the dry species be reduced to powder separately, the oil mixed among them, and the whole formed into a mass, with syrup of buckthorn. *Pemberton's* Lond. Disp. p. 327.

PILULÆ *e colocynthide simpliciores*, a name given in the late London Pharmacopœia, to the purging-*pill* commonly known by the name of *pil. ex du bus*. It is made of equal parts of colocynth and scammony, with a considerable proportion of oil of cloves; and is beat up to a consistence with syrup of buckthorn. *Pemberton's* Lond Disp p. 327.

Mercurial PILLS, *pilulæ mercuriales*, a form of medicine prescribed in the late London Pharmacopœia, and containing crude mercury mixed for internal use.

The composition is to be made as follows: Take of pure quicksilver, five drams; of Strasburg turpentine, two drams; of the cathartic extract, four scruples; rhubarb in powder, one dram; grind the quicksilver with the turpentine till it makes one uniform mass, and then add the other ingredients, and beat up the whole into *pills*. If the turpentine be too hard, it must he softened with a little oil of olives. *Pemberton's* Lond. Disp. p. 329.

Soap PILLS, *pilulæ saponaceæ*, a form of medicine prescribed in the late London Dispensatory, and ordered to be made in the following manner: Take almond *soap*, four ounces; strained opium, half an ounce; essence of lemons, a dram; soften the opium a little with wine, and beat that and the *soap* with the essence, till it be reduced to the form of a *pill*.

This is intended to stand in the place of the *pill*, commonly called *Mathew's pill*, and is very happily corrected in regard to the taste of the *soap*, by the addition of the essence of lemons. *Pemberton's* Lond. Disp. p. 231.

Ward's PILL. See WARD'S *pill*.

PILLAR (*Cycl.*)—It seems not impossible for stone to be cast into the shape of *pillars*. We find mention made in the Philosophical Transactions, of two *pillars* of stone, at Fontevraud, in France, each about 60 feet high, all of one solid piece, which are said to have been run. N° 481. p. 328. in Not.

Pillars of stone were antiently erected as sepulchral monuments, near the highways; and also in memory of some victory. We find traces of this custom in Cornwall and Wales, where these *pillars* are often found, and called *meinigwir*, a stone for play, perhaps in memory of funeral games; and sometimes *llech*, that is, *tabula saxea*. Phil. Transf. N° 458. p. 471.

PILLVENKEGEN, in zoology, the name of a bird approaching to the snipe kind, described by Aldrovand, and supposed by some to be the bird we call the *knot*. See KNOT.

PILLOW *of a plough*, a term used by the farmers to express that part of a *plough* which serves to raise or sink the beam, and with it the share, as the land is to be *ploughed* shallower or deeper.

This *pillow* is a cross piece of wood, reaching from one of the crowstaves or uprights, to the other; and as they are bored with two rows of holes, this *pillow* can be sliped up or down to any height, and kept there by pegs or cords in the holes. *Tull's* Husbandry. See PLOUGH.

PILLOW, in a ship, is that piece of timber whereon the bowsprit rests at its coming out of the hull aloft, close by the stern.

PILOSE *leaf*, among botanists. See the article LEAF.

PILOSELLA, the common *mouse-ear*, is esteemed a great medicine by many, as abstergent and astringent. It is prescribed in dysenteries, and all other hæmorrhages, and particularly in bleedings at the nose. Some have given it a great character also in the cure of ruptures; and its juice is said to be a very great remedy in the milliary herpes, rubbed on the part.

PILOTING, *in navigation*. See the articles NAVIGATION and PILOT, *Cycl.*

PILULARIA, *pepper-grass*, the name of a very remarkable little plant, of which Mr. Bernard de Jussieu has given a very accurate account in the Memoirs of the Academy of Sciences of Paris.

It is a low and creeping plant, always being procumbent upon the earth; its roots are long, slender, white filaments, which pierce perpendicularly down, and have at their extremities a few short fibres. Every one of these roots is fixed to the base of one of the leaves that stand on the branches. The branches are divided and spread about, and are all so regular in size, and so oddly interwoven among one another, that it is not easy to say which of them is the main stalk, which the ramifications; but the several radicles which usually go down very deep, keep the whole lengths of the branches close down to the ground. The branches are round, green, and knotty; and their ramifications are placed alternately, and are terminated by a protuberance or soft button, or a small leaf rolled up in a spiral form.

The leaves stand also alternately on the branches, and are strait, narrow, and somewhat cylindric in shape, and pointed at the end; they resemble, in some sort, the young shoots of rushes, and are seldom more than four inches long; nor are the stalks usually more than six.

The flowers of this plant stand in the alæ of the branches, and four flowers, each enveloped by its own peculiar membrane, which is very fine and delicate, are always contained in one common covering; which resembles a sphere set all over with prickles or hairs. This globule increases at length to the size of a pepper-corn; and when mature, it opens into four quarters, each of which has its peculiar pedicle, by which it adheres to the branch.

The membrane which envelopes each particular flower, or as it may be called, each quarter of the globule, is very fine and delicate; and each has three faces; one convex, and the other two in form of semi-circles. The inferior angles of these three faces terminate in one common point; and the semi-circular faces open a little at the opposite end, to disclose the flower. See Tab. of Mosses, N° 21.

Every quarter of the globule is hollow, and has the shape of a quarter of a regular hollow sphere, and contains its perfect flower, which is of the hermaphrodite kind, containing stamina and pistils, arranged on, and fixed to a common placenta. This placenta is a membranaceous band, fastened to the inner spherical part of the membrane, which incloses the flower; it occupies only about half the cavity, and is so formed as to represent, in some measure, two thirds of a crescent; from which one of the points had been cut off. This placenta is, in a manner, surrounded with pistils, having four series of them on each side; some of which stand opposite to others, and some are erect, while others lie horizontally. The pistils fill up two thirds of the cavity of the flower, and the rest is occupied by the stamina; which are so many little horns all growing from a little head, which stands in the angle made by the sides of the placenta. The stamina diverging from this point, form a sort of pyramidal cluster. The number of the pistil is various in different flowers; some having twelve, others twenty; they are each of them of an oval figure, and are enveloped each in a fine thin membrane, which is folded and wrinkled. They have no style, but have only a downy prominence on their upper extremity, which may be properly called the stigma.

These pistils are so many embryo seeds; the stamina are usually more than thirty in number, and are so small as not to be easily discoverable to the naked eye; and 'tis from this minute-

minutenefs of the feveral parts of the flower of this plant, that it has been generally fuppofed, by botanifts, to have no flower at all; the globule at the root of the leaves having been ufually efteemed merely a capfule for the feeds.

The pedicles, on which thefe globules ftand, are not more than a twelfth of an inch long; and it has ufually, at its bafe, two or three fmall leaves of the fame fhape with the other leaves of the plant. The globules ufually ftand fingly at the bottom of each leaf. The ftamina of the flowers, examined by the microfcope, appear compofed of a fine tender membrane, inclofing a number of fmall round bodies; and the whole affuming a conic form: thefe put into a drop of water before the microfcope, received the humidity into them, and fwelled into the figure of an oblong pearl, and foon after burfting open tranfverfely, they difcharged their grains of fine powder with an elaftic force: thefe grains, which are the globules of the farina, are regularly round and rough on the furface; they fwell on lying in the water, but never burft. The piftils, on being put into water, loofe their folded and wrinkled figure, and fwell into a fort of bladder: thefe piftils finally become each a perfect feed, which is rounded at the bottom, and terminates in a point at the top, and of a fomewhat yellowifh white colour.

The feeds of the *pilularia* fend up fingle leaves of the fhape of thofe which afterwards appear on the whole plant; and the herb is therefore of the order of the *monocotyledones*; and, according to the opinion of Mr. Juffieu, approaches more to the nature of the *ferns* than to any other clafs of plants, tho' fo widely different from them in the manner of growth: he is for allotting it a place, however, next the *ferns*, and that for the following reafons:

1. Becaufe the *pilularia* imitates the difpofition and arrangement of the branches of many of the *ferns*, tho' in fo extremely different a form, creeping over the ground with its horizontal roots, in the manner of the common female *fern*, and like it, having its leaves and branches placed in an alternate manner.

2. Becaufe the young leaves of the *pilularia* are enveloped like thofe of the *ferns*, with a fort of down, and are rolled up in the fame manner, in a fpiral form; from which they gradually expand.

3. Becaufe the tafte is the fame with that of the *ferns*, vifcous, with a gentle aftriction.

4. Becaufe the fmell of the leaves, when bruifed, is wholly the fame with that of *fern*; and, finally, becaufe the fummits of the ftamina, when nicely examined, appear to have a great analogy with fome parts of the fructifications of the *ferns*. Memoirs Acad. Scien. 1739.

PIMIENTA, in botany, the Jamaica *pepper-tree*; the characters of which are thefe: Its trunk is as thick as one's thigh, rifing ftreight about 30 feet high, covered with an extremely polifhed or fmooth fkin, of a grey colour, and branched out on every hand; having the ends of its twigs fet with leaves of feveral fizes; the largeft being four or five inches long, two or three broad in the middle, where broadeft; whence it decreafes to both extremes, ending in a point, fmooth, thin, fhining, without any incifures, of a deep green colour, and ftanding on inch-long foot ftalks; when bruifed very odoriferous, and in all things like the leaves of a bay-tree. The ends of the twigs are branched into bunches of flowers, each footftalk fuftaining a flower made up of four herbaceous pale-green petala, bowed back, or reflected downwards; within which are many ftamina of the fame colour. Thefe are followed by a bunch of crowned or umbilicated berries, (the crown being made up of four fmall foliola or leaves) which are bigger, when ripe, than juniper-berries, at firft when fmall, greenifh; but when ripe they are black, fmooth, and fhining, containing in a moift, green, aromatic, and biting pulp, two large *acini*, or feeds, feparated by a membrane lying between them, each whereof is a hemifphere, and both joined make a globe or fpherical *acinus*; whence Clufius makes it one feed, divifible into two parts.

It grows on the hilly parts of Jamaica, and is much cultivated there; becaufe of the great profit from the cured fruit fent in great quantities yearly into Europe.

It flowers in June, July, and Auguft, fooner or later, according to its fituation and the different feafons for rain; and after it flowers, the fruit foon ripens.

There is little difficulty in curing and preferving this fruit for ufe, which is done thus: the Negroes climb the trees and pull off the twigs with the unripe green fruit, and afterwards carefully feparate the fruit from the twigs, leaves, and ripe berries; which done, they expofe them to the fun from its rifing to fetting, for many days, fpreading them thin on cloaths, turning them now and then, and carefully avoiding the dews. By this management they become a little rugous or wrinkled, dry, and from a green change to a brown colour, and then they are fit for the market.

The ripe berries are very carefully feparated from thofe to be cured; becaufe their wet and plenteous pulp renders them unfit for cure.

It is accounted the beft and moft temperate, mild and innocent, of common fpices, and fit to come into greater ufe, and to gain more ground than it hath yet done. It furpaffes moft of the Eaft Indian aromatics in promoting the digeftion of meat, attenuating, tough humors, moderately heating, ftrengthening the ftomach, expelling wind, and doing thofe friendly offices to the bowels we generally expect from fpices. Clufius takes it to be the *garyophyllon* of Pliny; and by others it is fuppofed to be the *amomum* of the antients; but 'tis not likely that it was known to the antients, not being known to grow in the Eaft, but Weft Indies; whence it was brought to England, and fent to Clufius, who firft defcribed and figured it, giving it the name of *amomum quorundam*, or *caryophyllon Plinii*. Phil. Tranf N° 192. See the article PIPER.

PIMP-*tenure*, a kind of *tenure* mentioned in our old writers.— Willielmus Hoppefhort, *Tenet dimidiam Virgatam terræ, per fervitium cuftodiendi fex Damifellos fcil. Meretrices, ad ufum Domini Regis.* 12 Ed. I. *Blount's* Ten. 39.

PIMPERNELL, *pimpinella*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one petal, which is of a rotated form, and is deeply divided into four fegments, and contains a vaft number of ftamina, or a fimbriated ftyle. The cup finally becomes a fruit ufually of a quadrangular figure, and pointed at each end: this is fometimes divided into two cells, fometimes it confifts only of one; and it contains numerous feeds, ufually of a longifh figure.

The fpecies of *pimpinella*, enumerated by Mr. Tournefort, are thefe: 1. The common greater *pimpinella*, called *Burnet faxifrage*; and by moft authors *pimpinella fanguiforba major*. 2. The great rigid very tall *pimpinella*, with auriculated leaves. 3. The great Spanifh *pimpinella*, with a pale-red fpike. 4. The great Spanifh *pimpinella*, with cluftered flowers. 5. The American *pimpinella*, with long red fpikes. 6. The greateft American *pimpinella*, with white fpiked flowers. 7. The fweet agrimony-leaved *pimpinella*. 8. The fmaller hairy *pimpinella*. 9. The fmall fmooth *pimpinella*. 10. The fmall fcentlefs *pimpinella*. 11. The fmaller *pimpinella*, with large thick feeds. And 12. The prickly ever green *pimpinella*, called by fome authors *poterium*, and by others *colchicum*. *Tourn.* Inft. p. 157.

The feeds of this plant are warm, carminative, and difcutient: they are given with fuccefs in colics and flatulencies, and in fuppreffions of urine. The leaves and roots alfo poffefs the fame virtues; and when the diuretic property only is expected from it, the root alone frefh taken up, cut fmall, and boiled in water, is the beft. The decoction is to be drank in large draughts, and often repeated.

Red PIMPERNELL, *anagallis*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf, and is rotated and divided into feveral fegments. The piftil arifes from the cup, and is fixed in the manner of a nail, to the lower part of the flower: this afterwards becomes a fhelly fruit, of nearly a globular figure; which, when ripe, divides tranfverfely into two parts, and difcovers a number of angular feeds affixed to a placenta.

The fpecies of *anagallis*, enumerated by authors, are thefe: 1. The common red flowered *anagallis*. 2. The larger leaved red-flowered *anagallis*, with leaves growing four at a joint. 3. The common blue-flowered *anagallis*. 4. The blue-flowered *anagallis*, with two or three leaves at every joint. 5. The ferrugineous flowered *anagallis*. 6. The dufky purple-flowered *anagallis*. 7. The pale red-flowered *anagallis*. 8. The white-flowered *anagallis*. 9. The broad-leaved Spanifh *anagallis*, with large blue flowers. 10. The round-leaved Portugal *anagallis*. 11. The broad-leaved Portugal *anagallis*, with a fmall flower. 12. The great toad-flax-leaved *anagallis* of Portugal. 13. The narrower-leaved *anagallis* of Portugal. 14. The fmalleft *anagallis*. 15. The fmall French, fea, round-leaved *anagallis*.

Authors name, befide thefe, feveral other plants *anagallis aquatica*, the *brooklime*, &c. but thefe are properly either of the genus of the *veronica*, or that of the *famolus*. *Tourn.* Inft. p. 142. See the article SAMOLUS, &c.

PIMPILIM, in botany, a name by which fome authors have called the plant which produces the long pepper, ufed in medicine. *Pifo*, Mant. 182.

PIMPINELLA. See PIMPERNELL, fupra.

PIMPLE, in medicine, a fmall puftule arifing on the face.

By mixing equal quantities of the juice of houfe-leek, *fedum minus*, paffed through paper, and of fpirit of wine rectified by itfelf, a white coagulum of a very volatile nature is formed, which Dr. Burghart commends for curing *pimples* of the face; and fays, that the thin liquor feparated from it, with fugar-candy, is an excellent remedy for thick vifcid phlegm in the breaft. Satyr. Silefiac. Spec. 4. Ob. 2.

PINACOTHECA, among the antients, a place where pictures, ftatues, and other curiofities were kept *Pitifc* in voc.

PINACIA, πινακια among the Athenians, tablets of brafs, whereon the names of all the perfons in each tribe duly qualified, and willing to be judges or fenators of the Areopagus, being feverally written, they were caft into a veffel provided on purpofe; and into another veffel were caft the fame number of beans, an hundred of which were white, and all the reft black. Then the names of the candidates and the beans were drawn, one by one; and thofe whofe names were drawn out together with the white beans, were received into the fenate. See the article PROBULEUMA.

In

In Solon's time there were only four tribes, each of which elected an hundred senators; so that the Areopagus consisted of four hundred members: but the number of tribes being afterwards encreased, the number of senators was consequently augmented by some hundreds; b t the manner of election remained the same. *Pott.* Archæol. Græc. T. 1. p. 97. See the article AREOPAGUS, *Cycl.*

PINARII, among the Romans, an order of under-priests belonging to Hercules, who offered sacrifices to that god morning and evening. They were only servants to the *potitii* *Danet.* in voc. See the article POTITII.

PINCHING *(Cycl.)*—PINCHING, in horsemanship, a term used to express a method of trying a horse's mettle, or vigour, and of shewing it to a purchaser when the creature is on sale. The whole method is, when the rider is on his back, he keeps him standing still, and keeping him fast with the bridle-hand, he applies the spurs to the hair of the sides. If the horse is impatient under this, and draws himself up, and wants to go forward, it is a sign of vigour and mettle. But the purchaser ought to try the thing himself on the horse's back; for the jockies have the art of making the dullest horse seem to have mettle in these trials. The purchaser must also distinguish between the restlesness of the horse under this treatment that arises from vigour, and that which arises from the horse's being ticklish, and which goes off immediately. See the article METTLE.

PINDAIBA, in botany, the name used by some authors for the tree which produces the cubebs of the shops. *Piso*, p. 144.

PINE-*tree*, *pinus*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the amentaceous kind, being composed of a great number of stamina, but it is barren: the embryo fruit appear in other parts of the tree, and finally become a sort of cone; between the several scales of which, eachhaving two hollows, there are found two seeds contained in a stony husk, which is frequently alated. To this it is to be added, that the leaves grow more than one out of the same theca.

The species of *pine*, enumerated by Mr. Tournefort, are these: 1. The common manured *pine*. 2. The common wild mountain *pine*. 3. The tender fruited wild *pine*, called *cambro*. 4. The mountain *pine*, called by authors *mugho*. 5. The wild sea-*pine*, with the cones growing firmly to the branches. 6. The Idæan sea-*pine*. 7. The small sea-*pinaster*. 8. The dwarf *pine*, with pale or greenish juli. 9. The dwarf *pine*, with purple juli. And, 10. The *pine* with erect cones, called by some the Austrian *pinaster*. *Tourn.* Inst. p. 585.

The leaves and tender tops of *pine* and fir are used for diet-drinks, and allowed to be antiscorbutic and diuretic.

The resinous exsudations of *pines* and firs are an important branch in the materia medica, and not only useful in the prescriptions of physicians, but have also been thought otherwise conducive to health. Pliny tells us, that wines, in the time of the old Romans, were medicated with pitch and resin. And Jonstonus, in his dendrographia, observes, that it is wholesome to walk in groves of *pine*-trees, which impregnate the air with balsamic particles. It is known that all turpentines and resins are good for the lungs, against gravel also, and obstructions: and it is said, that the medicinal properties of those drugs are found in tar-water, which operate without heating the blood or disordering the stomach. See the article TAR-*water*.

Pitch, tar, rosin, and turpentine, are all made from these trees by a very familiar process. In the spring time, when the sap is most free in running, they pare off the bark of the *pine*-tree, to make the sap run down into a hole which they cut at the bottom to receive it; in the way, as it runs down, it leaves a white matter like cream, but a little thicker: this is very different from all the kinds of resin and turpentine in use, and it is generally sold to be used in the making of flambeaux, instead of white bees-wax. The matter that is received in the hole at the bottom, is taken up with ladles, and put into a large basket; a great part of this immediately runs thro', and this is the common turpentine. This is received into stone or earthen pots, and is ready for sale. The thicker matter, which remains in the basket, they put into a common alembic, and adding a large quantity of water, they distil this so long as any oil is seen swimming upon the water; this oil they separate from the surface in large quantities, and this is the common oil or spirit of turpentine: the remaining matter at the bottom of the still, is common yellow resin. When they have thus obtained all that they can from the sap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with these billets; and setting them on fire, there runs from them while they are burning, a black thick matter: this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil: if this hole be made too large, it sets the whole quantity of the tar on fire; but if small enough, it runs quietly out.

The tar being thus made, is put up in barrels; and if it be to be made into pitch, they put it into large boiling vessels, without adding any thing to it: it is then suffered to boil a while, and being then let out, is found, when cold, to be what we call pitch. Phil. Trans. N°. 243. p. 291.

Silver PINE, in botany. A branch of this tree being brought from the Cape of Good Hope, by Mr. Goddard, and presented to the royal society, Dr. Sloane gave the following account of it: The twig of this tree had a great many leaves set round it, very close to one another, so as to hide the twig itself there where they grow; each of the largest being about four inches long, and three quarters of an inch broad in the middle where broadest, from whence they decrease towards both extremes, ending in a point; being like those of the osier willow, only broader, and all covered over with the thickest, finest, and longest, white silken hair, or down, that ever any plant the doctor remembers to have seen. The cones are of the bigness of those of the cedars of Lebanon, and of the same shape; The cuticula, or small skin of each scale, being covered over with a white short down or wool, shining also like silk. Between the scales is lodged the seed, whi h is almost as large as the *pine* nut, near the same shape, of a dark brown colour, and having a rising eminent line or belly running through the middle of it from end to end. This seed lies in a thin, reddish brown membrane, which has on its top four feathers, like those belonging to the seed of the clematitis; which being between the scales, and rising above them, adds a very great beauty to the cone, and may likewise serve for wings, by means of the wind, to loosen or carry the seed to distant places, thereby propagating itself. Dr. Plucknet calls it *leucodendr os.* Phil. Trans. N°. 198.

Spunge-leaved PINE, in botany. A branch of this tree being brought from the Cape of Good Hope by Mr. Goddard, and presented to the royal society, Dr. Sloane gave the following description of it: The bark was of a brown colour and smooth; its wood whitish and hard, with only a small pith; the leaves were round it, without any order, very thick set, having no foot-stalks; being about two inches and an half long, and about one third of an inch broad near the farther end, where broadest; smooth, hard, and of a brownish or dirty green colour: on the top of the branch comes the fruit, which is surrounded by three or four twigs overtopping it, and with their leaves almost hid in it: it is about five inches long, and is made up of many scales, hard and red, inclosi g one another; the lowermost and outwardmost being very short, the innermost four inches long, each of t em ending in a point; some scales, having on their outsides a gummy piece: In the middle of these scales were the first rudiments of many seeds, the same not being fully ripe; each of which is set about with a great quantity of yellow, fine, silken down, about three quarters of an inch long, having a stylus, or string, two inches long, and yellowish membranes inclosing the stylus and tomentum; being feathered at top for their better dispersion, in order to propagate themselves. Philos. Trans. N°. 198.

PINE-*apple*, a delicious fruit, called by authors *ananas*. See the article ANANAS.

There are several varieties of it, but the principal are five: 1. The oval *pine*-apple, with white flesh. 2. The pyramidal kind, with yellow flesh. 3. The smooth-leave l kind. 4. The shining-leaved kind, with scarce any spines on its edges. And, 5. The pyramidal olive coloured kind, with yellow flesh. There are a multitude of other varieties of less note, and probably there might, by proper management in the sowing, be raised as many kinds as we have of apples and pears in our orchards.

The plant grows wild in vast abundance in many parts of Africa, and has been long cultivated in the hotter islands of the West Indies, where they are now very plentiful and very fine. It is now some time also since it has been introduced into the gardens of Europe, where, with proper management, it succeeds very well. There is an opinion, that there are none raised so good from the American plants, as from those originally propagated by M. la Cour of Leyden, the first who ever succeeded in the bringing it to fruit in Europe; but this is an error, occasioned by some of the indifferent kinds having been at first frequently sent over from America; but of late we have had much finer from thence than ever M. la Cour knew.

The first sort is the most common in Europe, but the second is greatly preferable to it; being much larger and better flavoured, and the juice being less astringent, the fruit may be eaten with less danger in large quantities. This usually produces six or seven suckers also under the fruit, from whence it may be propagated, and therefore is the most fit for culture of any. The third sort is propagated merely as a curiosity, the fruit being much inferior to that of the others. The fifth is the most valuable of all, and is had from Barbadoes and Montserrat. The fourth is what is called in America, the *king-pine*; they are propagated by planting the heads or suckers: these are to be set in pots of five or six inches over at the top, filled with good fresh light earth, mixed with a little rotten dung; this mixture must be often turned, to make it mix the more perfectly, and the plants, when set, must have a little water, to settle the earth to their r ots; and the pot then plunged into a well-tempered bed of tanners bark. See the article HOT-BED.

They muſt have frequent but gentle waterings, and if the heat of the bed decreaſes, new bark muſt be mixed with the old, which will make it ferment again, and renew the heat.

In Auguſt and September, as the nights grow cool, the covering muſt be increaſed over the glaſſes; and towards the latter end of October, the plants muſt be removed out of the bark-bed into the ſtove.

During the winter ſeaſon, great care muſt be taken to regulate the heat in the ſtove, never ſuffering the ſpirit in the thermometer to fall below the degree for *pine* apples in the botanical ones, nor ever to riſe above five degrees more. They muſt be frequently watered, and the water uſed to them muſt always be firſt kept four and twenty hours in the ſtove.

In the beginning of February the plants will ſhew in their center their bud for the fruit; and in the middle of February the hot-bed of tanners bark muſt be prepared, that the heat of it may be in ſome meaſure over before the plants are ſet into it, which muſt be about the middle of March. The pots muſt be at firſt but half way buried in the bark; about a month after this they ſhould be raiſed up, and the bed ſtirred about with a fork; and after this, the pots are to be plunged into it, up to their rims. They are now to have frequent waterings during the ſummer ſeaſon; they are to be frequently watered, and ſhaded from the violence of the ſun, in very hot days, and the glaſſes are now and then to be raiſed a little, to give them air; the bark muſt be ſtirred from the bottom, and, if neceſſary, a little freſh bark added to it to encreaſe the heat; and this may be repeated two or three times in a ſummer. The time of the ripening of the fruit in greateſt perfection, is from the beginning of July to the end of September: they are known to be ripe by their ſtrong and agreeable ſmell, and by gently preſſing the protuberances with a thumb and finger; which, if they feel ſoft and give way, afford certain ſigns that the fruit is ripe. When ripe, it ought to be gathered; for, in a day or two, it loſes its high flavour: and when gathered, they ought to be eaten at the utmoſt within twenty-four hours. It is always beſt to keep the crown on till the time of eating the fruit.

Many make their hot-beds for the cultivating this fruit in frames of about three feet deep; but it is a much better way to erect a ſtove on purpoſe, with bark pits in it for the hot-bed. Theſe ſtoves need not be higher than to admit a perſon to walk upright on the back ſide, and may be brought ſloping down at the front till the glaſs touches the bed. *Miller's* Gard. Dict. See the article STOVE.

PINE-*apple*, in metallurgy, a word uſed to expreſs a ſort of mould, uſed in the refining ſilver. It has this name from its ſhape, reſembling the fruit of that name.

When the refiners have taken the mixture of the ſilver and mercury together out of the cauldron, and ſtrain it through two coarſe wetted cloths, to make it the thicker, they then beat it with a ſort of battledoors, to drive out yet more of the quickſilver; and ſtraining it again after this, they take out the remaining thick amalgame, and forming it into little pellets, they put theſe carefully into the moulds called *pine-apples*, preſſing them down. The amalgame, when put into this veſſel or mould, is uſually ſo rich as to be about one fifth ſilver.

The manner of diveſting this of the quickſilver afterwards, is by means of fire; in which the quickſilver riſes in vapour, and the ſilver is left pure behind: but the careleſsneſs of the workmen in doing this, and particularly the uſing bad veſſels, or the not luting them cloſe, cauſes a waſte of this mineral greater than could be conceived. Alonſo tells us, that in the city of Potoſi alone, at the time of his writing, when the trading in metals ran but low, above thirty thouſand pieces of eight were waſted in quickſilver that was loſt one year with another. To prevent this, they then principally ſtudied the means of keeping the ſilver as dry of quickſilver as they could, in the *pine-apple*; but it then holding four fifths of the whole maſs in quickſilver, the great waſte was in the ſeparating it afterwards. *Alonſo Barba* de Metal.

PINE-*ſalt*, a name given to a preparation of the bark of the *pine*-tree, uſed as a ſort of ſeaſoning to food in the manner in which we uſe ſalt.

The Laplanders are very fond of this, and the manner of their preparing it is given in Scheffer's hiſtory of that country: they peel off the bark from the lower part of the bodies of thoſe trees, and ſeparating the outer rough part, they take the inner bark, which they carefully divide into its ſeveral thin coats: when they have thus reduced them to as thin pieces as they can, they expoſe them to the ſun in their ſummer months to dry, and when thoroughly dried, they tear them into thin and narrow ſlips, and put them up in boxes made of the outer bark of other trees freſh taken off. They bury theſe boxes in deep holes dug in the ſands, and let them remain thus one day; on the day following they bring together a number of ſtumps of trees, and other wood, and laying them over the place where the bark is buried, they ſet them on fire: the next day they take out their buried boxes, and the heat having penetrated ſo deep into the earth in a mild degree, the bark is found to have been greatly affected by it, and to have received a red colour, and a very agreeable flavour, ſomewhat ſweetiſh. This is their general ſauce; they eat it with all their food, as we do ſalt, but it has ſo little of the nature of ſalt, that the name is but ill adapted to it.

There is another vegetable ſubſtance, which, tho' of a diſagreeable taſte to us, yet cuſtom teaches them to be fond of. This is the angelica petroſa: they cut the large ſtalks of this plant before it runs to ſeed, and roaſt them; they eat this in conſiderable quantities with their *pine-ſalt*, and eſteem it not only an agreeable, but a more than ordinarily wholeſome ſort of food.

PINGUICULA, *butterwort*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of a ſort of bilabiated form, in ſome degree reſembling the violet flower, and ending in a ſort of heel: the piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower; and finally becomes a fruit or capſule, containing a great number of ſmall ſeeds affixed to a placenta.

The ſpecies of *butterwort*, enumerated by Mr. Tournefort, are theſe: 1. The common *butterwort*, called alſo *mountain ſanicle*, and *Yorkſhire ſanicle*. 2. The white flowered *butterwort*, with a very ſmall flower and ſhort heel. 3. The purple *butterwort*, with a very large flower and a very long heel. 4. The ſmaller *butterwort*, with a fleſh-coloured flower. *Tourn.* Inſt. p. 167.

The characters of this genus, according to Linnæus, are, that the cup is a ſmall acute labiated perianthium, which remains when the flower is fallen; its upper lip being erect and trifid, its lower reflex and bifid: the flower is labiated, and made up of a ſingle petal: the longer lip is ſtrait, obtuſe, trifid, and laid flat; the ſhorter is bifid, more obtuſe, and ſpread more open: its nectarium is in the figure of a horn, and is produced from the bottom of the petal: the ſtamina are two cylindric filaments, crooked, and inclined upwards, and ſhorter than the cup: the antheræ are roundiſh: the piſtil has a roundiſh germen, a very ſhort ſtyle, and a ſtigma compoſed of two lips; the upper of which is large, plain, bent backward, and covers the antheræ; the lower is very narrow and ſhort, and is placed erect, and is bifid: the fruit is an oval-ſhaped capſule, compreſſed at the top, and naturally opening there, and containing only one cell, full of very numerous and cylindric ſeeds placed looſe in it. *Linnæi* Genera Plant. p. 5.

PINHONES, the name by which the Portugueſe call the purging nuts, as they are called, of America; the fruit of a great ricinus, or palma-chriſti. *Piſo*, 169.

PINIROLO, in zoology, the name of a bird of the tringa kind, ſomewhat approaching to the land-piper, but larger. Its beak is a little more than a finger's breadth long, and black: it is of a mixed cheſnut colour, and brown on the back; and its belly and breaſt are perfectly white: it is common in the Italian markets, and very much reſembles the common tringa: *Ray's* Ornithol. p. 223.

PINK, *caryophyllus*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is compoſed of ſeveral petals, diſpoſed in a circular form, and produced out of a tubular cup, of a cylindric ſhape and membranaceous ſubſtance, and ſcaly at the bottom. The piſtil ariſes alſo from the ſame cup, and finally becomes a cylindric fruit; which, when ripe, opens at the ſummit, and is ſurrounded by the cup, and filled with flat, and, as it were, foliaceous ſeeds, which adhere to a placenta See Tab. 1. of Botany, Claſs 1.

The ſpecies of *caryophyllus*, enumerated by Mr. Tournefort, are theſe: 1. The common great red *pink*. 2. The broader-leaved great *pink* 3. The great *pink*, with variegated flowers. 4. The great *caryophyllus*, with very double flowers, of a variegated red and white 5 The great very double *caryophyllus*, with ſcarlet, red, and white flowers. 6. The great very double, deep red *caryophyllus*, with three white pointals in the middle. 7. The great round-flowered *caryophyllus*, with ſcarlet and white flowers. 8. The great *caryophyllus*, with blackiſh, purple, and ſnow-white flowers. 9. The great double *caryophyllus*, with violet and white flowers. 10. The great double *caryophyllus*, with vermillion and white flowers. 11. The common, tall, variegated, double *caryophyllus*. 12. The great white *caryophyllus*. 13. The red and blood-coloured *caryophyllus*. 14. The white *caryophyllus*, with dots and lines of red. 15. The double *caryophyllus*, with purpliſh red flowers. 16. The fleſh-coloured and white double *caryophyllus*, with ſpots and lines of red. 17. The double *caryophyllus*, with every leaf of the flower half white and half red, and variegated with red ſpots. 18. The crimſon and ſnow-white *caryophyllus*. 19. The great double whitiſh *caryophyllus*, with deep purple ſpots. 20. The great bright white and ſcarlet *caryophyllus*. 21. The great round-flowered double *caryophyllus*, of a deep red and white 22. The great double fleſh-coloured and white *caryophyllus*. 23. The great double white-flowered *caryophyllus*, with a mixture of bright red. 24. The great double *caryophyllus*, with duſky white flowers, and ſpots of a ferrugineous colour. 25. The great broad-leaved *caryophyllus*, of the colour of the peach-bloſſom. 26. The great double purple *caryophyllus*, with ſpotted leaves. 27. The great purple *caryophyllus*, with ſpots of a deeper purple. 28. The greeniſh-flowered *caryophyllus* 29. The leſſer white *caryophyllus*, with lines of ſcarlet or violet colour. 30. The red-lead-coloured *caryophyllus*, with flowers white in the center. 31. The double violet-coloured *caryophyllus*. 32. The double orange-coloured

coloured *caryophyllus*. 33. The dappled *caryophyllus*, of a white and orange colour 34. The middle-ſized *caryophyllus* altilis, with pale violet-coloured flowers. 35. The ſmall *caryophyllus* altilis, with pale yellowiſh flowers. 36. The little variegated *caryophyllus* altilis. 37. The common ſingle garden-*caryophyllus*, with large flowers. 38. The common garden ſingle *caryophyllus*, with fleſh-coloured flowers. 39. The ſingle garden-*caryophyllus*, with variegated flowers. 40. The great wild *caryophyllus*, with variegated flowers. 41. The common double ſmall garden-*caryophyllus*. 42. The procumbent garden-*caryophyllus*, with double-red flowers, ſpotted with white. 43. The double-jagged garden-*pink*. 44. The double-jagged garden-*pink*, with fleſh-coloured flowers. 45. The garden-*caryophyllus*, with very finely divided flowers. 46. The fleſh-coloured finely divided garden-*caryophyllus*. 47. The white finely divided garden-*caryophyllus*. 48. The white ſcentleſs jagged-flowered wild *caryophyllus*. 49. The ſweet-ſcented jagged-flowered wild *caryophyllus*. 50. The white-flowered ſweet-ſcented jagged-flowered wild *caryophyllus*. 51. The jagged-flowered wild *caryophyllus*, with ſweet-ſcented ſtamina. 52. The jagged-flowered ſweet-ſcented *caryophyllus*, without ſtamina. 53. The cretic ſhrubby *caryophyllus*. 54. The ſingle *caryophyllus*, with ſmall pale-red flowers. 55. The ſmall ſingle *caryophyllus*, with ſpotted flowers. 56. The procumbent broad-leaved ſingle *caryophyllus*. 57. The ſingle procumbent narrow-leaved *caryophyllus*. 58. The double purple *ſweet-william*, or *caryophyllus barbatus*. 59. The double white *ſweet-william*. 60. The roſe coloured *ſweet-william*. 61. The ſingle broad-leaved *ſweet-william*, with fleſh-coloured flowers. 62. The ſingle broad-leaved *ſweet-william*, with purple flowers, and with variegated leaves. 63. The purple broad-leaved ſingle *ſweet william*. 64. The white broad-leaved ſingle *ſweet-william*. 65. The ſingle broad-leaved *ſweet-william*, with variegated flowers. 66. The pale red-flowered narrow-leaved *ſweet-william*. 67. The deep red-flowered narrow-leaved *ſweet-william*. 68. The narrow-leaved *ſweet-william*, with milk white flowers, with red ſpots. 69. The narrow-leaved *ſweet-william*, with white flowers with red edges. 70. The narrow-leaved *ſweet-william*, with plain ſnow-white flowers. 71. The narrow-leaved *ſweet-william*, with a few pale-red flowers. 72. The narrow-leaved *ſweet-william*, with purple flowers and white edges. 73. The narrow-leaved *ſweet-william*, with ſnow-white and purple flowers. 74. The wild *ſweet-william*, or common wild *pink*. 75. The wild proliferous, or childing *pink*. 76. The white flowered proliferous wild *pink*. 77. The ſingle-flowered proliferous wild *pink*. 78. The common wild broad-leaved *pink*. 79. The many-flowered mountain-*pink*. 80. The Italian umbellated *pink*, with yellow and ferrugineous flowers. 81. The common narrow-leaved wild *pink*. 82. The wild *pink*, with large ſcentleſs hairy flowers. 83. The little creeping *pink*, with one flower on every ſtalk, called by many the *maiden-pink*. 84. The red wild *pink* of Carynthia. 85. The purpliſh blue woolly or hairy-flowered wild *pink*. 86. The wild *pink* with hairy white flowers. 87. The common little wall-*pink*. 88. The common wild *pink* of the warm climates. 89. The alpine *pink*, with roſe-coloured flower and greeniſh umbilicus. *Tourn.* Inſt. p. 330, ſeq.

PINNA (*Cycl.*)—PINNA, a *fin*, in natural hiſtory, the name of that part of a fiſh which diſtinguiſhes it from other aquatic creatures, no animal but a fiſh having *fins* and wanting legs.

The *fin* is properly a part ſtanding out, or hanging from, the body of the fiſh, and conſiſting of a membrane ſupported by ſeveral rays or oblong bones; which are in ſome hard and firm, and in others cartilaginous.

This definition of a *fin* properly excludes all thoſe other parts of a fiſh which may be prominent from the body, and may be of a membranaceous ſtructure, and even carry the appearance of a *fin*, tho' they have none of the rays or little bony ſubſtances within them, and therefore cannot ſerve the creature in the office of *fins* in ſwimming; for the cartilages or bones, which ſupport the membranes of the *fins*, are what give them their due and neceſſary ſtrength and firmneſs to bear againſt the water for the motion of the body of the fiſh: thoſe other membranaceous appendages to the bodies of fiſhes cannot do this; for wanting the ſupport of theſe rays, the ſimple and ſoft membrane has no more power of moving the water, than the water has of moving it. Hence appears the uſe of the bones or rays, ſupporting the *fins*, and the truth of the definition, that nothing is properly a *fin* which wants them.

The *fins*, by their differences, make very obvious diſtinctions among the ſeveral ſpecies of fiſhes; and theſe differences are, in regard to number, ſituation, figure, and proportion.

The number of the *fins*, including the tail, is very different, in different fiſh. 1. In ſome there is only one *fin* to the whole fiſh. This is the caſe in the ophidium lumbriciforme, and in the muræna. 2. The *fins* are two in number in others, as in the petromyzæ and the like. 3. There are many which have three *fins*; as the conger, the eel, the common ophidium, the greenland whale, the ſea-cow, and the like. 4. Many have four *fins*, of the number of which are the dolphin, the phocæna, and the ſecond kind of the acus Ariſtotelis. 5. Several have five *fins*; as the ammodytes or ſand-eel, the ſword fiſh, the lupus marinus, the mola or ſun-fiſh, and many others. 6. The lump-fiſh gives us an inſtance of ſix *fins*; for the ſeeming firſt *fin*, on the back of that fiſh, is not a real *fin*, but only a cutaneous prominence. 7. Many fiſh have ſeven *fins*; as the gudgeon, the pleuronectes, the cyprinus, the clupea, the coregones, the oſmeri, the ſalmons, the cobites, the eſoces; the cernua fluviatilis, the gaſteroſteæ, the ſpari, the labri, the ſilurus, the mugil alatus, the remora, the capriſcus, the hippurus, the pompilus, and the accipenſer. 8. Many fiſh alſo have eight *fins* each; of this number are ſome of the pearches, the clarea, the cottus, the mugil, the labrax, the ſudis, the mulli, the ling, the trachurus, the ſcyæne, the trachinus, the uranoſcope, and that little fiſh called the *anguella* by the Venetians. 9. The ſcorpæna of Rondeletius gives us an inſtance of the *fins* being nine in number; and, finally, the ſcombri and thynni, give us inſtances of eleven *fins* in the ſame fiſh.

The differences in ſituation are leſs numerous than theſe, as to number, but they are not leſs obvious and eſſential. 1. They are generally placed both on the back and belly, as we ſee in moſt of the ſpecies of fiſhes. 2. They are ſometimes placed only on the back. This is the caſe in the petromyzæ, the acus lumbriciformis, and ſome others. 3. Some have them, on the contrary, only on the belly; of this kind are the Greenland whale, the ſea-cow, and the like: and to this it is to be added, that the back and belly *fins* differ greatly in the ſeveral fiſh, in their being placed more or leſs backward or forward.

The differences of ſhape or figure in the *fins* of fiſhes, are alſo very obvious. 1. They are in ſome nearly triangular, as in the cyprini, and ſalmons, &c. 2. Some few fiſh have them round. And 3. Some have them of an oblong ſquare, or parallellogram figure.

Finally, the difference in proportion is not to be omitted; for they are in ſome much ſhorter and ſmaller than the body; as is the caſe in the generality of fiſhes; but in others they are of an equal length with the body. Of this kind are the pectoral *fins* in ſome of the legyræ, and the ventral *fins* in the mugil alatus of Rondeletius, and other authors. *Artedi*, Ichthyol. p. 4.

Aculei PINNARUM, in ichthyology. Every apophyſis or eminence on the head or body of a fiſh, which is ſo ſharp at the end as to be capable of pricking, is called an *aculeus*; but the *aculei pinnarum* in particular, are thoſe prickly *radii* or bones, which ſerve to ſupport the fins; and being carried out beyond the rim of the membrane, end in ſo many points.

Theſe *aculei* are ſimple cylindric officles, whereas the other officles, which ſuſtain the fins, are leſs rigid, and are bent and not prickly: and theſe are not ſimple, but are compoſed each of two officles cloſely cohering one to another. Many of theſe *radii* are divaricated at their extremity into two, three or more branches; theſe when they are carried out beyond the rim of the membrane, are harmleſs, and are ſeen to be compoſed of two officles, as the body of the radius is. The *aculei* of the back and belly of all fiſhes are ſo far of the ſame nature, that they never ſtand ſingle, as ſome have ſuppoſed them to do in particular inſtances; but they are always connected one to the other at the bottom, by a membrane, tho' that be ever ſo ſmall and low, as in ſome it is ſcarce viſible.

PINNARUM *radii*. See the article RADII *pinnarum*.

PINNA *marina*, in natural hiſtory, the name of a ſhell-fiſh, by the lateſt writers on theſe ſubjects referred to the genus of muſcles. See the article MYTULUS.

This ſhell-fiſh is like the muſcle, held in its place by a number of threads, which proceed from its body, and are fixed to any adjoining ſubſtance, and is one of thoſe fiſh, which, like the muſcle, has a power of ſpinning in the manner of the ſpider and caterpillar. See the article MUSCLE.

The threads which theſe fiſh ſpin, are infinitely finer and ſlenderer than thoſe of the muſcle, notwithſtanding that the fiſh is vaſtly larger; its ſhells being often found two foot long. Theſe threads are indeed ſcarce, leſs fine than the ſingle ſilk threads of the ſilkworm, and like it have in all times been worked into uſe. The fineſt kind of the byſſus of the antients was wrought out of theſe threads, and at preſent they are manufactured at Palermo, and at many other places, into gloves, ſtockings, and other ſorts of wearing apparel.

It is eaſy to conceive, that threads ſo fine as theſe can be of no great ſtrength; but what is wanting in the force of each, is made up in the number of them; which are ſpun by every fiſh, for this is almoſt infinite. They differ in nothing from the threads of the muſcles, beſide their fineneſs and their length; which is in theſe much greater, and therefore makes them greatly the more valuable. They are probably formed in the ſame manner with thoſe of the muſcles; and the *pinna* may be called, by way of diſtinction, the ſilkworm of the ſea; and the muſcle, the caterpillar. See Tab. of Shells, N°. 20. Mem. Acad. Par. 1711.

PINNARUM *dilatator proprius*, in anatomy, a name given by Santorini to one of the muſcles of the face, which he has alſo called *myrtiformis naſi*, and which Cowper has called *depreſſor labii*

labii superioris, sive constrictor alæ nasi, and Albinus the *depressor alæ nasi*. See the article DEPRESSOR.

PINNATED *leaf*, among botanists. See the article LEAF.

PINNATIFID *leaf*, among botanists. See the article LEAF.

PINNATUS, in heraldry, a term used by the Latin writers on these subjects, to express that sort of line in arms which is called by our heralds the *embattled line*, or *crenelle*. It is also called by some *linea pinnis asperata*, and by Sylvester Petro Sancto *murales pinnulæ*. When this line is only embattled on one side, it is properly expressed by this word; but when it is embattled on both sides, as in some arms, it is called *bretesse* and *contre bretesse*. See the article EMBATTLED.

PINT (*Cycl.*)—In the English beer measure, the *pint* is the eighth part of a gallon; consequently contains 35¼ cubical inches. Tr. Pract. Geom. p. 117. See the article GALLON.

As to the *pint* used in Scotland, there are different opinions concerning the number of cubical inches it contains. Dr. Gregory makes them 109; others, from several careful mensurations of the standard kept at Edinburgh, make the Scotch *pint* to contain 103$\frac{1}{10}$; and those in common use are said to contain betwixt 105 and 106 cubical inches. Another experiment was made with a cask, which was found to contain 46⅞ Scotch *pints*, and 18$\frac{1}{16}$ English ale gallons. Supposing this mensuration just, the Scotch *pint* will be to the English ale gallon as 289 to 750; and if the English ale gallon be supposed to contain 282 cubical inches, the Scotch *pint* will contain 108.664 such inches. Tr. Pract. Geom. p. 114.

The Paris *pinte* is nearly equal to an English wine quart. Tr. Pract. Geom p. 117.

PINTADO, or AFRA AVIS, in natural history, a name given by the antient Roman authors to the Guinea hen.

Varro, Columella and Pliny, with many others, make the *pintado* and the *meleagris* the same species of bird; but Suetonius, Scaliger, and some others, are of opinion, that the antients meant two very different birds by these names; and the latter of these authors endeavours to bring Varro over to his side, by altering the pointing in the passage of that author which relates to it.

The bird is of late become very common in England, and breeds with us in great plenty. The hen lays her eggs and sits upon them in the same manner with the common hen; but the eggs are smaller and not so white as the hens eggs, but have a tinge of flesh colour and some black spots. They are not so tame and domestic as our own fowls, and particularly they will not lay in houses; but get into the hedges and among bushes, where they lay and hatch; but this is the occasion of great loss among them, the wild vermin destroying a great part of their young brood. The female also is less careful about the great business of hatching and taking care of them, than any other bird we are acquainted with. She will often leave her nest when the eggs are near hatching, and never return to it again; and often will desert the young as soon as hatched, if she remains at her nest till that time. The best method, therefore, is to set other fowls upon the eggs of this kind. The young fowls of this kind are very beautiful; they look like so many partridges. Their beaks and legs are red, and their whole plumage is at that time of the colour of the partridge. See Tab. of Birds, N°. 21.

The hen, if her nest is found, and the eggs at times taken away, but so as always to have one there, will continue to lay till she has deposited an hundred, or sometimes an hundred and fifty eggs, which are very well-tasted. This is a very active and sprightly bird, and of an unquiet and troublesome disposition to the owner. It runs very swiftly in the manner of the quail and partridge; but its wings are short, and it is not made for flying; yet at night it will not roost among other fowl, but gets upon a house or tree, or any other high and safe place. The cry of the bird is sharp and disagreeable to many ears, and it is almost continually making it. It is of a quarrelsome disposition, and will be mistress of the yard: its agility, and the sharpness of its beak, generally obtain it the victory with what ever bird it fights.

The *pintado* is so common in America, that many have supposed it native there; but this is not the case. The origin of the bird is in Guinea, and the first that were ever brought into America, were brought in the year 1508, with the cargoes of negro slaves. The Spaniards neither at that time nor ever since, have attempted to tame them, or render them a domestic useful bird, but let them go loose and wild in the savanhas; where they have increased to such prodigious numbers, that they may well appear native, and are seen in vast flocks together, and are called *marroon pintades*, by the Spaniards and French. Observ. sur les Cout. de l'Asie, p. 190.

PINUS, the *pine-tree*. See the article PINE.

PIONY, *pæonia*, in botany. See the article PÆONIA.

The several sorts of this plant are all very hardy, and will grow in almost any soil and situation; they are propagated by parting the roots, which multiply very fast. They should be planted in August, or the beginning of September, and will then flower the succeeding summer. The off-sets should not be too small, and should all have a fair bud or eye. The single kinds may also be propagated by sowing their seeds in August in a light earth, and managing them in the method of all other seedling plants. There may probably be some good varieties of the flowers produced this way. The single Portugal *piony* is of so sweet a smell as to deserve a place in any garden, tho' but a single flower. *Miller's* Gard. Dict.

Piony-root, is a celebrated medicine in nervous cases. We have instances well attested, of epilepsies cured by it alone. It is good also in all disorders of the head, in hysteric complaints, and obstructions of the viscera.

PIPE (*Cycl.*)—The Turkish *tobacco-pipe* is very long, the tube is made of wood or reed, and the bowl of earthen ware; those they carry with them when they travel, they have made in two or three joints, to put into a bag; they cover the tube sometimes with cloath, and dip it in water to make it smoak cool. *Pocock's* Egypt, p. 186.

PIPE, in mining, is where the ore runs forwards endways in a hole, and doth not sink downwards or in a vein. *Houghton's* Compl. Miner in the Explan. of the Terms.

PIPER, *pepper*. Baldæus tells us, that the *pepper* thrives best in the coolest and most shadowy places, and that the plant has a weak stem like that of the vine, which must be supported by something to climb upon. These commonly grow about six clusters on every branch, each cluster is a foot long, and in colour like unripe grapes. They gather it while green in October and November, and expose it to the sun to dry, by which means it grows black in a few days. *Baldæus* de Ind. Orient. p. 99.

PIPER *chiapæ*, in botany, a name given by some authors to the clove berry-tree, or *cassia caryophyllata*. *Redi*, Lat. p. 132.

PIPER *Jamaicæ*, the *pepper-tree* of Jamaica. See the article PIMIENTA.

PIPER *nigrorum*, *negro pepper*. The plant called at present by this name is the capsicum, or Guinea *pepper*, a remarkable herb, bearing large pods as red as coral, of which the Cayan butter is made in America. But this is not the plant that was antiently known by this name Avisenna and Serapion, both mention a plant which they call *fulful alsuaden*, the English of which is, the *pepper* of the black people. But this was properly what has been since called the *Ethiopian pepper*; a sort of hot seeds approaching to the nature of the common *pepper*, and contained several together in pods. Avisenna tells us, that the plant properly and rightly called *piper nigrorum*, had pods like those of the kidney-bean, which were of a black colour, and that the seed was hot and biting to the taste like *pepper*. There was also another thing called by the same name, that is, the *zelem* of these authors; this was brought from Barbary, and was a fruit of a high flavour, of the bigness of a vetch, and was yellow on the outside and white within. Serapio absolutely distinguishes this by the name of *zelem*, from the other *piper nigrorum*, properly so called; yet Guillandinus has been the occasion of many errors in regard to these fruits, by attributing to the *zelem* the things which that author expresly says of the other *piper nigrogrum*, or *Ethiopian pepper*: it is not easy from the accounts we have left, to say what it is; but they have left description enough of it for us to say what it is not, and to find that they have all been mistaken, who have supposed it to be either the root tarsi, or the bulbus of the Arabians, which last was as large as a pear.

PIPER *tavasci*, in botany, the clove-berry-tree, or *cassia caryophyllata*; a tree whose bark is used in medicine. *Hernand.* p. 30.

PIPERAPIUM, an old name of a plant found in Apuleius, and said to have its name from its heat to the taste; which was so offensive to the bees, that if a piece of it were hung up in their hive it would drive them all out.

This is a very strange account, and as we meet with nothing to countenance it in any other author, there is reason to suspect it to be an error; and there seems this foundation for it. The acorus root is said by Dioscorides to be the root of a plant allied to the papyrus, or paper reed of the river Nile; and is thence called by that author *papyraceus*. Avisenna and Serapion copy this, and liken the acorus plant to the papyrus; but in all the copies of the Greek author, it is often found written πεπεράκιον. This word *peperacion*, may have been formed by Apuleius into *piperapium*, by way of amendment, and all the rest might be occasioned by this.

PIPERITIS, in botany, a name given by some authors to the *momordica*, or male balsam apple. *Tourn.* Mat. Med. p. 357.

PIPERIVORA *avis*, in zoology, a name given by some authors to the *toucan*, or Brasilian magpye, from its feeding on pepper. *Ray's* Ornithol. p. 88. See the article TOUCAN.

PIPRA, in zoology, a name given by Aristotle, and other antient writers, to the *picus varius major*, the great spotted wood-pecker, or witwall. See the article PICUS.

PIQUE, in natural history, a name given by the Spaniards to an insect of the size of a flea, called by the Indians *tung*. It is common in the East and West Indies, and eats its way into the flesh under the nails, &c. See the article TUNG.

PIQUETTE, among the florists, a term used for a certain sort of carnations, which have always a white ground, and are spotted, or as they call it, pounced with scarlet, red, purple, or other colours.

PIQUITINGA, in zoology, the name of a fmall American river-fifh. It feldom exceeds two inches in length: its mouth appears very fmall, but it can at pleafure open it to a great width: its eyes are very large and black, with a filvery iris: it has fix fins befides the tail, which is forked; its head is of a filvery white: its back olive colour, and its belly and fides are covered with filvery fcales; the fins are all white, and the fide-lines are broad, and very bright and fhining. *Marggrave*'s Hift. Brafil.

PIRA-*aca*, in zoology, a name by which Marggrave and fome other authors have called a little horned fifh of the Weft Indies, called by Clufius and others, the *monoceros pifcis*, or unicorn fifh. *Willughby*'s Hift. Pifc. p 150. See the article MONOCEROS.

PIRA-*acangata*, in zoology, the name of a Brafilian fifh, refembling the perch in fize and fhape. It is of a fmall fize, feldom exceeding four or five inches in length: its mouth is fmall: its tail is forked; and it has on the back only one long fin, which is fupported by rigid and prickly fpines. This it can deprefs at pleafure, and fink within a cavity made for it in the back. Its fcales are of a filvery white, but have an admixture of a fine yellow and reddifh glofs, efpecially on the back: the fides are more purely white, and the belly is of a fomewhat bluifh green, mixed with the white: the back fin is very pellucid, and of a filvery white, and is variegated with brown fpots: the fide fins are white, and the belly ones, and the end of the tail, are blue. It is a wholefome and well-tafted fifh. *Marggrave*'s Hift. Brafil. *Willughby*'s Hift. Pifc. p. 338.

PIRA *bebe*, in zoology, a name ufed by fome authors for the *milvus*, or kite-fifh. *Dale*, Pharm. p. 376.

PIRA *coaba*, in zoology, the name of an American fifh of the truttaceous kind, much efteemed for the delicacy of its flavour. It grows to about twelve inches in length: its nofe is pointed, and its mouth large; but without teeth: the upper jaw is longer than the other, and hangs over it in form of a cartilaginous prominence: its eyes are very large, and its tail forked: under each of the gill-fins it has a beard made of fix-white filaments, and is covered all over with filvery fcales. *Marggrave*'s Hift. Brafil.

PIRA-*jurumenbeca*, in zoology, the name of a Brafilian fifh, called by many the *bocca molle*. It lives in the muddy bottom of the American feas, and is a long-bodied not flatted fifh. It grows to a vaft fize, being fometimes caught of nine, and fometimes even of ten or eleven foot long, and two foot and an half thick. It has one long fin on the back, the anterior part of which is thin and pellucid; and has a cavity on the back, into which the creature can deprefs the fin at pleafure: its tail is not forked: its fcales are all of a filvery colour and brightnefs, and moderately large: it has a greenifh caft on the back, mixed with a fhade of yellow; and it has a line running along the middle of each fide, of the fame filvery hue with the reft of the body, but raifed above the common furface of the part. It is a very well-tafted fifh. *Marggrave*'s Hift. Brafil.

PIRA-*pixanga*, in zoology, the name of a Brafilian fifh of the turdus or wraffe kind, and called by fome the *got-vifch*. Its ufual length is four or five inches. its mouth is confiderably large, and furnifhed with very fmall and fharp teeth: its head is fmall, but its eyes large and prominent: the pupil of a fine turgoife colour, and the iris yellow and red in various fhades: the coverings of the gills end in a triangular figure, and are terminated by a fhort fpine or prickle: its fcales are very fmall, and fo evenly arranged and clofely laid on the flefh, that it is very fmooth to the touch: its tail is not forked, but rounded at the end: its whole body, head, tail, and fins, are of a pale yellow, variegated all over with very beautiful blood-coloured fpots; thefe are round, and of the bignefs of hemp-feed on the back and fides, and fomething larger on the belly: the fins are alfo fpotted in the fame manner, and are all marked with an edge of red. It is caught among the rocks, and about the fhores, and is a very well-tafted fifh. *Marggrave*'s Hift. Brafil.

PIRANHA, in zoology, a name given to the American fifh more commonly known by the name *piraya*. *Marggrave*'s Hift. Brafil. See the article PIRAYA.

PIRAQUIBA, or IPIRAQUIBA, in zoology, a name originally Brafilian, by which fome authors exprefs the *remora*, or fucking fifh. *Marggrave*, 180.

PIRATIA-*pua*, in zoology, the name of an American fea-fifh, which grows to a very large fize, and, while young, is eaten and accounted a delicacy; but, when full grown, is too coarfe, rank, and ftrong. Its jaws are both well armed with teeth; the under all the way on both fides, the upper only in the middle on each. The lower jaw is fomewhat longer than the upper, and the mouth very large. It is of an oblong and rounded body. Its back is a little prominent, but its belly altogether flat and even. It has fix fins befides the tail, which is made of a very large fin, of a fomewhat fquare figure, and is not at all forked. It is all over of a dufky orange colour, but more obfcurely fo on the back than elfewhere; and its fides are variegated with grey fpots, fo difpofed as to reprefent a fort of network. *Pifo*'s Hift. Brafil.

PIRATIAPIA, in zoology, the name of a Brafilian fifh, approaching to the nature of the turdus or wraffe. Its body is oblong, not flatted, and very thick. It is a large fifh, and fometimes grows even to fifty pound weight. Its lower jaw is confiderably longer than the upper, and its teeth are very fharp. Its mouth and tongue are red on the infide, and its eyes are large and prominent. It has only one long back fin, the anterior rays of which are prickly, the hinder fmooth. Its tail is not forked, its fcales are fmall, and its back and belly are of a fine bright red. Its fides of a filvery grey, with a dufky caft. It is all over fpotted alfo with the fame colour in large round fpots. The fins are all red, with a line of white and a fringe of black at their edges. It is a very delicate and valuable fifh *Marggrave*'s Hift. Brafil.

PIRAUMBU, in zoology, the name of a Brafilian fifh, fomewhat approaching to the nature of the turdus, and called by the Portuguefe *chayquarona*. It is of the figure of the carp, and its ufual length is fix or feven inches, and its breadth in the broadeft part about three inches; but gradually diminifhing to the tail. Its eyes are large and prominent. Its mouth like that of the carp. It has two fins on the back. Its fcales are very broad, of a filvery whitenefs, with a fmall admixture of yellow. Its tail is forked The upper half of every fcale is, however, brownifh, and the fins are all grey. Its belly and the under part of the head, are of a fine filvery white. It is caught among the rocks, and near fhores, and is a well-tafted fifh. *Marggrave*'s Hift. Brafil.

PIRAYA, in zoology, the name of a fifh caught in the American rivers. There are two kinds of it: the one growing to a foot long, and very broad in proportion; with a hunched back, and lips that cover its mouth clofely and hide its teeth: its head is blunt and fhort, and its back and fides of a pale bluifh grey, and its belly of a dufky yellow: this loves the muddy bottoms of rivers. The other is much of the fame fize, but has two fins on his back, whereas the other has but one; and has a fine yellowifh and reddifh caft mixed among the bluifhnefs on the back, and its belly of a fine clear and ftrong yellow, between a gold and a faffron colour: this loves the fandy bottoms of rivers. There is alfo a fmaller fpecies of this: all three are eatable fifh. *Marggrave*'s Hift. Brafil.

PIRIT, in natural hiftory, a name given by the people of the Philippine iflands to a peculiar fpecies of fparrow, which is very common with them. It is much fmaller than our common fparrow, and feeds only on the feeds of the canary-grafs, which is very commonly wild there.

PISCES *(Cycl.)*—PISCES, *fifhes*. According to the new Artedian fyftem, *fifhes* in general are divided into five diftinct orders. The generality of fifhes have the tail placed perpendicularly, but a few of them have it horizontally. Of thofe which have the tail perpendicular, fome have the rays of the fins bony; and thefe either have the gills covered with a membrane, containing feveral bones, or they have no fuch membrane: of thofe which have this membrane, with the bones over the gills, fome have the rays, tho' bony, yet not pungent; thefe are called the *malacopterygii*, or the foft-finned fifhes. Others have them with the rays prickly; thefe are the *acanthopterygii*, or prickly-finned fifhes. Thofe which have no bones in the membrane over the gills, make only one genus, and are called the *branchioftegi*. The other kind, which have not bony, but cartilaginous rays in the fins, are called *chondropterygii*. And finally, thofe *fifh* which have the tail placed not perpendicularly, but horizontally, are called *plagiuri*. See MALACOPTERYGII, *&c.*

The *fifh* thus conftituting the order of the *malacopterygii*, are again divided into feveral feries. 1. Thofe which have only one fin on the back, and that placed nearly the middle of the back. 2. Thofe which have one fin placed in the middle of the back, and another ftanding farther behind. 3. Thofe which have only one fin on the back, and that placed far backwards. 4. Thofe which have one or more fins running all the way down the back. 5. Thofe which have one long back fin, fcarce difcernible from the tail. 6. Thofe which have either only one very fmall fin on the extremity of the back, or have no fin at all there. Thefe are the principal diftinctions of the *malacopterygii*.

The *acanthopterygii* are divided only into two feries: the one confifting of thofe whofe head is fmooth; the other of thofe whofe head is rough.

Artedi has given a very fhort definition of a fifh, which fevers it from all other creatures; and feparates from the fifh kind many creatures which fome authors have confufedly treated of among them, as properly of the fame clafs of animals The definition is this: *A fifh is a creature having no legs, and always having fins.* There is no other aquatic animal which has not legs, and has fins properly fo called; and it is very improperly, that creatures, wanting the characters of this definition, are by fome ranked among fifhes; as the infects which have legs, and the ferpent kind, which have no fins. The definition may be rendered longer and more exprefs in the following form: A fifh is an animal having fins, having no legs, always refpiring either by means of lungs or gills; inhabiting the waters, except on extraordinary occafions; and moving itfelf either folely by its fins, or by the additional help of a flexuous motion of the body, fometimes coming out of the water on the earth; and fometimes flying or rifing into the air, and continuing

tinuing there some time, carrying itself along by means of the pectoral fins. The last quality belongs only to the flying fish, and a very few others. *Artedi* Ichthyology, p. 1.

Piscis *fossilis*, in ichthyology, a name given by Jonston to a kind of the cobitis, found buried in the sand, and dug out by the people of many parts of Germany for food. It is called by many authors the *mustela fossilis*, and by some the *pœcilia*. It is properly a species of cobitis, and is called by Artedi the *bluish cobitis*, with five longitudinal black lines on each side of the body. *Artedi*, *Jonston*, de Pisc.

Piscis *sancti petri*, in ichthyology, a name given by Jovius and some other authors to the faber or John Doree. It is properly a species of zeus. See Zeus.

PISCIVOROUS *animals*, are such as feed on fish. See the article Bird.

PISMIRE, in zoology, See Formica.

PISONIA, in botany, the name given by Plumier, in honour of Piso, to a genus of plants, called by Vaillant *pentagonotheca*. The characters are these: it produces separate male and female flowers; in the male flower the cup is erect, very small, and divided into five segments: the flower is of a funnel-shape, the tube is short, and the mouth very wide: it is lightly divided into five segments, and lies open: the stamina are five pointed filaments, longer than the flower: the apices are simple. In the female flower, the cup is the same as in the male; but it stands on a germen: the flower is the same as in the male: from the germen there arises a single, erect, cylindric style, which is longer than the flower, crowned with five oblong stigmata: the fruit is an oval capsule, composed of five valves, and having an obscurely pentangular appearance, but having only one cavity within: the seed is single, smooth, and of an oval or oblong figure. *Linnæi* Gen. Pl. p. 474. *Plumier*, Gen. 11. *Houston*, 13. *Vaillant*, Act. Germ.

PISSASPHALTUM, in natural history, the name of a genus of fossils, the characters of which are these: They are fluid mineral bodies, of a somewhat thick consistence, dusky, and opake; of a strong smell, and readily inflammable, but leaving a residuum of greyish ashes after burning.

There are three known species of this genus: 1. A thinner blackish kind, called *oleum terræ*. 2. A thicker black one, called *pissclæum Indicum*, or Barbadoes tar. And, 3. A black and viscous one, called simply *pissasphaltum* in the shops. See the articles Oil *of the earth*, and Pisselæum.

Pissasphaltum is as tough and viscous as bird-lime, and of the same consistence when old. It very much resembles the common black pitch, when softened a little by heat; and has been generally thought to have something of the smell of that substance: but this seems to have arisen from its being too frequently adulterated by mixing pitch with it, and the true genuine substance has no other smell than the rank one of all the bitumens, which somewhat resemble that of oil of amber. It is produced in several parts of the world, and there are large quantities of it in Germany, in Persia, and in France. It yields a limpid oil by distillation, which very much resembles the native petroleum, and is too often sold with us under this name, being annually imported in large quantities from those parts of Germany where it is manufactured, and having itself no particular name in the shops of our druggists. *Hill's* Hist. Foss. p. 422.

Pissasphaltum was much recommended by the antients for external use, as an emollient, maturant and digestive: with this intention it was used in cataplasms, for ripening all sorts of tumors, and against the sciatica and other pains of the limbs. They also had recourse to it for strengthening the limbs, after the reduction of dislocations. It is little used at present, the petroleum being thought very proper to supply its place.

PISSELÆUM *indicum*, in the materia medica, a substance commonly known by the name of *Barbadoes tar*. It is a heavy, thick, and dusky-looking mineral fluid, of the colour and consistence of common treacle, and of a very opake hue; it is of a disagreeable smell, faintly approaching to that of oil of amber, and is very inflammable. It is found trickling down the sides of the mountains at the back of several of our plantations in America, and is in great esteem there for coughs and disorders of the lungs. We meet with very little in England that is genuine, several different sophistications of it being in common use, even upon the spot. *Hill's* Hist. Foss. p. 421.

PISSEROS, the name of an ointment greatly recommended by Hippocrates in many cases, as in burns, fresh wounds, &c. It was made of oil of roses, bees-wax, and pitch, proportioned so as to give the whole a soft consistence. It was of the nature of our modern black basilicon, found a good ointment in many cases.

PISSINUM. Pliny says it was customary for the antients to hold fleeces of wool over the steam of boiling tar, and squeeze the moisture from them, which watery substance was called *pissinum*.

Ray will have this to be the same with the *pisselæum* of the antients; but Hardouin, in his notes on Pliny, thinks the *pisselæum* to have been produced from the cones of cedars. What use they made of these liquors antiently is not known; but it may be presumed they were used in medicine, tho' at present it does not appear they are used at all.

PISSITES, a name given by the antients to a wine impregnated with the virtues of liquid pitch or tar. To prepare it, the tar was ordered to be washed in sea water or brine, and afterwards in fresh water many times; and after a tedious preparation of this kind, two ounces of it were ordered to be put to eight gallons of must, which is to be suffered to work together, and then the clear liquor to be bottled off.

This was accounted a warm wine, very assistant to concoction, and of an absterfive faculty, and a good pectoral: on these accounts it was given in disorders of the breast, and in obstructions of the liver, spleen, and uterus, if not attended with a fever; and was a common medicine in coughs and asthmas, of all kinds.

PISSOCEROS, a name given by the old naturalists to a substance found very frequently in the hives of bees, and consisting of a mixture of propolis and wax. The antients were well acquainted with the use of this substance, which was used for stopping up the cracks and chinks in the hives: they mention, indeed, three sorts of matter used by the bees for this purpose; the metys, the *pissoceros*, and the propolis: but later authors call them all by the general term propolis, the *pissoceros* and metys being only the same substance, mixed with wax in different proportions. This propolis is a resinous substance, of a soft and viscous consistence, collected from the beds of the poplar and other trees. *Reaumur's* Hist. Inf. Vol. 10. p. 84. See the article Propolis.

PISSOSIS, a word used by the old writers on medicine for the depraved appetite of young women about the first eruption of the menses, and of some women with child.

PISTACHIA *trifolia*, in botany, a name improperly given by some authors to the trifoliate American bladder-nut. See the article Staphylodendron.

Pistachias are esteemed restorative, and peculiarly recommended to prevent obstructions of the liver: they are also found of service in nephritic complaints, and are said to be great provocatives to venery: the faculty, however, seldom prescribe them.

PISTANA, in botany, a name by which some authors have called the *sagittaria aquatica*, or water arrow-head. *Ger.* Emac. Ind. 2.

PISTATIO, among pharmaceutic writers, a word used to express that preparation of simples which consists in covering them with, or including them in, a paste, and sending them to a baker's oven till tender throughout. Squills are sometimes prepared thus.

PISTIA, in botany, the name given by Linnæus to a genus of plants, called *kodda-pail* by Plumier; and in the hortus Malabaricus. The characters are these: There is no cup; the flower consists of one unequal petal, which is cucullated and turbinated, with a single, oblique, and long lip, bent and folded at the side; there are no stamina, but six double antheræ grow to the pistil under the stigma; the germen of the pistil is of an oval oblong figure; the style is shorter than the flower; the stigma is peltated, and obtusely divided into six segments; the fruit is a capsule of an oval figure, attenuated at the base, and contains six cells; the seeds are truncated. This genus seems nearly allied to the birth-worts. *Linnæi* Gen. Pl. 438. *Plumier*, 39.

PISTIL, among botanists, the female organ of generation in flowers. It is composed of three parts, the germen, the style, and the stigma: the germen supplies the place of the uterus in plants; its shape is various, but it is always situated at the bottom of the *pistil*, and contains the embryo seeds: the style is a part of various figures also, but is always placed on the germen; in some it is extremely short, in others it seems entirely wanting: the stigma is also of various figures; its place, however, is certain, as it always stands on the top of the style, and if there is no style, on the top of the germen. See the article Generation *of plants*.

PISTIS, in the materia medica of the antients, a name given to the gum bdellium, particularly to that kind of it which was brought from Arabia, and was of a fine yellowish white, and in small round drops, or lumps of a roundish shape, and firm consistence.

PISTOLOCHIA, in botany, a name used by some authors for the plant of which the Virginian snake-root of the shops is the root. *Park.* Theat 420.

PISUM, the *pea*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the papilionaceous kind, and from its cup there arises a pistil, which finally becomes an oblong pod, containing roundish seeds: to this it is to be added, that the stalks are weak and hollow, and the leaves so surround them, that they seem perfoliate; the rest of the leaves are placed two and two upon a middle rib, which ends in a tendril.

The species of *pease*, enumerated by Mr. Tournefort, are these: 1. The large square *pea*, with brown fruit. 2. The large square *pea*, with grey fruit. 3. The large square *pea*, with yellowish fruit. 4. The upright *pea*, with clustered or umbellated pods. 5. The common garden *pea*, with a white flower and white fruit. 6. The common large garden *pea*, with purple flowers. 7. The common large garden *pea*, with variegated flowers and variegated fruit. 8. The great podded garden *pea*. 9. The great *pea*, with the fruit marked with a black

black line. 10. The *pea* with eatable husks. 11. The dwarf *pea* with firm stalks. 12. The angular-leaved *pea*. 13. The garden *pea* with a crooked or foliated eatable pod. 14. The *pea*, with red striated flowers. 15. The field-*pea*, with a greenish yellow fruit. 16. The field-*pea*, with a white fruit. 17. The field-*pea*, with a green fruit. 18. The field-*pea*, with a grey fruit. 19. The field-*pea*, with a blue fruit. 20. The field-*pea*, with black fruit. 21. The field-*pea*, with rose coloured flowers and variegated fruit. And 22. The wild English sea-*pea*. *Tourn.* Inst. p. 394.

PIT (*Cycl.*)—*Brine*-PITS, the name given by the people of Worcestershire and Cheshire, to the wells or *pits* affording the salt water, out of which they extract the salt.

These waters, tho' they all contain salt, yet have other things also in them, and these not in small quantity. They all contain a very large proportion of stony matter; this is common to the whole set, but particular substances beside this are found in the particular *pits*. At Northwich in Cheshire, there are four *pits*, the water of all which stinks very strongly of sulphur, and contains so much vitriol, that it will turn black like ink, with a decoction of galls; yet this is boiled into a very fine and pure kind of salt, common at our tables under the name of basket-salt, and having no such properties.

There is a vast quantity of stony matter precipitated from these pans of *brine* in the boiling them to salt; this is partly saved in small pans set at the side of the boiler, and partly precipitates to the bottom of the pan, where it forms a crust like that at the bottoms and sides of our tea-kettles, which the workmen find it necessary to remove every week; but there is no vitriol or sulphur separated. Phil. Trans. N° 150.

In the country near where these *brine-pits* are, the instruments used in boring often bring up fine and hard salt; so that they give proofs of there being rocks of salt in many places. All along the river Weever, on each side, the earth affords *brine* wherever it is opened: but all these are not fit for boiling, many of the *pits* affording a *brine* too weak to be worked to any advantage. The very strongest *pits* sometimes also become at once too weak; this is owing to the irruption of fresh springs into them, and sometimes the river itself makes its way into them, and overflows them with such a quantity of fresh water, that they are utterly spoiled. The *brine-pits* at Weston near Stafford, afford a *brine* that stinks like rotten eggs; this turns instantly to ink with galls, and purges and vomits violently, if taken even in a small quantity. This in boiling deposits a white flaky sand, or stony matter, without smell or taste, and the salt is pure and fine.

The *pit* at Droitwich in Worcestershire, affords no sand in the boiling, nor any the least sediment of the stony matter at the bottom of the pan, and the salt is the purest of all the others: and by the people of the country it is esteemed the most wholesome; because of its being without the sand. This and the other *pits* hereabout, all have the smell of rotten eggs, especially after a little rest, as on the Monday morning after the Sunday's rest. If meat be put to pickle in the brine of these *pits*, instead of being preserved it will stink in twenty-four hours, sometimes in twelve, yet they yield the best salt of any inland *pits* in the world.

The sulphur spaws of Yorkshire, which are very numerous in different parts of the county, all stink violently of rotten eggs; but if well drawn and worked, they would prove as inoffensive as the rest, and only so many weaker or stronger brine *pits*; and the smell is no other than that of the Cheshire and Staffordshire brine, when it has been left some time at rest. It is remarkable, that tho' the stony matter is deposited in such vast plenty by the waters of all our salt springs, it is not found in any abundance in those places where salt is made out of sea sand, as in Lancashire and some other places; so that it is much more than the natural quantity of spar contained in water that is thus deposited; and indeed it appears from trial, that the brine of our salt springs, in general, contains more than twenty times the quantity of spar that common water does.

This stony matter separates itself from the water before the salt does, and thus it appears in many other waters impregnated with mineral particles. The vitriolic waters all contain ochre and salt, and in all these the ochre separates itself first in the boiling, and then the vitriol; and the stony matter precipitated from common salt springs affords, on an analysis, the salt called *nitrum calcarium*, in considerable abundance. Phil. Trans. N° 156.

PIT-*fish*, or PIT-*visch*, in zoology, the Dutch name of an East Indian fish, approaching very much to the nature of the European turdus, but that it has no scales. Its body is not flat but rounded, and is variegated with blue and yellow spots; its eyes stand very prominent, and the fish is able, at pleasure, to thrust them out or draw them in; its back-fin is prickly. It loves muddy and foul places, yet is a very well-tasted fish. *Ray*'s Ichthyogr. Append. p. 6.

PITANGUAGUACU, in zoology, the name of a Brasilian bird of the starling kind, called by the Portuguese there the *bemetre*. It is of the size of the common starling; its beak is long, thick, and of a pyramidal figure; its head broad and flatted; its neck short, which as it sits it contracts also, so as to make it appear much shorter; its legs and feet are of a dusky brown; it has a very loud and shrill voice; its head, neck, back, wings, and tail, are all of a brownish black, with a faint admixture of green; the lower part of the throat, the breast, and the belly, are yellow, the upper part of the throat white; its beak is very sharp-pointed. *Marggrave*'s Hist. of Brasil.

PITCH (*Cycl.*)—The antients had a peculiar kind of *pitch* called *brutia*, which was inspissated to a higher than ordinary degree for certain uses; such as the receiving a proper quantity of bees wax, to render it the zopissa used in coating the bottoms of ships; which the common *pitch* could not do, being of too soft a consistence for this use. Pliny tells us, that it was made in this manner: The wood was cleaved and formed into a pile, with proper trenches cut in the earth to receive what run from it in burning. When the pile was lighted, the first thing that flowed into these trenches was a thin fluid liquor like water. This, he says, was called *cedrium* in Syria, and was used in Egypt in the preserving dead bodies. The next liquor that ran out from the pile, he says, was thicker, and was *pitch*; and that a part of this was afterwards boiled in brass vessels, with an admixture of vinegar, and then became very solid and hard, and was called by this name of *brutia*.

However right this author may be in his account of the *brutia*, it is evident that he errs in making the first runnings of the wood the *cedrium*; for this was peculiarly the name of the tar of the cedar; and as there are plenty of turpentine trees in Syria, and the *pitch* and tar of that country were always made of those trees, it is very improper to give the name *cedrium* to it: no one ever called the turpentine and cedar by the same name; nor is there any reason why their products should be thus confounded. Vitruvius is very express in ascertaining the sense of the word *cedria* to the produce of the cedar; he says, that the cypress and pine yield their several fat juices or resins, and that the cedar in like manner yields its oil; which is thence called *cedrium*, or *cedria*, and has so much of the peculiar virtues of the wood, that it preserved books and other things, on which it was rubbed, from being eaten by worms.

This author, however, tho' he distinguishes the product of the cedar from that of the cypress and pine, yet he confounds together the two substances, called by the Greeks *cedrium* and *cedrelæum*. The *cedrium* was properly the *pitch* of the cedar; this was the hard substance produced by burning the wood; but the thin liquid substance called *cedrelæum*, which was the only thing that could be used for rubbing over books, *&c.* was an oil separated from this *cedrium*, or *pitch* of the cedar by melting.

PITCH *of Castro*, in the materia medica, the name given by Boccone and some other writers, to a thick kind of bitumen found issuing out of the cracks of some rocks near the village of Castro; from whence it has its name: it is famous in the ecclesiastical state for its medicinal virtues. *Boccone* Mus. de Fisci.

PITCH is also used by architects and builders, for the angle which a gable-end, and consequently the whole roof of a building is set to. If the length of each rafter be ¾ of the breadth of the building, then they say that roof is of a *true pitch*; but if the rafters are longer, they say 'tis a *high* or *sharp-pitched roof*; if shorter, they call it a *low* or *flat-pitched roof*.

PITCHED, in the sea language. They say the mast is *pitched*, when it is put or let down into the step; also the mast is *pitched* too far aft, when placed too near the stern.

PITH, (*Cycl.*) in vegetation, the soft spungy substance contained in the central part of plants and trees. As the substance of the trunk in trees become more woody, the *pith* is compressed and straitened to such a degree, that it wholly disappears.

It is plain from this, that the office of the *pith* in vegetation cannot be very great, since it is not of perpetual duration. By its spungy structure, it seems fitted to receive any superfluous moisture that might transude thro' the pores of the woody fibres. If by the excess of such moisture, or from any other cause, it happens to rot and perish, as frequently happens in elms, the tree is found to grow fully as well without it; a proof it is of no essential use in vegetation. *Boerhaave*'s Chem. p. 139.

The *pith* of trees is continued farther into their minute parts than is generally conceived; the smallest branches and pedicles of the leaves and flowers have their share of it, according to the nature of the tree they belong to; and even the middle ribs of the leaves, when examined by the microscope, are not without it: a transverse section of one of these ribs of the leaf of a *pithy* tree, shews a very beautiful arrangement of vessels, or little bladders, containing a quantity of clear liquor, and resembling in all respects those of which the *pith* in the branches is composed. The *pith* in these is not round, however, as in the others, but flat, and runs from one end of the pedicle to the other, in form of a thin white rib, gradually lessening to a point.

The *pith* of plants, in fine, seems what the marrow is in animals, a congeries of an infinite number of vesicles, which seem

feem deftined to feparate a finer juice than is neceffary for the nourifhment of the coarfer parts of the tree. It is obferved of plants which have a larger than ordinary fhare of *pith*, that they produce larger quantities of flowers than others; inftances of this are feen in the rofe, the lilac, and the common elder: and in the ferulaceous plants, the quantity of flowers is not only profufely large, according to the great quantity of *pith* in their ftalks, but the *pith* feems carried up the ftalks all the way to the feeds themfelves; the long feeds of the fweet myrrhis, and other the like plants, while not ripe, being only *pith*. Mem. Acad Scienc. 1709.

PITHECALOPEX, the *femivulpa*, or *ape-fox*, a name given by Aldrovandus and fome others, to that ftrange American animal which we call the *opoffum*.

The name is compounded of that of the *fox* and the *ape*; of the natures of both which animals it is fuppofed by fome to participate. See the article OPOSSUM.

PITHIAS, or PITHITES, with fome writers, a fort of comet, or rather meteor, in form of a tub. Of thefe it is faid there are divers kinds, *viz.* fome of an oval figure, others like a tun or barrel fet perpendicular, and fome like one inclined, or cut fhort off; others having a hairy train or bufh, &c.

PITHYUSA, in botany, a name ufed by many authors for a fmall fpecies of fpurge. See the article TITHYMALUS.

PITUINA, in the materia medica, a name for the refin of the pitch-tree.

PITYIDES, a name ufed by fome authors for the kernels inclofed in the cones of the fir or pitch-tree; they are recommended by the old phyficians, in diforders of the breaft.

PITYLISMA, a name of one of the exercifes prefcribed by the antient phyficians, as of great fervice in chronic cafes. It confifted in a perfon's walking on tip-toe, and ftretching his hands as high above his head as he could, keeping the whole body alfo as much upon the ftretch as might be. In this condition the patient was to walk as far as he was well able, all the while moving about both hands as much as he could, in all directions.

PITYRIASIS, a name given by the antients to a fcurfy diforder of the head and eye-brows, and of any other part where there is hair. It makes the fkin feem as if covered with bran, and is attended with a troublefome itching.

PIVA, in the Italian mufic, a hautboy, or a cornet. See the articles HAUTBOY and CORNET, *Cycl.*

PLACAGNODIAUGIA, in natural hiftory, the name of a genus of fpars.

The word is derived from the Greek πλαξ, a cruft, ἁγνὸς, pure, and διαυγὴς, pellucid.

The bodies of this genus are cryftalline terrene fpars, or fparry bodies with much of the brightnefs and tranfparence of cryftal, but debafed by an admixture of earthy matter, and are imperfectly pellucid, and formed into thin plates with flat furfaces, but covered at times either in part or entirely, with tubercles or botryoide prominences, and are compofed of arrangements of oblong concretions, of no determinately angular figure.

Of this genus there are only two known fpecies, tho' thefe vary fo much at times in figure, that they might lead an inaccurate obferver into imagining there were many diftinct fpecies of each. 1. A hard femi-pellucid and yellowifh brown one. This is found in many parts of England; in fome places encrufting over the fides of fiffures of ftone, and in others coating over vegetable bodies in fprings, &c. 2. A brittle pellucid and whitifh one, found on the fides and tops of our fubterranean caverns on Mendip hills and elfewhere, and in form of a roundifh ball, feemingly compofed of threads, in the neighbourhood of Efperie in Hungary. *Hill's* Hift. of Foff p. 342.

PLACAGNOSCIERIA, in natural hiftory, the name of a genus of fpars.

The word is derived from the Greek πλαξ, a cruft, ἁγνὸς, pure, and σκιερὸς, opake.

The bodies of this genus are dull and opake cryftalline terrene fpars, formed into crufts, and of an irregular and not ftriated texture within.

Of this genus there are three known fpecies: 1. A hard whitifh brown one, found very frequently on the roofs and fides of caverns on Mendip hills, and in other parts of England. 2. A dull crumbly whitifh one, found in many parts of England, encrufting the fides of caverns, and of fiffures of ftone. And 3. A dull pale brown friable one, of a very coarfe texture. This is the moft common of all the bodies of this genus, and is found in variety of forms, among others encrufting the fides and bottoms of our tea-kettles, and other veffels, in which water is frequently boiled. *Hill's* Hift. of Foff. p. 346.

PLACE (*Cycl.*)—*Place* is ufed in the doctrine of artificial memory: and thefe *places* may be either fuch in a proper fenfe, as a door, a window, a corner, &c. or familiar and known perfons; or any other thing at pleafure, providing they be placed in a certain order, animals, plants, words, letters, characters, hiftorical perfonages, &c. tho' fome of thefe are more and fome lefs fit for the purpofe; but fuch kind of *places* greatly help the memory, and raife it far above its natural powers. *Bacon's* Works Abr. Vol. II. p. 474, 475. See the article MEMORY, *Cycl.* and *Suppl.*

PLACE-*bricks*. See making of BRICK.

PLACENTA (*Cycl.*)—The *placenta* has generally been looked upon as an original part among the fecundines; but according to Dr. Thomas Simfon of St. Andrews, it feems to have no place in the ovarium, nor in the uterus, till once the ovum becomes contiguous to the fundus, and then every contiguous part becomes really a *placenta*. He thinks the fundus uteri, a place peculiarly fitted for the growth of the *placenta*, as proper foils encourage the growth of the roots of trees and fhurbs, many of which are propagated by the branches however placed; fo that every part of them feems equally fitted to be root or branch. Hence he thinks extra uterine conceptions can have no *placenta*; and he fays, there are no inftances in authors to contradict his opinion. See Med. Eff. Edinb. Vol. IV. Art. 13.

The *placenta* does not increafe in the fame proportion which the fœtus does: for the fmaller the fœtus is, the *placenta* is proportionally larger. *Monro*, in Med. Eff. Edinb. p. 145. from *Ruyfch*.

The *placenta* generally adheres to, or near the fundus of the womb, and is covered on the fide next to the womb, with a fine membranous continuation of the chorion. Vid. *Monro*, Medic Eff. Edinb. Vol. II. p. 128. and the authorities there quoted.

The feparation of the *placenta* from the womb muft produce abortions, and this may be occafioned by different caufes operating in various manners, and requires very different treatment to prevent the lofs of the fœtus. See *Monro*, in Med. Eff. Edinb. Vol II. Art. 11. or it's Abridgment, Vol. I. p. 338, feq.

PLACENTA, in botany, a term improperly given by Mr. Houfton, in the Philofophical Tranfactions, N° 421, to what is ufually called *receptacle*. See RECEPTACULUM *feminum*.

PLACENTA, in natural hiftory, the name of one of the claffes of the echini marini. The characters of thefe are, that they are of a depreffed or flatted form, and are wrought in various fhapes, as the paftry people make their cakes; they all have a cinquefoil flower at their top, and their mouth is in the middle of the bafe; the aperture for their anus is ufually near the edge. See Tab. 8. N° 9, 10.

Of this clafs there are three genera: 1. The *mellita*. 2. The *laganum*. And 3. The *rotula*. Which fee under their feveral heads. *Klein's* Hift. Echin. p. 30.

PLACENTA, among the antients, a kind of cheefe-cake, the moft fimple kind of which was made of flower mixed with oil and cheefe, to which honey was added: but the more luxurious fort of people added likewife a great variety of herbs and fruits, as alfo fugar, eggs, butter, &c. *Pitifc.* Lex. Antiq. in voc.

PLAGIAULOS, πλαγιαυλος, among the antients, a kind of flute.

PLAGIOPLATEUS, in natural hiftory, a term ufed by Artedi and others to fignify depreffed, in oppofition to the term *cathetoplateus*, which fignifies compreffed. See both explained under the article CATHETOPLATEUS.

PLAGIURI, in natural hiftory, the name of one of the great claffes, or families of fifhes. The characters of which are, that the tail is placed horizontally. They refpire by means of lungs, and have ufually a double fiftule in the head. They are viviparous, and the males have a penis and teftes, the females the vulva, ovaria, mammæ, &c. and they bring up their young with milk.

The term is derived from the Greek πλαγίος, tranfverfe, and οὐρὰ, a tail. Vid. *Artedi*, Gen. Pifc. *Linnæi* Syftema Naturæ, p. 31.

PLAGUE (*Cycl.*)—Dr. Dover fays he cured the *plague* among fome failors, in a voyage, by one very plentiful bleeding to the quantity of an hundred ounces, and with drink fharpened with fpirit and oil of vitriol. Med. Eff. Edinb.

PLAIN (*Cycl.*)—PLAIN *furface*, in geometry, that which lies evenly between its bounding lines; and as a right line is the fhorteft extenfion from one point to another, fo a *plain furface* is the fhorteft extenfion from one line to another.

PLAISE, in ichthyology, the Englifh name for the fifh called by authors *plateffa* and *paffer lævis*, by fome *quadratulus*.

It is, according to the Artedian fyftem, a fpecies of the pleuronectes, and is diftinguifhed by that author by the name of the *pleuronectes* with fmooth fides, and with a fpine near the anus, and the eyes and fix tubercles placed on the right fide of the head. This name carries a diftinctive character with it; and it were to be wifhed that we had fuch names in common ufe among authors for all the fifh that are known to us. See PLEURONECTES.

PLAN (*Cycl.*)—PLAN *of a baftion*, in the military art, is the fame with the face of a *baftion*. See FACE.

PLANE-*tree*, *platanus*, in botany, the name of a genus of trees, the characters of which are thefe: The flower is of the amentaceous kind, and is of a glomerated fhape, and compofed of a great number of ftamina with their apices. Thefe flowers are barren, and the embryo fruits are found on other parts of the plant; thefe finally become larger, and contain feveral feeds winged with down.

The

The species of *platanus*, enumerated by Mr. Tournefort, are these: 1. The true oriental *platanus*. 2. The occidental or Virginian *platanus*. *Tourn.* Inst. p. 590.

PLANKS, in a ship, are the timbers which go fore and aft on each side of the ship, whereon lie the beams of the first orlop.

Garboard PLANK, in a ship. See GARBOARD.

PLANT (*Cycl.*)—The greater the degree of heat given to *plants* to a certain degree in the natural way, the sooner they go through the whole business of their fructification. In the northern regions, where there are but a few summer months, the herbs all are ripened in them in a surprizing manner: in Lapland, for instance, where the greater part of the year is subject to intense and inceffant frosts, and for a considerable time to the entire absence of the sun, the summer season affords an excessive heat for two months, the sun never setting in all that time. This season comes on toward the latter end of June, and the grass and other herbs then first begin to appear in their young shoots above the ground, and the trees bud; but all vegetation is, after this, carried on with such speed, that in a fortnight the flowers of the herbs and trees are expanded, and the leaves of their full size and maturity. *Scheffer's* Hist. Lapon.

The virtues of *plants* are very variable; a change of climate will alter or destroy them, as we see in many of the medicinal *plants* of other countries, brought over hither, which, tho' they seem to flourish with us, never possess their virtues in the same degreee as in their native climate. The bodies of different animals also render the effect of the same *plant* different: the tithymals or spurges are all of them very violent cathartics, when taken by us; but yet they are eaten by goats and several other animals without hurt, or without any purgative effect, and seem to give them a particular share of vigour and spirits. The fish are, on the other hand, more strongly affected by it than we are; for the juice made into paste with flower and honey, poisons, or at least intoxicates them so, that they may be taken out of the water with one's hand. Bitter almonds are of no ill consequence to us, yet they kill all sorts of birds. *Deslande's* Trait. Physiq.

Imperfect PLANTS, in botany, a name given to those *plants* which seem to want both flower and seed. These were once a very large tribe of *plants*, but the more accurate observations of the moderns have proved, that the most of these *plants* really contained seeds, and those very numerous, tho' so small as not to appear obvious to the naked eye: and probably the farther discoveries of the microscope will in time leave us no one *plant* deserving the appellation of *imperfect*. In Mr. Ray's time, many whole genera of *plants* were esteemed imperfect; but he includes the several kinds he calls so, under three general heads: 1. The submarine. 2. The fungufes. And, 3. The mosses. Tho' many of all these kinds have by later authors been shewn to have true seeds, and it is scarce to be doubted of the rest. *Ray's* Synopf. Stirp. Brit. p. 1.

Flowering of PLANTS. See the article FLOWERING.

Analysis of PLANTS. The common method of attempting the *analysis of plants*, by common distillations, gave hopes that it would prove very useful in determining their virtues; but experiment shewed it to fail of this intent, since the wholesome *plants* and the poisonous ones afforded by this means much the same sort of principles; and on the whole, these appeared in a great measure to be creatures of the fire rather than parts of the subject. This set Mr. Boulduc of the Paris academy upon trying, whether there might not be some way invented at once more simple and more certain; and with this view he attempted to examine the juices and decoctions of several *plants*, to find their essential salts, which had not been procured in their natural state by the chemical trials. The *plant* this gentleman chose as the subject of his experiments in this view, was the common borage.

First, he made a large quantity of a decoction of borage; this he divided into three equal parts: the first of these he evaporated to a pellicle, or to the consistence of a syrup; it was then of a blackish colour, and was charged with a great quantity of oily particles. This being set by for some days in a warm time of the year, covered itself with a thick skin, which was again covered by a mouldiness. When this skin was removed, there appeared underneath a large quantity of chrystals, in fine slender filaments like needles, mixed among a large quantity of other crystals, which were small, and of no regular figures; all these were swimming in a liquor of the thickness of a syrup. These long crystals being taken out of the liquor, and laid upon a hot iron, took fire, and flamed in the manner of salt-petre when mixed with any sulphureous substance; and, in truth, this was a salt-petre, yet loaded with the oily matter of the decoction.

Here, therefore, is a clear proof, not only of the nitrous acid being in this plant, but of plain nitre itself; for, on pouring oil of tartar on a solution of this salt, there was no precipitation made of any substance whatever; which would have been the case, had there been in this state any earthy matter for its basis.

The second portion of this decoction was divested of its oil by means of lime, and then evaporated to a light pellicle over a very gentle heat. This was set by to rest for some days, and finer and more perfect crystals were found, shot in the form of needles in it: these were truly nitrous, and occupied the upper part of the liquor; below these there were a great number of other cubic ones, which were easily known to be crystals of sea salt.

The long crystals of this operation took fire on a lighted charcoal, and appeared plain nitre; and the others, when dry, crepitated in the fire exactly in the manner of sea salt: and when a solution of them was poured upon a solution of silver, made in spirit of nitre, it immediately occasioned a white curd to appear, which being separated, washed, and put to the fire, became a true luna cornea, being transparent and easily cut with a knife. Here, therefore, are plain proofs of nitre and sea salt in this *plant*. Mem. Acad. Scienc. Par. 1734.

The third portion of the decoction was poured upon some fresh wood ashes, and being afterwards evaporated to a pellicle, and set by for some days, there was found in this more nitre than in any of the others; and that whiter and more clear, the others being usually coloured brownish or reddish by the decoction. The occasion of this seems to be, that part of the nitrous acid, which in the other experiments neither joined with any earthy matter, nor with the fatty matter of the decoction, mixed with the salts of the lixivium, made by pouring the liquor which contained it on wood ashes, and thus yielded a much larger quantity of saltpetre than before.

The fatty substance which covered the first decoction being dried, was found to contain a great quantity of nitre, which it had not suffered to shoot, or form itself into crystals: this dried crust being laid on a burning charcoal, took fire in the same manner as if nitre and powder of charcoal had been thrown into a crucible made red hot.

The salts of the *plant* being thus obtained from its decoction, it was determined to try whether the *plant* remaining after the decoction had any more to yield. To try this, it was gently dried in a shade, and burned in a covered vessel to a black coal, and afterwards, in an open fire, to ashes.

Of these ashes there was made a lixivium in the common way, in order to be evaporated for the salt: this lixivium being mixed with syrup of violets, scarce at all altered it from its blue colours, only just bringing on a faint greenishness, which soon went off again, and left the syrup of as fine a blue as before; this made it evident, either that there was very little alkali salt there, or else that it was blended with salts of some other kind, which altered its effects: and this proved to be the true state of the matter on farther experiment, for, evaporating the lixivium to a pellicle, there very soon shot in it regular and beautiful crystals of a salt, having all the characters of tartarum vitriolatum. A second evaporation of the lixivium afforded more of the same salt, but in smaller crystals. Evaporating the liquor to about half its quantity, and setting it again to shoot, there appeared plain cubic crystals of sea salt; which being strictly examined, were found to be perfect sea salt, no way altered, but having stood the force of the calcination.

After these salts had been separated from the lixivium, it changed syrup of violets immediately to a beautiful green, which colour it always retained.

It is evident from these experiments, that this *plant* affords four different kinds of salts, *viz.* nitre, sea salt, tartarum vitriolatum, and the common fixed alkali; and it is hence no trivial observation, that the three mineral acids are found here all in one *plant*. It is not to be supposed, indeed, that the tartarum vitriolatum was actually in the *plant* in that form, but it is very evident, that the vitriolic acid did always exist there, ready to form it; but that being, before the calcination, enveloped in the oily matter of the *plant*, it was not easy to discover it either by its properties or effects: but as soon as the oil was dissipated by fire in the calcination, the vitriolic acid immediately became free, and finding the alcaline salt of the *plant*, or its fixed nitre, which had remained after the deflagration, it immediately united with it, and formed a tartarum vitriolatum in the same manner as a tartarum vitriolatum may be made from salt of tartar and common sulphur, after the oily or inflammable part of the sulphur is burnt away.

It is not only this *plant* that yields a vitriolated tartar from a lixivium with its ashes, but great numbers of others of the aromatic and bitter kinds: whence it appears, that the vitriolic acid, tho' the most fixed of all the mineral acids, yet raises itself into the juices of a great number of *plants*; and on the result of great numbers of experiments, it appears, that there are very few *plants* which yield a pure alkaline salt, perhaps salt of tartar is the only perfectly pure known alkali of this kind, which retains no portion of any other salt.

Ashes of PLANTS. The ashes of a *plant* carefully prepared, retains its exact form till disturbed by accidents. The way of preparing them is this: Take a whole *plant* which has been used for the distillation of the oil, water, &c. lay it evenly upon a flat plate of iron, and place this on a clear fire, that no smoak may prevent the success of the operation; continue and raise the fire, till the whole substance of the *plant* appears perfectly ignited. There first arises a light smoak from it, this gradually becomes darker, and at length as black as pitch; the smell of burning increases as the smoak increases, at length the smoak breaks out into flame, and then the smell in a great mea-

measure ceases: the *plant* by degrees grows black, as the smoak arises, and as soon as perfectly black all over, it takes fire. When the flame ceases, the leaves appear white; but if any black spots remain, there are always seen sparks of fire scattering themselves about on them, till the blacknefs is perfectly consumed. The ashes being now become perfectly white, yield no smell nor the least appearance of fire; and they yet retain, after all this violence of fire, the perfect form of the *plant*, even to a microscopic observation: for, if examined by glasses, there will be found every feature and lineament of the *plant*, even the hairinefs of the stalks, or down upon the leaves; every rising and cavity natural to the plant, appear also distinct, and every the smallest fibre. But this only remains while they are unmoved, the moment they are disturbed, tho' but by breathing upon them, the whole falls to dust, and the form is irrecoverably lost.

The ashes thus carefully prepared, are perfectly insipid and scentless, and when lixiviated in the common way for making the fixed salt, afford no salt at all; but only on the evaporation leave a small quantity of a matter resembling lime: the remaining ashes are wholly terrestrial, and serve excellently for the making copels, for the use of assaying. *Boerhaave's* Chem. P. 2. p. 19.

From this we learn, that the *plant*, by having been previously boiled in water in the distillation, was divested of all its salts; and that in general, water, with a great degree of heat, is capable of extracting from any vegetable all its saline particles, whether volatile or fixed. We find, however, that water can never separate the fixed oil, which here shews itself to have wholly remained in the *plant*, by the smoak, smell, and flame it yields; and by the sparks of fire in the remaining black parts of the *plant*, which were wholly owing to the remains of this oil, no fire being able to make the smallest spark afterwards appear in the ashes.

Air, as well as fire, is necessary to this oil's taking flame; for in a covered vessel it will not blaze till the cover is taken off. This thick oil is extremely different from what we call the essential oil of a *plant*, and seems to be the same in all vegetables; and to this they owe their cohesion: while the essential oil and salt are extracted from the *plant* by boiling, it yet holds together in its native figure and strength; but as soon as the black oil is dissipated by burning, the whole firmnefs of the *plant* is lost, and a breath of air blasts it to dust.

Salts of PLANTS. It has been observed by all who have examined the different essential *salts of plants*, that some of them, when thrown on the fire, have the effects of salt-petre, and others of common sea-salt; and it has been concluded from hence, that they really contained particles of those salts which their roots had taken in with their nourishment, and conveyed up into the stalk and leaves with the juices; and that these salts still retained their original nature, and were no otherwise altered than by the mixture with other substances in the plant. But as two plants of different qualities, when set in the same earth closely by one another, shall out of the same juices make a medicine, a sallad, or a poison; it cannot be, but that the substances absorbed by the root, be they what they will, must be greatly altered in the plant; insomuch, that a salt purely nitrous, when received into the root, might become of the nature of sea salt, or of the volatile urinous kind, according to the different organs of the plants, and the different natural fermentations it might meet with there. To be perfectly informed of this, Mr. Homberg made the following experiment:

He took a large quantity of rich black garden mould, and washed it in several waters, to carry off all the salts it might contain: this done, he divided the earth into four boxes or cases of wood, into each of which there was put about two hundred weight. Two of these cases of earth he watered with a solution of salt-petre, so as to make each imbibe about two ounces of that salt; the other two cases were left with the earth insipid as the washing had made it, and care taken to water them with none but perfectly pure water, so that they might remain as simple as possible. In one of the cases of nitrous earth, and in one of those of simple earth, he sowed fennel; and in the other two, garden cresses.

The herbs in all the cases grew very well, and when they were grown to about eight inches high, they were all gathered; and when the roots were cleansed, and the whole product weighed, those plants which had grown on the simple earth weighed twenty-five ounces, and those in the nitrous earth twenty-six; their smell and taste manifested no sort of difference in either. In order to examine these plants, while yet quite fresh, by means of fire, he put a pound and an half of each, with their roots, into a retort of glass; he placed these retorts first in a balneum mariæ, and then in a sand-heat, in order to drive over all the aqueous humidity. The quantity of water from each retort was within a few grains of the same weight; and from the beginning to the end of the distillation, there was not the least appearance of any acid.

After this, the cresses which had grown in the insipid earth, yielded a drachm of volatile salt; and that which had grown in the earth which had imbibed salt-petre, yielded seventy-five grains.

The oil of each was very nearly the same in quantity; that from the plants in the salt-petre earth weighing six grains more than that of the plants of the insipid earth.

The lixivial salt was two drachms from the plants in the nitrous earth, and one drachm and sixty-seven grains from those in the insipid.

The differences between those two parcels of plants upon the analysis, appeared on the whole so little, that it could not be counted any thing; since the more or less close luting of the vessels, or many other accidents in the distillation, might have easily occasioned as much in plants perfectly the same in all respects. If there be any thing, however, to be collected from the experiment, it is, that the earth moistened with a solution of nitre, yielded more of the principles than the other; probably from its actually affording a quantity of salt to the juices of the plant in the growth: but as the nitrous earth afforded a plant which yielded more oil than that from an insipid soil, it must be from this that the lotions of the earth not being able to carry off any of the fatty parts, they remained in the same quantity in both; but that the nitre, where it was, had contributed somewhat to the breaking of them, and the rendering them more fit to be absorbed by the plants. From the different weights of the plants when gathered, after the same time of growth, from the same seed, and with all the same advantages in common, proves, that the nitrous salts in the earth are not essentially necessary to vegetation, since the *plants* in the insipid earth grew very well without them; yet that they are very useful, since the *plants* produced there were of a greater bulk, and according to the whole analysis, if the differences are to be depended on as resulting wholly from the nature of the subjects, they yielded more of all the active principles; and therefore, that they were to all purposes better *plants*.

The fennel in these boxes was not gathered with the cresses, but left till it began to bud for flowering: at this time there was found a very great difference, both in the size and appearance of the *plants* of the two sorts of earth. That in the insipid earth was lank, weak, and of a yellowish green; and being gathered, weighed only nineteen ounces: whereas the fennel growing on the nitrous earth seemed in a very vigorous state, its leaves were of a dark green, and it weighed full two pounds. Mr. Homberg weighed nineteen ounces of each of the *plants* fresh, and with their roots, to make the analysis of them in the same manner as he had before done that of the cresses. In the first distillation the water began to taste acid in the first drops, and continued to increase in acidity as long as it ran; and the insipid earth left by the fennel which grew in the nitrous earth, was an ounce more in weight than the residuum of the *plant* which had grown in the insipid soil. That of the nitrous earth yielded one drachm and twelve grains of oil; that in the insipid, only sixty-three grains: neither one nor the other yielded any volatile salt, only the last ounce of the aqueous liquor made some little effervescence. The first salt was in the quantity of three drachms from he fennel of the nitrous earth, and two drachms and ten grains from the insipid earth.

The *plants* had appeared above ground in the same time from their seeds in the nitrous and in the insipid earth, and grew equally vigorous and well for a month; but after that time, tho' both were watered in the same manner, and the same care in all respects was taken of them, the *plant* on the insipid earth became languid, and that on the nitrous earth continued to grow vigorously and well.

It seems that in the first stages of the growth of the *plants*, the two lobes of the seed furnished a proper nourishment to the stalk and leaves, and required no more than mere water, a pure simple fluid to divide its parts and carry it up from the root; but that when these lobes were wholly consumed, and the *plant* was to find its whole nourishment in the earth, there an earth rendered insipid by the carefully washing away all its salts, could not supply a proper and sufficient nourishment, but that an earth, after it had been made to imbibe a certain portion of nitre could: whence the fennel in the insipid earth could not continue to grow vigorously, after the lobes of the seed were destroyed, tho' that in the earth impregnated with an adventitious salt could.

It is true, indeed, that the *plant* in the insipid earth did not entirely perish, and it is reasonable to conclude thence, that all the washing we can give with hot water cannot divest earth of all its salts, but only of those which are most easily soluble; whence it takes away not all, but only the principal fund of nutrition. All the washings in the world must also leave earth impregnated with all the fatty particles it ever had, and these are very instrumental to the growth of *plants*; but these, without some salts, cease to be of their proper use, since they cannot be broken or divided into parts small enough to enter

the vessels of *plant*, otherwise than by these salts. Mem Acad. Par. 1693.

It is very observable, in the course of these experiments, that the cress, tho' planted in an earth containing salt petre, which is well known to be an acid salt, yet yielded, on the analysis, alcaline principles, and not the least mark of an acid in any part of the processes, and this just in the same manner as if it had grown upon an earth impregnated with dung; and that the fennel, whether growing on the nitrous earth, or on the insipid, afforded a large quantity of acid in all its principles, not excepting even its fixed salt, which was very little of the alkali; and by the mixture of the acid of the plant was converted almost into the nature of a neutral salt. Hence it appears that a salt, tho' acid in itself when absorbed into the vessels of an alkaline *plant*, such as the cress, ceases to be any longer an acid; and that a *plant* naturally acid, whether it grow in an earth impregnated with an acid salt, or wholly divested of salts, yet it retains its acid nature, and gives proof of it in all its principles on an analysis; whence it is very reasonable to conclude, that the salts found in *plants* are made what they are in those *plants*; and that the salts of the earth, in which the *plant* grows, be they of what nature they will, will change that nature in the vessels of the *plant*, according to the diversity of its organs, and of the different fermentations they undergo in the course of their alteration there.

The weights above mentioned are French, the word *gros* being translated drachm, tho' really exceeding it by twelve grains. See WEIGHT, *Cycl.*

Tracheæ of PLANTS See the article TRACHEÆ *of plants.*

Transportation of PLANTS. See TRANSPORTATION *of plants.*

PLANTS *in Amber* The cabinets of the curious afford numerous instances of small animals, such as flies, beetles, and the like, buried in *amber*; but the parts of *plants* are more rarely found thus preserved; yet we are not without instances that the same accident may happen to them. The learned Hartman mentions a piece of *amber* in his own possession, in which there were preserved some leaves of the common alga, and another in which a seed of the common lime-tree, with part of its pedicle, and others in which the capsule with its seeds and pedicle were preserved; the pedicle standing out at the end of the piece of *amber*.

Some have given accounts of whole pinnated leaves of *plants* thus preserved, and the mosses are so common, that there is no doubt of the reality of their being naturally buried there. They are generally found only in single leaves and small fragments, but sometimes in whole branches; in which case *amber* can shew no greater beauty. Pieces of straws, sticks, and the barks of trees are often found in it also; but the greater part of these, when strictly examined, are found to be fragments of fossile wood, or of the matter called by Hartman the *matrix* of *amber*; which is a fibrose substance, and much of the appearance of wood, but is really only a bituminous earth. These all must have been received into the *amber* in the same manner that the insects were; that is, while the *amber* was yet moist or soft. These things falling into its way might bury themselves in it, and then must be preserved in it in the hardened state. See SUCCINUM.

Fossile PLANTS. Many species of tender and herbaceous *plants* are found at this day, in great abundance, buried at considerable depths in the earth, and converted, as it were, into the nature of the matter they lie among; fossile wood is often found very little altered, and often impregnated with substances of almost all the different fossile kinds, and lodged in all the several strata, sometimes firmly embedded in hard matter, sometimes loose: but this is by no means the case with the tenderer and more delicate subjects of the vegetable world. These are usually immersed either in a blackish slaty substance, found lying over the strata of coal, or else in loose nodules of ferruginous matter of a pebble-like form, and they are always altered into the nature of the substance they lie among; what we meet with of these are principally of the fern kind; and what is very singular, tho' a very certain truth, is, that these are principally the ferns of American growth, not those of our own climate.

The most frequent *fossile plants* are the polypody, spleenwort, osmund, trichomanes, and the several larger and smaller ferns; but beside these there are also found pieces of the equisetums, or horse-tails, and joints of the stellated *plants*, as the clivers, madder, and the like; and these have been too often mistaken for flowers; sometimes there are also found compleat grasses, or parts of them, as also reeds and other water *plants*; sometimes the ears of corn, and not unfrequently the twigs or bark, and impressions of the bark, and fruit of the pine or fir kind, which have been, from their scaly appearance, mistaken for the skins of fishes; and sometimes, but that very rarely, we meet with mosses and sea-*plants*.

Many of the ferns not unfrequently found, are of very singular kinds, and some species yet unknown to us; and the leaves of some appear set at regular distances, with round protuberances and cavities. The stones which contain these plants split readily, and are often found to contain, on one side, the impression of the plant; and on the other the prominent plant itself: and beside all that have been mentioned, there have been frequently supposed to be found with us ears of common wheat, and of the maiz or Indian corn; the first being in reality no other than the common endmost branches of the firs, and the other the thicker boughs of various species of that and of the pine kind, with their leaves fallen off; such branches in such a state cannot but afford many irregular tubercles and papillæ, and in some species, such as are more regularly disposed.

These are the kinds most obvious in England; and these are either immersed in the slaty stone which constitutes whole strata, or in flatted nodules, usually of about three inches broad, which readily split into two pieces on being struck. They are most common in Kenton coal-pits, near Newcastle, and the forest of Dean, in Gloucestershire; but are more or less found about almost all our coal-pits, and many of our iron mines. See Tab. of Fossils, Clas. 6.

Tho' these seem the only species of *plants* found with us, yet in Germany there are many others, and those found in different substances. A whitish stone, a little harder than chalk, frequently contains them: they are found also often in a grey slaty stone, of a firmer texture, not unfrequently in a blackish one, and at times in many others: nor are the bodies themselves less various here than the matter in which they are contained: the leaves of trees are found in great abundance, among which those of the willow, poplar, whitethorn, and pear-trees, are the most common; small branches of box, leafs of the olive-tree, and stalks of garden thyme, are also found there; and sometimes ears of the various species of corn, and the larger as well as the smaller mosses in great abundance.

These seem the tender vegetables, or herbaceous *plants*, certainly found thus immersed in hard stone, and buried at great depths in the earth; others of many kinds there are also named by authors, but as in bodies so imperfect, errors are easily fallen into, these seem all that can be ascertained beyond mere conjecture. *Hill's* Hist. of Foss. p. 640.

Ice-PLANT See the article ICE.

PLANT-*root*, a term used by Dr. Grew to express the radicle in seeds: he by this name distinguishes it from what he calls the seminal root; which is a very different substance distributed throughout the parenchyma of the seed, but wholly different from it, and preying upon it as the *plant-root* does upon the earth. *Grew's* Anat. of Plants. See the article SEMINAL-*root*.

PLANTAGINELLA, in botany, a name given by Dillenius to a genus of plants since called by Linnæus *limosella*. *Dillen* See the article LIMOSELLA.

PLANTAGO, *plantain*, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, and is wide, expanded at the opening, and usually divided into four segments; from the bottom of this flower rises a pistil surrounded with stamina of considerable length: the pistil becomes afterwards an oval or conic seed-vessel; which when ripe separates transversely into two pieces, and is divided by an intermediate septum into two cells, filled with oblong seeds.

The species of *plantain*, enumerated by Mr. Tournefort, are these: 1. The smooth broad-leaved *plantain*. 2. The broad-leaved *plantain*, with sinuated leaves. 3. The broad-leaved *plantain*, with blood coloured leaves. 4. The broad-leaved hoary *plantain*. 5. The broad-leaved hoary *plantain*, with a white spike 6. The broad-leaved rose *plantain*, with an expanded flower. 7. The broad-leaved rose *plantain*, with flowers disposed in tufts. 8. The broad-leaved *plantain*, with a bushy panicle. 9. The broad-leaved hoary *plantain*, with various spikes. 10. The smaller broad-leaved smooth *plantain*. 11. The smaller broad-leaved hoary *plantain* 12. The hairy or woolly *plantain*. 13. The great narrow-leaved *plantain*. 14. The small proliferous narrow-leaved *plantain*, with foliaceous tops to the stalks. 15. The common narrow-leaved proliferous *plantain*. 16. The narrow-leaved silvery *plantain*. 17. The narrow-leaved serrated *plantain*. 18. The shrubby narrow-leaved *plantain*. 19. The great broad-leaved hoary *plantain*, with three ribs to each leaf. 20. The lesser narrow-leaved *plantain*. 21. The hairy bulbose rooted *plantain*. 22. The narrow-leaved *plantain*, with tufts like the lagopus. 23. The narrowest-leaved three ribbed *plantain*. 24. The alpine *plantain*, with long, narrow and blackish leaves. 25. The three-ribbed mountain-*plantain*. 26. The narrow-leaved and white Spanish *plantain*. 27. The narrow-leaved white French *plantain*. 28. The great narrow-leaved sea-*plantain*, called by some the sea *coronopus*. 29. The lesser narrow-leaved sea-*plantain*. 30. The smallest sea-*plantain*, with rigid grassy leaves. 31. The greater grassy-leaved *plantain*. 32. The smaller grassy-leaved *plantain*. 33. The smallest narrow leaved *plantain*, with heads like the hare's foot. 34. The one-flowered grassy-leaved marsh-*plantain*. 35. The hairy sea-*plantain* of Portugal, with a very long spike. 36. The hairy sea-*plantain* of Portugal, with a short spike.

These are properly *plantains*; but the large plants commonly called by authors water *plantains*, are species of ranunculus. *Tourn.* Inst. p. 127. See RANUNCULUS.

PLANTAGO, in the Linnæan system of botany, is made the name of a large genus of plants, taking in, beside the several species of *plantains*, usually so called, the psyllium, or fleawort, the coronopus or buckshorn, and the gramen junceum, or rush-grass.

The characters of this genus are these: The cup is an erect very short perianthium, divided into four at the edges, and remaining after the flower is fallen. The flower consists of one petal, in form of a cylindraceo-globose tube, with the limb cut into four parts; the segments being depressed, of an oval figure and pointed; the stamina are four extremely long, erect capillary filaments; the antheræ are oblong, flatted, and lean upon the stamina; the germen of the pistil is of an oval figure; the style is slender, and but of half the length of the stamina; and the stigma is simple; the fruit is an oval capsule, containing two cells, parting horizontally; the seeds are numerous, and oblong. *Linnæi* Genera Plant. p. 46.

PLANTE-*ver*, in natural history, the name of an herb sent over from China, where it is called *hiatsaotonetchom*; that is to say, a plant which at a certain time of the year changes into a worm. The Chinese say, that this is a plant during the summer season; but that in winter its stalk dies, and the root becomes a worm. Mr. Reaumur has well observed, that in the present improved state of natural knowledge, we can give no credit to such marvellous accounts; and of the roots sent over to the Academy at Paris, it appeared, that only a certain part of each was to undergo this change: this, however, if true, was no less a marvel than that the whole should.

Father Parenin, who sent it to France, observes, in his account of it, that it was a very scarce plant even in China; being found only at the palace of Pekin there, where also it was not native, but brought from the mountains of Tibet, and some other places on the confines of the Chinese dominions. This father had never seen the leaves or flowers of the plant, but only its roots, which were in high esteem there, not only because of their miraculous changes, but from there possessing the virtues of the famous ginseng; but with this advantage, that the use of them was not subject to be attended with those hæmorrhages which frequently affected the persons who take large quantities of that famous root. The roots of this *plante-ver* are usually about a quarter of an inch thick, and from an inch to three inches in length; but there are much larger in the places where they grow.

These roots had nothing particular in their figure or appearance; but with these the father sent some of those which were supposed to be changed into worms, concerning which he observed, that nothing could more exactly express a worm or caterpillar; the head, the eyes, the feet, and the mouth, being all plainly distinguishable, as well as the several folds and cuttings in of the body. This account was found to be perfectly true; but the mistake was the want of proper accuracy in the observation; for this body, which was supposed to be the root transformed, had in reality never been any part of the plant, but was found to be really and truly a caterpillar. This was one of the under-ground kind, or at least of those which go into the ground to pass their transformation: of these we have a great many different species in all parts of Europe, and some of them, when they are entering into their nymph state, have a custom of fastening themselves to the roots of plants. Of this kind was the Chinese insect, which when the time of its change approached, always selected the roots of this plant as of a proper size and dimension for its purpose; and gnawing off the end hollowed away the stump, so as to introduce its tail into the cavity; where it remains covered with the bark of the root, which so nicely joins to it, that people who observe it in a slight way cannot but mistake it to be a part of the root, or the remainder of the root, a continuation of its body. The more accurate naturalists will, however, easy distinguish the vegetable fibres, which make up the root from the animal ones of the caterpillar; and to an eye accustomed to such researches, the nice joining of the tail to the remainder of the root will easily discover itself. Mem. Acad. Par. 1720.

PLANTED-*coat*, in the manege. See HAIR, *Cycl.*

PLASHING, a term used by our farmers to express an operation performed at certain times upon their quickset-hedges, in order to assist their growth and continuance. This operation is performed sometimes in October, but more usually in February; and this is by much the better season for it. Suppose a hedge to be of twenty or thirty years growth, and full of old stubs as well as young shoots, this is the kind of hedge that requires *plashing* most of all.

The old stubs must be cut off within two or three inches of the ground, and the best and longest of the middle sized shoots must be left to lay down. Some of the strongest of these must also be left to answer the purpose of stakes. These are to be cut off to the height at which the hedge is intended to be left; and they are to stand at ten foot distance one from another: when there are not proper shoots for these at the due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all but those shoots which are intended to be used either as stakes, or the other work of the *plashing*: the ditch is to be cleaned out with the spade: the ditch must be now dug as at first, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch; all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it that this be done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone again, whereas what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge.

In the *plashing* the quick, two extremes are to be avoided; these are, the laying it too low, and the laying it too thick: this makes the sap run all into the shoots, and leaves the *plashes* without sufficient nourishment; which, with the thickness of the hedge, finally kills them. The other extreme of laying them too high, is equally to be avoided; for this carries up all the nourishment into the *plashes*, and so makes the shoots small and weak at the bottom, and, consequently, the hedge thin. This is a commen error in the north of England. The best hedges made any where in England, are those of Hertfordshire; and they are *plashed* in a middle way between the two extremes, and the cattle are by that prevented both from croping the young shoots, and from going thro'; and a new and vigorous hedge soon forms itself.

When the shoot is bent down that is intended to be *plashed*, it must be cut halfway thro' with the bill: the cut must be given sloping, somewhat downwards, and then it is to be wound about the stakes, and after this its superfluous branches are to be cut off, as they stand out at the sides of the hedge. If for the first year or two the field where a new hedge is made can be ploughed, it will thrive the better for it; but if the stubs are very old, it is best to cut them quite down, and to secure them with good dead hedges on both sides, till the shoots are grown up from them strong enough to *plash*; and wherever void spaces are seen, new sets are to be planted to fill them up. A new hedge raised from sets in the common way, generally requires *plashing* about eight or nine years after. *Mortimer's* Husbandry, p. 10.

PLASTER (*Cycl.*)—PLASTER, in pharmacy, an external application of a harder consistence than our ointments: these are to be spread according to the different circumstances of the wound, place, or patient, either upon linnen or leather. If the part upon which they are to be laid be naturally hairy, it must be shaved; but that they may stick the better, the natural shape of the part must be consulted, and the *plaster* spread and formed accordingly, either round, square, triangular, ellepticai, in a lunar form, or in shape of the letter T. Some also are divided at both ends, and others are perforated in the middle; these last are of frequent use in fractures attended with a wound; for by this contrivance the wound may be cleansed and dressed without removing the *plaster*. These *plasters* are of different forms, according to the part they are laid on; but they are usually square, or round; and indeed there is almost no part of the body which a *plaster* of one of those forms may not be made to serve for, if it be notched about the edges with a pair of scissers.

The uses of *plasters* are various; they are serviceable in securing the dressings, they also forward the maturation of the pus, agglutinate and heal wounds, unite broken bones, heal burns, assuage pain, and strengthen weak parts. *Heister's* Surg. p. 18.

PLASTER *of Paris*. The method of representing a face truly in *plaster of Paris*, is this: The person whose figure is designed is laid on his back, with any convenient thing to keep off the hair. Into each nostril is conveyed a conical piece of stiff paper, open at both ends, to allow of respiration. These tubes being anointed with oil, are supported by the hand of an assistant; then the face is lightly oiled over, and the eyes being kept shut, alabaster fresh calcined, and tempered to a thinnish consistence with water, is by spoonfuls nimbly thrown all over the face, till it lies near the thickness of an inch. This matter grows sensibly hot, and in about a quarter of an hour hardening into a kind of stony concretion; which being gently taken off represents, on its concave surface, the minutest part of the original face. In this a head of good clay may be moulded, and therein the eyes are to be opened, and other necessary amendments made. This second face being anointed with oil, a second mould of calcined alabaster is made, consisting of two parts joined lengthways along the ridge of the nose; and herein may be cast, with the same matter, a face extremely like the original. *Boyle's* Works, abr. Vol I. p. 132.

If finely powdered alabaster, or *plaster of Paris*, be put into a bason over a fire, it will, when hot, assume the appearance of a fluid, by rolling in waves, yielding to the touch, steaming, &c. all which properties it again loses on the departure of the heat; and being thrown upon paper, will not at all wet it, but immediately discover itself to be as motionless as before it was set over the fire; whereby it appears, that a heap of such little bodies, as are neither spherical, nor otherwise regularly shaped, nor small enough to be below the discernment of the eye, may, without fusion, be made fluid, barely by a sufficiently strong and various agitation of the particles which compose it; and, moreover,

over, lose its fluidity immediately upon the cessation thereof *Boyle's* Works abr. Vol. I. p 313.

Two or three spoonfuls of burnt alabaster, mixed up thin with water, in a short time coagulate, at the bottom of a vessel full of water, into a hard lump, notwithstanding the water that surrounded it. Artificers observe, that the coagulating property of burnt alabaster will be very much impaired or lost, if the powder be kept too long, especially if in the open air, before it is made use of; and when it hath been once tempered with water, and suffered to grow hard, they cannot by any burning or powdering of it again, make it serviceable for their purpose as before. *Boyle's* Works abr. Vol. I. p. 341.

This matter, when wrought into vessels, &c. is still of so loose and spungy a texture, that the air has easy passage thro' it. Mr. Boyle gives an account among his experiments with the air-pump, of his preparing a tube of this *plaster*, closed at one end and open at the other, and on applying the open end to the cement, as is usually done with the receivers, it was found utterly impossible to exhaust all the air out of it; for fresh air from without pressed in as fast as the other, or internal air, was exhausted, tho' the sides of the tube were of a considerable thickness. A tube of iron was then put on the engine; so that being filled with water, the tube of *plaster of Paris* was covered with it; and on using the pump, it was immediately seen, that the water passed through into it as easily as the air had done, when that was the ambient fluid. After this, trying it with Venice turpentine instead of water, the thing succeeded very well; and the tube might be perfectly exhausted, and would remain in that state several hours. After this, on pouring some hot oil upon the turpentine, the case was much altered; for the turpentine melting with this, that became a thinner fluid, and in this state capable of passing like water into the pores of the *plaster*. On taking away the tube after this, it was remarkable that the turpentine, which had pervaded and filled its pores, rendered it transparent, in the manner that water gives transparency to that singular stone called *oculus mundi*. In this manner, the weight of air, under proper management, will be capable of making several sorts of glues penetrate *plaster of Paris*; and not only this, but baked earth, wood, and all other bodies porous enough to admit water on this occasion. Philos. Trans. N°. 122.

PLASTERING. The modern taste runs greatly into *plastering*; and it were much to be wished that this art could be again brought to its antient perfection. In our best buildings the *plastered* walls and ceilings crack and fly, and in a little time grow damp, or moulder to decay. The Romans had an art of rendering their works of this kind much more firm and durable, and there is no reason to despair of reviving this art by proper trials.

The antient *plastering* of these people, preserved to this time, where it has not met with violent blows or injuries from accidents, is still found as firm and solid, as free from cracks or crevices, and as smooth and polished on the surface, as if made of marble. The bottoms and sides of the Roman aqueducts were made of this *plastering*, and endured many ages without hurt, unless by accidents; witness that whereof some yards are still to be found on the top of the Pont de Garde, near Nismes, for the support of which that famous bridge was built to carry water to the said town. The roofs of houses, and the floors of rooms at Venice are covered with a sort of *plaster*, made of later date, and yet strong enough to endure the sun and weather for several ages, without cracking or spoiling, and without much injury from people's feet.

The secret of preparing this Venetian *plaster* is not among us; but it would be worth while to try whether such a substance might not be made by boiling the powder of gypsum dry over the fire, for it will boil in the manner of water; and when this boiling or recalcining was over, the mixing with it resin, or pitch, or both together, with common sulphur, and the powder of sea-shells. If these were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till the instant of its being used, so that it might be laid on hot, it is possible this secret might be hit upon.

Wax and oil of turpentine may be also tried as additions: these being the common ingredients in such cements as we have accounts of as the firmest. Strong ale-wort is by some directed to be used, instead of water, to make mortar of limestone be of a more than ordinary strength. It is possible, that the use of this tenacious liquor to the powdered ingredients of this proposed *plaster*, might greatly add to their solidity and firmness. Phil. Trans. N°. 93.

PLAT *(Cycl.)*—PLAT-*veins*, in the manege, called in French *ars*, are the veins in which we bleed horses, one in the lower part of each shoulder, when we blood a horse in the shoulders; and in the flat part of the thighs.

PLATS, in a ship, flat ropes made of rope-yarn, and weaved one over the other: they serve to save the cable from galling in the hawse, or to wind about the flukes of the anchors, to save the pennant of the fore-sheet from galling against them.

PLATANUS, the *plane tree*. See PLANE-*tree*.

PLATÆ, a word used by some anatomical writers to express the scapulæ.

PLATAMON, a word used to express a low and smooth rock, just appearing above water.

PLATANARIA, in botany, a name by which some authors have called the *sparganium*, or burr-reed, from its round echinated fruit, which in shape and size much resemble those of the *platanus*.

PLATE, *(Cycl.)* a term used by our sportsmen to express the reward given to the best horse at our races.

The winning a *plate* is not a work of a few days to the owner of the horse, but great care and preparation are to be made for it, if there is any great dependance on the success. A month is the least time that can be allowed to draw the horse's body clear, and to refine his wind to that degree of perfection that is attainable by art.

It is first necessary to take an exact view of his body, whether he be low or high in flesh; and it is also necessary to consider, whether he be dull and heavy, or brisk and lively when abroad. If he appear dull and heavy, and there is reason to suppose it is owing to too hard riding; or, as the jockies express it, to some grease that has been dissolved in hunting, and has not been removed by scouring, then the proper remedy is half an ounce of diapente, given in a pint of good sack; this will at once remove the cause, and revive the creature's spirits. After this, for the first week of the month, he is to be fed with oats, bread, and split beans, giving him sometimes the one, and sometimes the other, as he likes best; and always leaving some in the locker, that he may feed at leisure when he is left alone. When the groom returns at the feeding time, whatever is left of this must be removed, and fresh given; by this means the creature will soon become high spirited, wanton, and full of play Every day he must be rode out an airing, and every other day it will be proper to give him a little more exercise; but not so much as to make him sweat too much.

The beans and oats in this case are to be put into a bag, and beaten till the hulls are all off, and then winnowed clean; and the bread, instead of being chipped in the common way, is to have the crust clean cut off

If the horse be in good flesh and spirits when taken up for its month's preparation, the diapente must be omitted; and the chief business will be to give him good food, and so much exercise as will keep him in wind, without over sweating or tiring his spirits. When he takes larger exercises afterwards, towards the end of the month, it will be proper to have some horses in the place to run against him. This will put him upon his mettle, and the beating them will give him spirits.

This, however, is to be cautiously observed, that he has not a bloody heat given him for ten days or a fortnight before the *plate* is to be run for; and that the last heat that is given him the day before the race, must be in his cloaths: this will make him run with greatly more vigour, when stripped for the race, and feeling the cold wind on every part. In the second week the horse should have the same food and more exercise, and in the last fortnight he must have dried oats, that have been hulled by beating; after this they are to be wetted in a quantity of whites of eggs, beaten up, and then laid out in the sun to dry; and when as dry as before, the horse is to have them. This sort of food is very light of digestion, and very good for the creature's wind. The beans in this time should be given more sparingly, and the bread should be made of three parts wheat, and one part beans. If he should become costive under this course, he must then have some ale and whites of eggs beaten together: this will cool him, and keep his body moist.

In the last week the mash is to be omitted, and barley-water given him in its place, and every day, till the day before the race: he should have his fill of hay, then he must have it given him more sparingly, that he may have time to digest it; and in the morning of the race-day, he must have a toast or two of white bread, soaked in sack, and the same just before he is led out to the field. This is an excellent method, because the two extremes of fullness and fasting are at this time to be equally avoided; the one hurting his wind, and the other occasioning faintness, that may make him lose. After he has had his food, the litter is to be shook up, and the stable kept quiet, that he may be disturbed by nothing till he is taken out to run.

PLATES, in gunnery. The *prise-plates* are two *plates* of iron on the cheeks of a gun-carriage, from the cape-square to the center, through which the prise-bolts go, and on which the hand-spike rests when it poises up the breech of the piece. Breast-*plates* are the two *plates* on the face of the carriage, one on each cheek. Train-*plates* are the two *plates* on the cheeks at the train of the carriage. Dulidge-*plates* are the six *plates* on the wheel of a gun-carriage, where the fellows are joined together, and serve to strengthen the dulidges.

PLATE-*longe*, in the manege, a woven strap, four fathom long, three fingers broad, and as thick as one. It is used for raising a horse's legs and sometimes for taking him down, in order to facilitate several operations of the farrier. Some improperly give the name of *plate-longe* to a martingale. See the article MARTINGALE, *Cycl.*

PLATEA, in zoology, the name of a bird of the long-necked kind, approaching to the nature of the stork and heron, and called

called in English the *spoon-bill*, from the remarkable figure of its beak, which is different from that of all other birds; being broadest at the extremity, and terminating in a large rounded, flat process. resembling a shovel; or, if it were hollow, a spoon. See Tab. of Birds, N°. 42.

This bird has been called *lucoredius*, *albardeola*, and *le'elaer*, and by some very improperly the *pelecanus*. It is all over very white, like the swan; but that there is some blacknefs in the wings It builds in high trees in some parts of Holland. *Ray*'s Ornithology. p. 212.

PLATESSA, in zoology, a name by which Aufonius and some other authors have called the paffer-fifh, or common plaife. *Willughby*'s Hift. Pifc. p. 96.

PLATFORM (*Cycl.*)—All practitioners are agreed, that no fhot can be depended on, unlefs the piece be placed on a folid *platform*; for if the *platform* fhakes with the firft impulfe of the powder, it is impoffible but the piece muft likewife fhake; which will alter its direction, and render its fhot uncertain. To prevent this accident, the *platform* is ufually made extremely firm to a confiderable depth backwards, fo that the piece is not only well fupported in the beginning of its motion, but likewife through a great part of its recoil. However, it is fufficiently obvious, that when the bullet is feparated from the piece, it can be no longer affected by the trembling of the piece or *platform*; and by a very eafy computation it will be found, that in a piece ten feet in length, carrying a bullet of 24 lb. and charged with 16 lb. of powder, the bullet will be out of the piece before it has recoiled half an inch; whence if the *platform* be fufficiently folid at the beginning of the recoil, the remaining part of it may be much flighter, fince its unfteadinefs beyond the firft half inch will have no influence on the direction of the fhot: and hence a more compendious method of conftructing *platforms* may be found out. New Princip. of Gunn. p. 42.

PLATIASMOS, a word ufed by many authors to exprefs a fault in pronunciation, owing to a perfon's opening his mouth too wide, and thence fpeaking indiftinctly.

PLATICORIA, a word ufed by medical writers to exprefs a preternatural dilatation of the pupil of the eye, ufually owing to a paralytic diforder.

PLATONIA, in natural hiftory, a name given by the modern Greeks to the *prox* of Ariftotle, and of other antient writers in that language. This is the *cervus platyceros*, or broad-horned ftag. Some have tranflated this *dama*, but they are to be underftood in this as meaning the *dama* of their own times, not that of the antients; that being the *ifarus*, or chamoy-goat, not any animal of the ftag kind, nor by any means meriting that title.

PLATYCERCOS *ovis*, in natural hiftory, the name given by Gefner and fome others to a fpecies of fheep, commonly called *ovis laticauda*, or the broad-tailed fheep.

The tail of this creature is very thick, broad, and heavy, weighing often thirty pounds. We fometimes fee it brought over hither as a fhew, and find that authors have defcribed the fhape of its tail very inaccurately. Caius, in Gefner, fays it is of the fhape of the tails of other fheep, broad at the infertion, and growing gradually fmaller to the end; but it is exactly the contrary of this, being narroweft at the infertion, and growing fomewhat larger and broader to the extremity; fo that on the whole, it reprefents a fort of bag or purfe. The creature is not uncommon in Ægypt, Africa, and Arabia, and in fome parts of Syria. *Ray*'s Syn. Quad. p. 74. See the article Macrocercos.

PLATYOPHTHALMON, a name given by fome to antimony, from its ufe among the ladies of old time, to make their eye brows broad and black

PLATYSTERNOS a word ufed by the old phyficians to exprefs a perfon with a very broad cheft or fternum.

PLATYRYNCHOS, in zoology, a name given by fome to the *nafus*, or *nefe*, a frefh water fifh, caught in the Danube, and moft of the large rivers in Germany, and much refembling the chub *Gefner* de Pifc. p. 213. See the article Nasus.

PLATYSMA *myodes*, in anatomy, a name given by Fallopius to one of the mufcles called by Albinus *latiffimus colli*, and by others *quadratus genæ*.

PLAUSUS, among the Romans. See Acclamation.

PLEA (*Cycl.*)—Plea, in abatement. See the article Abatement, *Cycl.*

PLEADING. Among the Athenians, an equal time was allowed both parties to *plead*, which was meafured by a water hour-glafs; and in order to fee juftice done in this refpect, there was an officer appointed to diftribute the water to each, whence he was called *ephydor*. Pott Arch. Græc. l. 1. c. 21 See Ephydor

PLEASURE-*boat*, among the antients. See Thalamegus.

PLECHAS, a word ufed by Hippocrates, to exprefs that region of the body which is terminated backward by the anus, forward by the pudenda, and fideways by the hips.

PLECTANÆ, a word ufed by fome to exprefs the cornua uteri, and by others for any plexus of veffels.

PLECTRONITÆ. See the article Conichthyodontes.

PLECTRUM, a word ufed by fome anatomical writers, to exprefs the ftyloide procefs of the os petrofum; by others for the uvula; and by others for the tongue.

Plectrum, among the antients, an inftrument ufed in playing upon the lyre. We have a defcription of it in Mem. Acad. Infcrip. Vol. V. p. 168, 169. See Lyre, *Cycl.*

PLEMMYROS, a word ufed by the old Greek writers to exprefs a redundance of humors: its proper fignification is the flowing in of the tide.

PLENNA, a word ufed by fome writers to exprefs any mucous humor.

PLEROSIS, a word ufed by the old Greeks to exprefs the repletion or reftoring the body to its natural ftate, after it has been emaciated by ficknefs.

PLESMONE, a word ufed by the antients to fignify plenitude or fatiety.

PLESTYA, in zoology, a name given by Bellonius to a frefh water fifh of the leather-mouthed kind, appearing to be no way effentially different from the more common kind of carcafius, called by authors *carcaffii tertium genus*. *Ray*'s Ichthyogr. p. 250. See Carcassius.

PLETHORA (*Cycl.*)—Medical writers now ufually diftinguifh four kinds of a *plethora*. 1. The fimple *plethora*, which is that ftate of the body in which the blood is too abundant in quantity, but is as yet of no bad quality. 2. The cacochymious *plethora*, which is that where the blood is abundant in quantity, and at the fame time is fubject to a too great thicknefs, or fome other dyfcracy. 3. The *plethora ad vafa*, whereby the blood, from its over great quantity, renders the veffels turgid, without any farther ill effect. And, 4. The *plethora ad vires*, in which there is joined to too great a plenitude of the veffels, a laffitude, and torpor, or numbnefs of the limbs.

The figns of a *plethora* are, 1. A florid conftitution of the body. 2. A tolerable ufe of the non-naturals, a good appetite to food, and a found fleep: this is the cafe while the *plethora* is fimple and unmoved, but when any commotion happens from without, the figns are inquietude at night, dreams of bleeding, and of wounds from fwords or other weapons, rubicund looks in the face, and a general turgefcence of the veffels, a heavinefs of the limbs, an inaptitude to motion, and difficulty of breathing, a vertiginous diforder of the head, a fenfe of a pricking or tingling in the flefh from the flighteft heat, an eafy heating of the body from the weather, a moifture of the eyes, and in hyfteric women a fenfation as if a piece of cold ice were fuddenly laid on fome part of the head.

Perfons moft fubject to a Plethora, are, 1. People of fedentary lives, who live high. 2. The younger rather than perfons more advanced in years. 3. The female fex rather than the men. 4. All perfons who have been accuftomed to large evacuations, and have haftily fuppreffed them. And, 5. Thofe perfons who have fuddenly changed a life of labour or exercife to a fedentary one, without making the neceffary changes in the non-naturals.

Prognoftics from a Plethora. 1. *Plethoric* perfons are more fubject to difeafes in general than others. 2. They are particularly fubject to hæmorrhages, inflammations, and acute fevers. 3. The lighter difeafes coming upon perfons of a *plethoric* habit, are ufually more ftubborn and dangerous than on others. 4. The *plethora* itfelf can fcarcely be called a difeafe, but it is the parent of many difeafes Chronic difeafes are with more difficulty cured in *plethoric* patients than in others, becaufe they are always averfe to exercife. 6. A *plethoric* habit, difturbed by violent motion, by paffions of the mind, or by ftimulating medicines, is capable of producing very terrible confequences. 7. The difeafes arifing from a *plethora*, from ftopping fome accuftomed evacuation, are with difficulty cured; and *plethoras* are more efficacioufly relieved by natural hæmorrhages than by any artificial means.

Method of cure in a Plethora. A fimple *plethora* is eafily removed by bleeding and gentle exercife, and by a more fpare diet; to thefe may be added, gentle purging once a month. The *plethora* with a cacochymy requires gentle purging, bleeding, and cuping, diaphoretics and diuretics. If a violent commotion of the blood happen with a *plethora*, temperance is to be firft prefcribed, then the ufe of nitre, and crabs-eyes faturated with lemon juice; and other cooling and alterative remedies. *Junker*'s Confpect Medic. p. 4.

PLEURISY *and* PERIPNEUMONY (*Cycl.*)—Thefe are two difeafes which have fome refemblance in their general fymptoms, and are thence fometimes miftaken one for the other. They are, however, extremely different in their place of origin, as well as in their feveral fymptoms: the *pleurify* being a ftafis of blood in the *pleura*; and the *peripneumony* a ftafis of the fame fluid in the lungs They are both attended with an acute, continuous, and inflammatory fever, by means of which nature is labouring to break through the obftruction made by the ftafis of the blood in thofe parts.

The fpurious *pleurify* is to be carefully diftinguifhed from thefe two difeafes. In the true *pleurify*, or *peripneumony*, a pain is felt either about or a little below the nipple; but the fpurious *pleurify* generally fhews itfelf higher, ufually about the clavicle. In the genuine difeafes the pains are equal and regular, anfwering to the pulfe: in the fpurious *pleurify* they are vague, and wholly irregular. In the true, they are alfo continual; but in the fpurious, they have frequent intermiffions and remiffions. The true have always a cough attending them, and

that usually attended with a spitting of coloured matter, often streaked with blood; but the spurious often has no cough at all attending it; or if it has, there is no difference seen in the matter voided by spitting. The true has always an acute continuous fever, which attacks the patient at first with a shivering; the spurious either has no fever at all with it, or it is at the utmost a slight and irregular one.

The true diseases do not terminate in less than seven days; the others much sooner. The true usually attack young people; the spurious are common to young and old. The difference between the true and spurious diseases, are determined by the observation of these symptoms; but it yet remains to distinguish justly the true diseases from one another. This is done by the following observations:

The *pleurisy* is a very rare disease; and the *peripneumony* a very common one; but this is exactly contrary to the common opinion, from these diseases being too generally confounded with, and mistaken for one another.

In a *peripneumony*, a spitting of blood usually happens about the close of the second day: this is a primary symptom in a *peripneumony*, but is usually erroneously attributed to a *pleurisy*, tho' reason shews how easily such a spitting may happen from an inflammation of the lungs; and it is very different to conceive how it should happen so readily from an inflammation of a part so remote from having any communication with the organs of expectoration as the pleura.

In the *peripneumony*, the pain extends itself farther, affecting the whole breast, whereas in the *pleurisy* it is rather fixed to the right side, and felt a little below the breast. These are the symptoms by which these diseases are distinguished from one another, and the use of the distinction is principally this, that in the *pleurisy* the application of external remedies often is of great service, whereas it is of no effect in the other case, tho' the mistake is of no great consequence in this respect as the applications in the *peripneumony* can do no harm: but in an unhappy termination of these diseases by suppuration, the distinction becomes of some consequence; since in the *pleurisy* the matter may be evacuated by a paracentesis, or the letting in a canula; which in the *peripneumony* can by no means be done, unless in such an accidental case that the disease terminates in an external *vomica pulmonum*: then indeed the matter being discharged from the abscess into the cavity of the thorax, may be let out in the same manner as in the suppurated *pleurisy*; but this is a case that does not occur in an age.

The usual opinion of medical writers, in regard to this case, is, that the *peripneumony* is always a disorder affecting only the external surface of the lungs; and they observe, that even its name expresses this, the signification of it being a distemperature spreading round about the lungs: this, however, is not agreeable to observation or experience; for in dissections of bodies that have died of this disease, the very internal part of the lungs is always found affected; and indeed if the surface only were so, it is not easy to conceive how the spitting of blood should come on so soon as the second day.

Signs of these diseases. These are in general common to both, and are the following: A vertiginous disorder of the head usually precedes all the other symptoms; this is succeeded by a shivering and chillness all over the body; this increases by degrees, and usually brings on with it cardialgias, nauseas, and anxieties: after this there comes on a very remarkable heat, with very intense thirst, and a violent pain in the head; this is accompanyed with a straitness of the breast, and difficulty of respiration; and the patient feels a violent and severe pain in the breast: and this becomes continual, and is always greatly exasperated by the cough that attends the disease. The urine in the first days is red, and after a few days more it becomes turbid, when it has stood to be cold; and finally deposits a thick pale-red sediment. The peculiar symptoms of each disease are already enumerated.

Persons subject to them. These are diseases not equally common to all ages, but they principally affect young people: they are most frequent in the beginning of the spring season, and mostly affect such as are of a sanguine plethoric habit. Persons who have been subject to bleeding at the nose, but have been for some time free from returns of them, often fall into these diseases; and in general men are much more subject to them than women.

Causes of them. These diseases are brought on by any thing that gives a violent commotion to the blood, such as immoderate exercise, the abuse of spiritous liquors, and violent fits of anger. The suddenly cooling the body when very hot, has also often occasioned them, by shutting the pores and forcing the blood inwards. The neglect of habitual bleedings may also occasion them; and they have been sometimes occasioned by blows, or other external injuries on the breast, and by the endeavouring to lift great weights.

Prognostics in them. All inflammatory fevers are dangerous; but the *pleurisy* and *peripneumony*, when they attack young persons, or such as are under thirty years of age, are attended with the least danger of any, provided that they are properly treated: when they affect persons advanced in years, they usually prove very dangerous, in spite of all the care and caution that they can be treated with.

When they have been treated in a judicious manner, they usually go off on the seventh, or at the utmost the eleventh day in copious sweats, which come on of themselves; after this crisis, the pulse in a very little time returns to its natural state, the violent heat goes off, and the strength, appetite, and sleep, return. When they go beyond the days of their crises, which is often the case in old people, they then become very dangerous. If the urine is observed to be turbid before the fourth day, and afterwards deposits a sediment, and the rest remain clear at the top, there is great hope that the disease will terminate happily, on the critical day, by a sweat. When a yellowish matter is thrown up by coughing, and is neither very viscid nor frothy, and particularly when in a *peripneumony* it is streaked with blood, there is great reason to expect that the disease will go happily off: but, on the contrary, when the patient cannot spit at all, and the urine continues crude, there is great reason to fear the disease will have a fatal period.

Finally, when a discussion and resolution of the stasis cannot be effected by nature, or obtained by art, a corruption and suppuration follows, and often an ulcerous disposition of the lungs, or true phthisis is the consequence.

Method of cure. The bowels are to be kept gently lax, during the whole course of the disease; but no irritating medicines must by any means be given to promote this. When there is a remarkable plethora with a narrowness of the breast, and a sensible stuffing up of the lungs, then bleeding is necessary; but a small quantity only should be taken away, and the same repeated the next day or oftener, if the same symptoms continue to require it: always after bleeding the patient must take some gently diaphoretic medicines, and drink plentifully of warm and weak liquors. In the usual and more common cases, bleeding is not necessary in these diseases, tho' so greatly recommended by some. Every day before noon it is proper to give two doses of the mixtura simplex, or some other such temperate diaphoretic, with large draughts of warm liquors; and in the afternoons the antifebrific powders of nitre, diaphoretic antimony, crabs eyes sated with lemon juice should be given; and emulsions are also very proper, made of sweet almonds and barley water, or of the seeds of carduus mariæ. When these medicines have been given for some days, if the pain continues still violent, the tincture of cascarilla must be taken; and in cases of the *pleurisy* cloths four or more times doubled and wetted in camphorated spirit of wine, are to be applied to the part. Plasters may also be applied occasionally, but they must not be suffered to remain on too long, lest they stop respiration; an equal regimen and perfect quietness is to be observed during the whole time of the disease; but particularly on the critical days, on which nature must be by no means ruffled or disturbed.

Authors differ greatly in their opinions about bleeding in this disease: some judge it absolutely necessary in all cases; and others wholly reject it in all. Etmuller observed, that bleeding in these diseases always gave the stasis a tendency to suppuration; others are of opinion, that it is to be done, or omitted, according to the peculiar indications in the case; and some throw aside all the dissolvent and discutient medicines, and rely on the volatile salts alone for the promoting sweats, and accomplishing the cure by that means alone, only observing, that if the disease will not yield to these, bleeding is to be added.

But the more rational practice seems to determine, that it is a rash attempt to endeavour to discuss a stasis already formed by hot medicines, which expand the blood, and seem calculated only to add to it; and that the natural state of the disease does not indicate bleeding, tho' the urgency of certain symptoms, such as straitness of the breast and infarctions of the lungs, in persons of plethoric habits, may render it necessary and beneficial.

Persons of very plethoric habits, who have died of these distempers, on dissection, have been found to have one side of the lungs so stuffed up with blood, that it would sink in water; and unquestionably in such cases bleeding is necessary.

Sydenham's method of curing by large and often repeated bleedings, and the use of gentle expectorants, is found very dangerous in its effects, and seems the only reproachable thing in the works of that excellent writer. And tho' Riverius gives an instance of a person cured of a *pleurisy* in a few hours, by bleeding alone, the account does not seem wholly to be depended upon; for some circumstances in the relation seem to shew, that the disease was not properly either a *pleurisy*, or a *peripneumony*, but an inflammation of the liver or stomach. Some people recommend the flowers of the common red poppies in these cases, as a specific remedy; but Etmuller allows them no such quality, but says they act in this case merely as a gentle opiate and anodyne; a sort of medicines very dangerous in these cases.

The seeds of carduus mariæ, or the milk thistle, are also by some recommended as specifics: it is very evident that they mitigate the pain; but the fever will always continue to its regular period on the seventh day.

Expectorating medicines, in general, are of no use in these cases, only if the spitting of a bloody matter do not succeed sufficient-

sufficiently by the fourth day, it may be neceſſary to give a doſe or two of ſomething of this kind; and to this purpoſe a decoction of hyſſop is preferred by many before all other medicines. Nitre is to be given boldly for the four firſt days; but after this, if the diſeaſe go on regularly, it is to be given in ſmaller quantities, and not oftener than twice in a day. All oily and fatty ſubſtances are to be excluded from external uſe, but camphor in any form is found to do ſervice.

Opiates in theſe caſes are dangerous; for as there is in all of them a tenacity of the blood, this ſtate of it requires concuſſion, reſolution, and excretion, but opiates effect the exact contrary of all theſe. Caſcarilla properly given, will almoſt always mitigate the pain; and when that fails of it effect it is certain that opiates cannot procure it, but muſt inevitably do harm. *Junck.* Conſp. Med. p. 297, ſeq.

Mr. Du Hamel found the polygala vulgaris of ſervice in promoting expectoration in *pleuriſies*. Med de l'Acad. Science. 1739.

Bliſters too, on the part affected, are ſaid to give great relief.

PLEUROCYSTUS, in natural hiſtory, the name of one of the general arrangements of the echini marini.

The word is derived from the Greek πλευρον, the ſide, and κυσις the anus.

The echini of this diviſion are diſtinguiſhed from the others, by having their anus neither on the ſummit, nor in any part of the baſe, but in ſome part of the ſuperficies of one of the ſides. *Klein's* Echin. p. 32.

PLEURONECTES, in ichthyology, the name of a genus of fiſhes of the malacopterygious kind, the characters of which are theſe: The branchioſtege membrane, on each ſide, contains ſix bones of a cylindric figure; and in the middle between theſe, but lower down, there are two others joined together at the end, but theſe are ſcarce conſpicuous. Both the eyes are placed in one ſide of the head; in ſome they are in the right ſide, and in others in the left. The eyes are covered with a ſkin. One ſide of the fiſh is always white, the other is ſpotted or obſcure.

Of theſe fiſh there are ſome which have a very ſhort ſpine at the anus, and the eyes uſually on the right ſide. The ſpecies of this ſort, enumerated by Artedi, are theſe: 1. The *pleuronectes oculis et tuberculis ſexa dextra capitis, lateribus glabris, ſpina ad anum:* this is the *plaiſe*. 2. The *pleuronectes* with the eyes on the right ſide, with rough ſcales, a ſpine at the anus, and obtuſe teeth. This is the fiſh we in England call the *dab*. 3. The *pleuronectes* with the eyes on the right ſide, altogether ſmooth. This is the *hippogloſſus* of Rondeletius; it is about a foot long. 4. The *pleuronectes* with the eyes on the right ſide, with the lateral lines rough, with obtuſe teeth, and with little ſpines at the origin of the fins. This is our *flounder*. 5. The *pleuronectes* with the eyes on the right ſide, with ſharp teeth and with the anus on the left ſide. This is the fiſh called *linguatula* at Rome, and the *pola* of Bellonius. 6. The oblong *pleuronectes* with the upper jaw longeſt, and ſcales rough on each ſide. This is the *bugloſſus* of authors, or the *ſole*. 7. The *pleuronectes* with the eyes on the right ſide, with a rough hoary body, and the lateral fins ſcarce viſible. This is brought from Amboina.

The other ſeries of the *pleuronectæ* have their eyes on the left ſide of the head, and have no ſpine, or ſcarce any at the anus. Of theſe Artedi enumerates the following ſpecies: 1. The ſmooth *pleuronectes*, with the eyes on the left ſide. This is the *rhombus non aculeatus* of Willughby, and is called the *pearl* in ſome parts of England, in Cornwall the *lugaleaf*. 2. The rough-bodied *pleuronectes*, with the eyes on the left ſide. This is our common *turbott*. 3. The left ſide-eyed *pleuronectes*, with prickly lateral lines. This is the *rhombus aculeatus* of authors. The lines on the ſide where the eyes are, are only prickly. *Artedi*, Gen. Piſc. 14.

The name is of Greek origin, and is derived from the words πλευρον, the ſide, and νηκτης, a ſwimmer; and expreſſes the peculiar and diſtinctive character of theſe fiſhes; which is, that they all ſwim on one ſide, not as other fiſhes.

PLEUROPNEUMONY, a name given by medical writers to a diſeaſe approaching to, and partaking of the nature of both the pleuriſy and peripneumony.

PLEURORTHNOPŒA, a term uſed by medical writers to expreſs that kind of pleuriſy in which the patient cannot breathe, unleſs in an erect poſture.

PLICARIA, in botany, a name uſed by ſome for the club-moſs. *Dale*, Pharm. 60.

PLICATED *leaf*, among botaniſts. See LEAF.

PLINIA, in botany, the name of a genus of plants, deſcribed by Plumier and Linnæus, the characters of which are theſe: The perianthium is ſmall, plane, and conſiſts of one leaf; the flower conſiſts alſo of one petal, which is plane, and is divided into five equal parts; the ſtamina are numerous filaments, very ſlender, and of the length of the flower; the antheræ are ſmall; the germen of the piſtil is ſmall; the ſtyle is ſubulated, and of the length of the ſtamina; the ſtigma is ſimple; the fruit is a large globoſe berry, of a ſtriated or ſulcated ſurface, containing only one cell, in which is a very large, ſmooth and globoſe ſeed. *Linnæi* Gen. Pl. 239. *Plumier*, Gen. 11.

PLINTHITIS, a kind of alum found in ſome of the iſlands of the Archipelago, and called alſo *placitis*, from its uſually being found in thin cakes.

PLINTHIUM, a name given by the antients to a machine invented for the making extenſion of diſlocated or fractured limbs. Oribaſius deſcribes ſeveral kinds.

PLITE *of lawn*, in our old writers, ſeems to be an antient meaſure, as a yard or ell, at this time: 'tis mentioned in the Stat. Ed. IV c. 5. *Blount*.

PLOMO, in metallurgy, a name given by the Spaniards, who have the care of the ſilver mines, to the ore of that metal when it is found adhering to the ſurface of ſtones, and incruſting their cracks and cavities in the form of ſmall and looſe grains of gunpowder. Tho' theſe grains be but few in number, and the reſt of the ſtone have no ſilver in it, yet they are always very happy in meeting with it, as it is a certain token that there is a very rich vein ſomewhere in the neighbourhood. And if in digging forwards they ſtill meet with theſe grains, or the *plomo* in greater quantity, it is a certain ſign that they are getting more and more near the good vein.

PLONKETS, in our old writers, a kind of coarſe woollen cloth. 1 Rich. III c 8. *Blount*, *Cowel*.

PLOTTING (*Cycl.*) – PLOTTING-*table*, in ſurveying, is uſed for a plain *table*, as improved by Mr. Beighten, who has obviated a good many inconveniencies attending the uſe of the common plain *table* See Phil. Tranſ Nº 461. Sect. 1.

PLOVER, *pluvialis*, in zoology. See the article PLUVIALIS.

This bird uſually flies in exceedingly large flocks in the places they frequent; people talk of twenty or thirty thouſand being ſeen in a flock. They generally come to us in September, and leave us about the end of March. In cold weather they are found very commonly on lands lying near the ſea, in queſt of food; but in thaws and open ſeaſons, they go higher up in the country.

They love to feed in ploughed lands, but never remain long at a time on them, for they are very cleanly in their nature; and the dirt which lodges on their beaks and feet, gives them ſo much uneaſineſs, that they fly to the neareſt water to waſh themſelves. When they rooſt, they do not go to trees or hedges, but ſit ſquatting on the ground like ducks or geeſe, far from trees or hedges, when the weather is calm; but when it is ſtormy they often get under ſhelter. In wet weather they do not ſleep in the night at all, but run about picking up the worms as they crawl out of the ground: during this feeding they are continually making a ſmall cry, that ſerves to keep them together, and in the morning they take flight. If in their flight they ſpy any others on the ground, they call them up; and if they refuſe to come, the whole body deſcends to ſee what food there is in the place that detains them.

The *plover* are very eaſily taken at the time of their firſt coming over, when they have not got any other birds mixed among them; but when they afterwards pick up the teal and other ſhy birds among them, it becomes more difficult. The beſt ſeaſon for taking them is in October; eſpecially in the beginning of that month: after this they grow timorous, and are not eaſily taken again till March, which is the time of their coupling. The ſevereſt froſts are not the beſt ſeaſon for taking them in neſts, but variable weather does better. The north weſt wind is found diſadvantageous to the taking of them; and in general great regard is to be paid to the courſe of the wind in the ſetting of the nets. All ſea-fowl fly againſt the wind when the land lies that way; and the nets for the taking them are therefore to be placed in a proper direction accordingly.

PLOVER-*ſtone*, in zoology, a name uſed in ſome parts of England for the godwit, or *ægocephalus* of authors. See the article ÆGOCEPHALUS.

PLOUGH (*Cycl.*)—The advantage of digging with the ſpade, or ſuch other inſtrument, very naturally led men to the invention of the *plough*, as a greatly more expeditious way of doing the ſame thing; that is, cutting and breaking the earth into ſmall pieces; but in this the ſpade has the advantage of the common *plough*, as it goes deeper, and divides the earth more minutely; but the improvement of the common *plough* into the four coultered one, ſhews that it is eaſy to make the *plough* perform this office as much better, as it uſually does it worſe than the ſpade.

The *plough* deſcribed by Virgil had no coulter; and at this time the *ploughs* in Italy and the ſouth of France, have none; and the *ploughs* in Greece, and in the eaſtern nations in general, are of the ſame kind Neither is it indeed poſſible to uſe a coulter in ſuch a *plough*; becauſe the ſhare does not cut the bottom of the furrow horizontally, but obliquely: in going one way it turns off the furrow to the right hand, but in coming back it turns it off to the left; therefore if it had a coulter, it muſt be on the wrong ſide every other furrow.

It is a great miſtake in thoſe who ſay that Virgil's *plough* had two earth-boards, for it had really none at all; but the ſhare itſelf always going obliquely, ſerved inſtead of an earth-board; and the two ears, which were the corners of a piece of wood lying under the ſhares, did the office of ground-wriſts. This faſhion of the *plough* continues to this day in thoſe countries; and in Languedoc this ſort of *plough* performs tolerably

bly well when the ground is fine, and makes a ſhift to break up light land. This is the ſort of land that is common in the Eaſt, and the arable lands about Rome, being never ſuffered to be fallow ſo long as to come to turf: this *plough* ſucceeds very well in ſuch places, but it would be wholly impoſſible to turn up what in England we call ſtrong land, with it.

The Engliſh *ploughs* are therefore different from theſe, as the ſoil is different. Our *ploughs*, where well made, cut off the furrow at the bottom horizontally; and therefore, it being as thick on the land ſide as on the furrow ſide, the *ploughs* cannot break it off from the whole land at ſuch a thickneſs (being ſix times greater than what the eaſtern *ploughs* have to break off) and for this purpoſe it muſt have, of neceſſity, a coulter to cut it off: by this means the furrow is turned perfectly whole, and no part of the turf of it is broken; and if it lie long without new turning, the graſs from the edges will ſpread, and form a new turf on the other ſide, which was the bottom of the furrow before the turning; but is now become the ſurface of the earth, and will ſoon become greener with graſs than it was before *ploughing*.

If whole, ſtrong, turfy furrows are *ploughed* croſs-ways, as is too commonly practiſed, the coulter cannot eaſily cut them; becauſe being looſe underneath, they do not make a proper reſiſtance or preſſure againſt its edge, but are apt to be drawn on heaps, and turned in all directions, but without cutting.

Some of our *ploughs* have heavy drags, with long iron tines in them; and tho' theſe broken pieces of furrows, being now looſer than before, require keener edges to cut them, theſe tines have no edges at all. Thus the clods of earth are toſſed into heaps again, and the ſurface left bare between them, and great labour and expence is uſed to very little purpoſe: all this is owing to the one coulter.

If the ſoil be ſhallow, it may be broken up with a narrow furrow, which will the ſooner be brought into tilth; but if it be a deep ſoil, the furrows muſt be proportionably enlarged, or elſe a great part of the good mould will be left unmoved, and ſo be loſt. The deeper the land is, the worſe it is broke by one coulter; that is, it is broke into larger furrows, and it requires ſuch repeated labour to conquer this, that often the beſt land will ſcarce pay the tillage.

This gives an opportunity to ſervants to cheat their maſters. They *plough* ſuch deep land with a ſmall furrow, and ſhallow, to the end that the turf and furrows may be broken the ſooner, and the ſuperficial part made fine. They pretend the *plough* will go deeper the next time; but this is never the caſe.

This ſort of land muſt not be *ploughed* the ſecond time in wet weather; for this will cauſe the weeds to multiply, and the earth will be formed into thick and heavy clods where trodden: and in dry weather, the reſiſtance of the untouched earth below, and the ſlight preſſure of the *plough* above, will always be reaſons why the *plough* will enter no deeper the ſecond time than it did the firſt.

Another way to conquer a ſtrong turf, is to plow it up firſt with a *breaſt-plough*, very thin; and when the ſwerd is rotten, then it is to be *ploughed* to the proper depth: but this method is liable to great objections; it is very troubleſome and expenſive, and if the turf be pared off in the winter, or early in ſpring, it is a chance but the rains come on, and ſet it to growing faſter than before: if, on the other hand, it be pared later in the year, tho' the turf be thoroughly killed by the ſucceeding dry weather, yet the time is loſt, and the farmer loſes the ſowing ſeaſon for wheat, which is the proper corn for ſuch ſtrong land.

The four-coultered *plough* is the proper inſtrument for the farmer to have recourſe to on this and many other the like occaſions. This is an improvement on the common *plough*, that makes it cut the pieces of earth into four; that is, it thus divides the earth four times as ſmall as the common *plough*.

The common two wheeled *plough* has of late years become univerſally uſed in many counties, and is found greatly preferable to the *ploughs* they uſed before; there is an objection to it, indeed, in regard to ſome ſtiff and miry lands, in which the wheels become clogged up, and cannot turn. This, however, is eaſily remedied by twiſting thumb ropes of ſtraw about the iron circle and ſpokes of the wheels; theſe ſpreading as they turn, and as the circle twiſt bears upon the ground, throw off the dirt, and never clog. The two principal parts of this *plough* are the head and the tail: the *plough*-head contains the two wheels and their axis, or ſpindle, paſſing through a box, and turning round both in it and in the wheels. There are fixed perpendicularly in this box, two crow-ſtaves, as they are called, which are flat and narrow boards, each having on it two rows of holes, whereby to raiſe or ſink the beam of the *plough*, by pinning up or down the pillow, to increaſe or diminiſh the depth of the furrow. Behind are a pair of gallows, through which the crow-ſtaves paſs at the top by mortaiſes, into which they are pinned; and to theſe are faſtened what are called the wilds, which are rings and crooks of iron, by which the whole *plough* is drawn in the working. From the box to the center of the beam there is carried an iron-chain, conſiſting of four, five, or more long links, and called the tow-chain: this faſtens the *plough*-tail to the *plough*-head. It is fixed to an iron collar, faſtened in the beam at one end, and at the other paſſes through a hole in the middle of the box, and is pinned in with a wooden pin.

From the ſame iron-collar to which the tow-chain is fixed, there is alſo another chain faſtened, called the bridle-chain: this runs above the beam, as the tow-chain does below it, and is compoſed of ſmaller and more numerous links. At the upper end, as the tow-chain enters the box of the *plough*, this bridle-chain is fixed to the top of what is called the ſtake of the *plough*: this is a perpendicular ſtick, carried up parallel with the left crow-ſtaff, and pretty near it, and faſtened to it by a wyth or rope, or by the end of the bridle-chain itſelf, when that is long enough. This ſtake is alſo faſtened in its lower part, under the gallows, to the ſame crow-ſtaff, by another wyth or piece of rope.

Theſe are the parts of which the head-part of the *plough* is compoſed. The *plough*-tail conſiſts of the beam carried from the head to the very extremity, and ſerving as the ſupport and baſe of all the reſt. A little below the collar to which the tow-chain and bridle chain are faſtened, this beam is pierced with a large hole, which lets through the coulter: this is a long and narrow piece, terminating in an edge, and reaching juſt to the ſhare; and it is fixed immoveably in its place by means of a wedge which is driven into the hole of the beam with it: the office of this coulter is to cut the earth as it is thrown up by the ſhare. Behind theſe, the ſame beam is pierced with two more holes, one very near its end: theſe give paſſage to two oblong pieces, called the fore-ſheat and hinder-ſheat, by which the *plough*-ſhare is ſupported in its place. To the top of the hinder-ſheat there is faſtened a ſhort handle by a wooden pin. Parallel to the hinder-ſheat there runs up a piece of wood of much the ſame form, called the drock; and to this is faſtened another horizontal piece, called the ground-wriſt: theſe are all on the right hand ſide of the *plough*, and parallel with the fore-ſheat. There runs another piece of much the ſame form with it, on the right hand; and the bottom of this is the earth-board. The long handle of this, which reaches as far that of the ſheat, is faſtened to the drock by a pin, the other end of which goes into the beam. Near the lower end of the fore-ſheat, there are two flat pieces of iron, which paſs from the two ſides of it up to the beam; and being let through it, are faſtened to the upper part by ſcrews and pins. Theſe keep the ſheat in its place.

The ſtructure of the four-coultered *plough* is different, in ſome reſpects from this, tho' in general founded on it. Its beam is ten foot long, whereas that of the common *plough* is but eight. The beam is ſtrait in the common *plough*, but in this it is arched in one fourth part of its length. near the *plough*-head. At the diſtance of three feet two inches from the end of the beam at the *plough*-tail, the firſt coulter, or that next the ſhare, is let through; and at thirteen inches from this, a ſecond coulter is let through: a third at the ſame diſtance from that; and, finally, the fourth at the ſame diſtance from the third, that is thirteen inches.

The crookedneſs of the upper part of the beam in this *plough* is contrived to avoid the too great length of the three foremoſt coulters, which would be too much, if the beam was ſtrait all the way; and they would be apt to bend and be diſplaced, unleſs they were vaſtly heavy and clumſy. Aſh is the beſt wood to make the beam of, it being ſufficiently ſtrong, and yet light.

The ſheat in this *plough* is to be ſeven inches broad. The fixing of the ſhare in this, as well as in the common *plough*, is the niceſt part, and requires the utmoſt art of the maker; for the well going of the *plough* wholly depends upon the placing of this. Suppoſing the axis of the beam, and the left ſide of the ſhare, to be both horizontal, they muſt never be ſet parallel to each other; for if they are, the tail of the ſhare bearing againſt the trench as much as the point, would cauſe the point to incline to the right hand, and it would be carried out of the ground into the furrow. If the point of the ſhare ſhould be ſet ſo, that its ſide ſhould make an angle on the right ſide of the axis of the beam, this inconvenience would be much greater; and if its point ſhould incline much to the left, and make too large an angle on that ſide with the axis of the beam, the *plough* would run quite to the left hand; and if the holder, to prevent its running quite out of the ground, turns the upper part of his *plough* toward the left hand, the pin of the ſhare will riſe up, and cut the furrow diagonally, leaving it half *unploughed*. To avoid this and ſeveral other inconveniences, the ſtrait ſide of the ſhare muſt make an angle upon the left ſide of the beam; but that muſt be ſo very acute a one, that the tail of the ſhare may only preſs leſs againſt the ſide of the trench than the point does.

The great thing to be taken care of, is the placing the four coulters; for on this the ſucceſs of the whole depends. Theſe muſt be ſo ſet, that the four imaginary planes deſcribed by their four edges, as the *plough* moves forward, may be all parallel to each other, or very nearly ſo; for if any one of them ſhould be very much inclined to, or ſhould recede much from either of the other, then they would not enter the ground together. In order to the placing them thus, the beam muſt be carefully pierced in a proper manner. The ſecond coulter hole muſt be two inches and an half more on the right hand than the firſt; the third muſt be as much more to the right of the

ſecond,

fecond, and the fourth the fame meafure to the right hand of the third: and this two inches and an half muft be carefully meafured from the center of one hole to the center of the other. Each of thefe holes is a mortaife of an inch and quarter wide, and is three inches and an half long at the top, and three inches at the bottom. The two oppofite fides of this hole are parallel to the top and bottom, but the back is oblique, and determines the obliquity of the ftanding of the coulter, which is wedged tight up to the poll.

The coulter is two foot eight inches long, before it is worn; the handle takes up fixteen inches of this length, and is allowed thus long, that the coulter may be driven down as the point wears away. *Tull*'s Horfe-hoeing Hufbandry, p. 132, feq. See COULTER.

Trenching-PLOUGH. See the article TRENCHING.

PLOUGH-*bote*, in our old writers, a right of tenants to take wood to repair *ploughs*, carts, and harrows, and for making rakes, forks, &c.

PLOUGH-*head*, a name given by the farmers to the foremoft half of the *plough*, or that part containing the two wheels and their fpindle, the box, the crow-ftaves, the pillow, the wilds, the tow-chain and bridle chain, and the ftake: all which, fee under their feveral heads, and under the article PLOUGH. *Tull*'s Hufbandry.

PLOUGH-*tail* a name given by the farmers to that part of a *plough* which contains the beam, the coulter, or coulters, the fhare, the fheat and under-fheet, the earth-board and handles, as alfo the drock, the ground-wrifts, and the retches: all which fee under their feveral heads, and under the article PLOUGH. *Tull*'s Hufbandry.

PLUKNETIA, in botany, the name of a genus of plants defcribed by Plumier, and called by this name in honour of Pluknet, the great Englifh botanift

The characters are thefe: It produces male and female flowers on the fame plants. The male flowers have no cup, but are compofed of four expanded petals of an oval figure, and in the place of ftamina, there is placed in the center of the flower a fhort pyramidal hairy body. The female flowers have no cup, and the petals in thefe are difpofed as in the male. The germen of the piftillum is fquare. The ftyle is flender, very long, and crooked. The ftigma is peltated and divided into four parts. The fegments are obtufe and flat, and each has a remarkable fpot in the center. The fruit is a depreffed fquare capfule, hollowed at all the angles: it contains four bivalve cells: the feeds are fingle, roundifh, and compreffed, and bluntly pointed at one end.

Linnæus obferves, that this fructification is very fingular, and is very defirous that fome perfon fhould examine carefully the growing plant, fince Plumier, who was not over curious about the nicer parts of the fructification of plants, may have in fome fort mifrepresented this. *Plumier* 13. *Linnæi* Gen. Pl. p. 517.

PLUM-*tree*, *prunus*, in botany. See PRUNUS.

All the fpecies of *plums* have within their fruit a hard ftone, within which there is contained a foft and tender kernel: this kernel contains the feminal plant, from which would be produced another tree of the fame kind, if it were fet in the ground; and it is very natural to fuppofe, that the only ufe of the thick ftone or hufk of this, was only to preferve its tender fubftance from rotting too foon in the earth, and to give it a proper time for developing its parts, to preferve its natural oilynefs during that time, and to furnifh from its own fubftance a proper nourifhment to the growing plant; for obfervation fhews, that it finally breaks into a very fine powder.

There has not been found any fpecies of *plum* which had not its kernel contained in a ftony coat of this kind, from whatever grafts they have been propagated; nor is there any art known by which the kernel of this fort of fruit can, while growing, be deprived of its coat.

Mr Marchand, however, in the year 1735, fhewed before the academy of fciences at Paris, certain *plums*, whofe kernels had no ftone or fhell round them; and found that they grew upon a tree which never had produced any others, and which had been known to produce fuch for twenty years. The kernel in thefe was covered with a reddifh fkin, which was rough to the touch; and within that, with another which was thinner and white. The kernel had nothing particular in it, except that it carried on one fide of its outer furface, and that always in the fame place, a little ftony prominence, more or lefs dented on its convex part: this is ufually a twelfth of an inch broad, and two thirds of an inch long, and has no other appearance but that of a diftempered part of the kernel, only that all the kernels have it.

The thick wrinkled fkin which furrounds the kernel, feems in this cafe to fupply the place of the ftone or hard fhell; and in this alfo it refembles it, that the pulp of the fruit parts eafily and readily from it; and the hard oblong body, which is placed on one fide of the kernel, is by no means proper for this purpofe. Mem. Acad. Scienc. Par. 1735.

All the forts of *plums* are propagated by budding, or grafting them upon ftocks of the mufcle-*plum*, the white pear-*plum*, the St. Julian, or the bonum magnum. See the article INOCULATING.

Budding is much properer than grafting for thefe trees, as they are apt to throw out a great deal of gum from the wound: and the trees fhould be no more than one year's growth from the bud, when they are tranfplanted; for if they are more they feldom fucceed well, being very fubject to canker; and if they efcape that, they ufually produce only two or three luxuriant branches. The whole management of planting and pruning them is the fame with that of peaches. See the article PEACH.

If the walls againft which they are planted are low, they fhould be fet eighteen feet afunder; if they are higher, then fourteen or fixteen.

Plums fhould have a middling foil, for they feldom fucceed well either in too moift or two dry a one; and when planted againft walls, fhould have an eaft or a fouth-eaft profpect. If they have one at full fouth, they are apt to fhrivel up, and mealy.

Plums in general fucceed very well with proper care on efpaliers; they will alfo bear very well as ftandards, but the fruit will not be fo well tafted. *Plums* do not only produce their fruit on the laft year's wood, but alfo on fpurs that come out of the wood of two or three years old. It is a common error to be too free with the knife in the winter-pruning, cutting off the extremities of all the branches; the confequence of which is, that there are an over quantity of young fhoots produced, and the fruit is fmall and poor. *Miller*'s Gard. Dict.

PLUMBAGO, *leadwort*, in botany, the name of a genus of plants, the characters of which are thefe: the flower confifts of one leaf, and is of a funnel-fhape, and divided into fegments at the edge. The cup is tubular, and from it arifes a piftil, which is fixed like a nail to the lower part of the flower, and afterwards ripens into an oblong pointed feed, which remains in the cup to ripen.

The fpecies of *plumbago*, enumerated by Mr. Tournefort, are thefe: 1. The ordinary *plumbago*, called by fome *lepidium* and *dentillaria*. 2. The white flowered *plumbago*. 3. The American *plumbago*, with a large beet-like leaf. 4. The prickly climbing American *plumbago*, with a fmaller beet-like leaf. *Tourn.* Inft. p. 140.

PLUMBAGO, in the hiftory of the gems, a word ufed by the Roman authors to exprefs a blemifh common to their worfe kinds, and greatly debafing their value. It was a fort of bluifh or blackifh deadnefs in the ftone, which mixed itfelf with the other colour, be that what it would, and rendered it dull and dead. The emerald was of all the other gems the moft fubject to this fault; and in this cafe, its fine green colour was always rendered cloudy and bluifh; and in fome lights the ftone appeared of a dufky greyifh blue, with no green at all in it. The Bactrian emeralds, which were in great efteem with the antients, were often fubject to this imperfection; and thofe of Cyprus, taken out of the coppermines, tho' fubject to many other imperfections, were ufually quite free from this.

PLUMBAGO, in mineralogy, a name given by many authors to a fort of foffil, having very much the appearance of a lead-ore, but not fuch in reality.

It is called alfo *galena*, *blende*, and *mock-lead*. It is ufually of a plated texture, and dark blackifh blue colour, like the lead-ores; but on trial yields no metal. See BLACK-*lead*.

PLUMBATA, among the antients, a kind of fcourge, the thongs of which were armed with leads. *Pitifc.* in voc.

PLUMBATÆ likewife fignified leaden balls, ufed by foldiers to annoy the enemy with; whence the foldiers were called *martiobarbuli*. *Pitifc.* in voc.

PLUMBUM (*Cycl.*)—PLUMBUM *nativum*, *native lead*. It is pretended by fome, that the famous *lead*-mineral, found near Freyung, in the Upper Palatinate, is *native lead*: but this is an error; we have an account of it in the philofophical tranfactions, which does not give any ground for this thought. All that is there faid of it, is, that it was at that time much efteemed among the affayers of metals, as containing no mixture of any other metal with the *lead*: this might well recommend it to them, as faving much confufion, or much trouble in feparating its heterogene contents; but it is faid exprefly there, that it is an ore, not a *native* metal: there being two kinds of it, one a chryftalline ftone, almoft all pure *lead*; the other not fo rich, but of a more rough and coarfe texture. Neither of thefe could be *native lead*; and it is remarkable, that they had lefs appearance of being fo than many of our common ores. Phil. Tranf Nº. 3. See the article LEAD.

PLUMBUM *uftum*. See LEAD, *Cycl.* and *Suppl.*

PLUMERIA, in botany, the name of a genus of plants, the characters of which are thefe: the flower confifts of one leaf, and is of the funnel-fhaped kind, and divided into feveral fegments at the edges. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. This finally becomes a podded fruit, ufually double; and when ripe, opening in the middle, and difcharging a number of oblong foliated feeds, which were placed like fcales over one another in the feed-veffel, and affixed to a placenta.

The fpecies of *plumeria*, enumerated by Mr. Tournefort, are thefe: 1. The *plumeria* with a rofe-coloured and very fweet flower. 2. The fnow-white-flowered *plumeria*, with long, narrow, and pointed leaves. 3. The *plumeria* with fnow-white flowers, and fhort obtufe leaves. *Tourn.* Inft. p. 659.

PLUMMER's *Æthiops.* This medicine is compofed of the fulphur auratum antimonii and calomel, commonly in equal parts; but this may be varied occafionally, according to the phyfician's difcretion. Thefe two powders muft be well levigated together, by which the bright red colour of the fulphur is changed into a dufky brown. We refer to the Medical Effays of Edinburgh, for the dofe, regimen to be obferved, and effects of this medicine; as alfo for the manner of preparing the fulphur of antimony according to Angelus Sala, which is faid to be preferable to the common method. See Med. Eff. Edinb abridg Vol. I. p. 205. and feq.

This medicine has been found greatly beneficial in cutaneous eruptions, in venereal infections, and in gleets remaining after the cure of a gonorrhœa. It operates by carrying off the excrements of diftempers by infenfible perfpiration or fweat It has alfo been found fuccefsful in obftinate glandular fwellings See Med. Eff. abrid ibid. and alfo Vol. II. p. 433.

PLUMMING, among miners, a term ufed to exprefs the ufing a mine dial, in order to know the exact place of the work where to fink down an air fhaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

It is performed in this manner: A fkilful perfon with an affiftant, and with pen, ink, and paper, and a long line and a fun dial, after his guefs of the place above ground defcends into the adit or work, and there faftens one end of the line to fome fixed thing in it, then the incited needle is let to reft, and the exact point where it refts is marked with a pen: he then goes on farther in the line ftill faftened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwife; and then letting down the dial again, he there likewife notes down that point at which the needle ftands in this fecond pofition. In this manner he proceeds from turning to turning, marking down the points, and marking the line till he comes to the intended place; this done, he afcends and begins to work on the furface of the earth, what he did in the adit, bringing the firft knot in the line to fuch a place where the mark of the place of the needle will again anfwer its pointing, and continues this till he comes to the defired place above ground, which is certain to be perpendicularly over the part of the mine into which the air fhaft is to be funk.

PLUMOSE *antennæ*, in natural hiftory, a term ufed to exprefs the *antennæ*, or horns of certain moths and butterflies, which are formed in the manner of feathers, being compofed of a ftem and fibres, iffuing on each fide from it: thefe are jointed and moveable any way, and even the fmall fibres, at their fides, are jointed at their bottom, and are moveable, but they move all together. *Reaumur's* Hift. of Infects. See the article FEELERS.

PLUNGE, in the manege. See the article ESTRAPADE.

PLURIES, a writ that iffues in the third place after two former writs have been difobeyed; for firft goes out the original writ or *capias*, which if it has not effect, then iffues the *alias*; and if that alfo fails, then the *pluries*. Old Nat. Br.33.

It is ufed in proceedings to outlawry, and in great diverfity of cafes. *Tabl. Reg. Writs. Blount, Cowel.*

PLUVIALIS, in zoology, the name by which Latin authors call the *plover*, a bird of which there are two kinds, the green and the grey.

The *green plover* is fomewhat larger than the lapwing, and is all over, on the upper parts, of a blackifh colour, variegated with very numerous fpots of a yellowifh green; its breaft is of a mixed brownifh and yellowifh green, and its belly is white: this is very much efteemed at table.

The *grey plover* is of the fame fize with the green, and is, on the upper parts, of a black colour, variegated with a pale greyifh green; and its breaft, belly, and thighs, are white. This is very common in Italy, as well as in England, and is efteemed nearly equal to the green at table. *Ray's* Ornithology, p 229.

PLUVIALIS *major*, in zoology, a name given by fome authors to the *limofa*, a bird in fome refpects refembling our redfhank, but larger and longer legg'd. *Aldrovand.* l. 20. c. 66. See the article LIMOSA.

This bird is alfo called the *glottis* and *totanas*.

PLUVIALIS *levis*, in zoology, a name given by many to the common green *wood-pecker*, the *picus viridis* of authors, called alfo in Englifh the *rain-fowl*, from an obfervation of its always being moft clamorous when rain is coming on. *Ray's* Ornithology, p. 93.

PLYMOUTH *marble*, among our artificers, a term ufed for a fort of *marble* dug in great plenty about Plymouth, and in fome other parts of Devonfhire, where it lies in very thick ftrata, and whence it is brought in large quantities to us; and when wrought looks little lefs beautiful than fome of the Italian *marbles*.

It is very hard and firm, and of a beautiful texture; its ground is a bluifh white, and its variegations are principally a pale red, and in fmaller quantities brown and yellow: thefe lie in very orderly beds, and often there is a very agreeable glow of a faint red diffufed thro' the whole fubftance. It is remarkably even in its whole ftructure, and is therefore capable of a more than ordinarily elegant polifh.

PLYNTERIA, πλυντήρια, in antiquity, a feftival in honour of Aglaurus, the daughter of king Cecrops, or rather of Minerva, who had from that lady the name of Aglaurus. For the ceremonies obferved at this folemnity, fee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 425.

PNEUMATODES, a word ufed by Hippocrates to exprefs a perfon who fetches his breath fhort and quick; and fometimes for one who has his belly or ilia much diftended by flatulencies. *Pneumatias* is alfo ufed in the fame double fenfe.

PNEUMATOMPHALOS, a word ufed by Hippocrates to exprefs a perfon who has a windy or flatulent rupture of the navel.

PNEUMONANTHE, in botany, a name given by many botanical writers to a fpecies of *gentiana*, called alfo by fome the *calathian* violet. See the article GENTIANA.

PNEUMONICS, in medicine, a term ufed for fuch things as are good for the lungs.

PNIGITIS *terra*, in the materia medica of the antients, a name given at different periods of time, to two different fpecies of earth; the *terra pnigitis* of Diofcorides and Pliny, being a grey marle, and the *pnigitis* of Galen a black clay.

The laft of thefe is a very valuable aftringent, and is found in many parts of this kingdom, particularly in the neighbourhood of London, and well deferves to be introduced into the practice of phyfic. *Hill's* Hift. of Foff. p. 35.

PNIGMOS, in medicine, any kind of fuffocation, from whatever caufe; it is very often ufed to exprefs that of hyfteric fits in women.

PNIX, a word ufed by phyficians to exprefs the fuffocation from hyfteric fits, or any other caufe.

POA, in the Linnæan fyftem of botany, the name of a diftinct genus of plants of the grafs kind, the characters of which are, That the calyx is a glume compofed of two valves, containing feveral flowers difpofed in a two-rowed oval, or oblong fpike; the valves oval and pointed, but without awns. The flower is compofed of two oval and pointed valves; thefe are hollowed, compreffed, a little longer than the valves of the cup, and without beards or awns; the ftamina are three capillary filaments; the antheræ are fplit at their ends; the germen of the piftillum is roundifh; the ftyles are two, reflex and hairy; the ftigmata are hairy alfo; the flower adheres clofely to the feed, and does not open to let it out; the feed is fingle, oblong, and pointed at both ends, and fomewhat flatted. *Linnæi* Genera Plant. p. 20.

POAKE-*root*, in Virginia, is ufed to denote the folanum bacciferum. The Indians ufe it for a purge, tho' commonly deemed a poifon. Phil. Tranf. N° 454. Sect. 1.

POCHARD, in zoology, the name of a fpecies of wild duck, called by fome the *penelops* and *rothals*, and by many in Englifh the red-headed *widgeon*.

It is larger than the common *widgeon*, and is fhorter and thicker bodied. The back and wings are grey, and beautifully variegated with grey and black ftreaks. The lower part of the neck, as alfo the rump, are black, but the whole head, and a great part of the neck, are reddifh; the throat is white, variegated with yellow; and the breaft and belly fomewhat brown: but the great diftinction of this bird from all the other ducks is, that the wings are all of the fame colour without variegation. *Ray's* Ornithol. p. 288.

POCKET *(Cycl.)*—POCKET, in the wool trade, a word ufed to exprefs a large fort of bag, in which wool is packed up to be fent from one part of the kingdom to another.

The *pocket* contains ufually twenty-five hundred weight of wool.

POCKET *inftruments*, in furgery, are fuch as a furgeon ought always to have in readinefs, and may conveniently carry about him in a proper cafe: thefe are two lancets of different fizes; the one proper to open abfceffes, the other fmaller, for bleeding; a pair of ftrait fciffars, ufeful on many occafions; a pair of crooked fciffars, proper to be ufed in dividing fiftulæ, and in feveral other cafes; a pair of forceps with teeth at one end, to remove dreffings, and upon occafion to extract fplinters or thorns; thefe are alfo ferviceable to the furgeon in his anatomical exercifes; they are commonly made of fteel, but thofe of filver are much neater; a razor; a ftrait incifion knife; a crooked incifion knife; a ftrait double-edged incifion knife; a probe with one end broad and thin, proper for difcovering a fiffure in the cranium, and of many other ufes; and the other end rounded, to examine the depth and fituation of wounds and ulcers. The neateft probes are made of filver, tho' they are frequently made alfo of fteel, ivory, or whalebone; a grooved probe or director, to direct the edge of the knife or fciffars in opening finufes or fiftulæ; that by this means the fubjacent veffels, nerves, and tendons, may remain unhurt. The upper end of this inftrument, fometimes, is ornamented, and ferves only for a handle; fometimes it is made in form of a fpoon, to contain powder to fprinkle upon wounds or ulcers; fometimes alfo this is made forked at the end, to divide the frænum of the tongue; a fpatula to deprefs the tongue, in order to examine the ftate of the tonfils, uvula, and fauces, when they are affected with any diforders; it is alfo ufed to fufpend the tongue when the frænum is to be divided; for which purpofe it is to be made with

with a fiffure at its extremity, and fhould therefore rather be made of filver than of any other metal. Befide thefe, there fhould be an ordinary fpatula for fpreading plaifters, ointments, and cataplafms; and fometimes by means of their fulcated extremity they are of fervice in raifing up fractured bones of the cranium; feveral needles muft alfo be kept here, fome ftrait and others crooked, for the ftitching up of wounds, taking up of arteries, and many other ufes. *Heifter*'s Surg. p. 12.

POCKET *medicines*. See the article MEDICINE.

POCO *allegro*, in the Italian mufic, is not fo faft as *allegro*.

Poco *largo*, intimates to play or fing a little flow. See LARGO.

Poco-*meno allegro*, is ufed to fignify that the part it is joined to fhould be placed or fung in a little lefs gay manner than *allegro* requires.

Poco *prefto*, ferves to let us know that we ought to fing or play the part to which it is annexed, not quite fo quick as *prefto* requires it fhould.

POCUMMA, in botany, a name given by the people of Guinea, to a fpecies of plant which they ufe as an aftringent. Their manner of taking it is very fingular; for they put the leaves among their dough, and bake them into a mafs with the bread, and then eat the whole together in their food. Phil. Tranf. N° 232.

POD, among botanifts, a fpecies of *pericarpium*, confifting of two valves which open from the bafe to the point, and are feparated by a membranaceous partition, from which the feeds hang by a kind of funiculus umbilicalis. See PERICARPIUM.

PODAGRA, a fpecies of the gout. See the article GOUT.

PODAGRA *lini*, in botany, a name given by fome of the later Greek writers to *cufcuta*, or *dodder*, when found growing on the linum or flax. The Latins have called this *epilinum*, as they do the dodder growing on thyme *epithymum*; the earlier Greeks called this *linozoftes*. Where this dodder takes root in a field of flax, it generally occupies many plants; and where it twines round them it caufes protuberances and fwellings, and has therefore been refembled to the gout on that plant.

PODAGRARIA, in botany, a name given by many authors to the leffer wild *angelica*, called alfo *herba Gerardis*. *Parkin.* Theat. p. 943.

PODERIS, in antiquity, a robe hanging down to the feet; but it is chiefly ufed to exprefs a linnen garment, a furplice, a fhirt. The Jewifh priefts were covered with this kind of long furplices, during the time of their attendance in the temple; and this was the proper habit of their order. *Calmet*, Dict. Bibl.

The word is Greek ποδήρης, from πους, pes, and ἄρω, apto. Vid *Hederic*. Lex. man. Græc. in voc.

PODICEPS, in zoology, a name given by many to the feveral kinds of *colymbi*, or *divers*, as they are alfo called in Englifh *arfe foots*; from their legs being placed very backward on their bodies, by which means they have great advantages in fwimming and diving. *Ray*'s Ornithol. p. 256. See the article COLYMBUS.

PODISMUS, Ποδισμος, among the Greeks, a certain fpace, or number of feet laid out by furveyors; it was the fame with what the Romans called *pedatura*. *Pitifc.* in voc. See the article PEDATURA.

PODIUM, in the theatre of the antients, the wall that feparated the orcheftra from the fcene. Mem. de l'Acad. Vol. I. p. 190. See ORCHESTRA and SCENE, *Cycl.*

POEANOPSIA, Ποιανοψια, in antiquity, a name fometimes given to the feftival Pyanepfia. See PYANEPSIA, *Cycl.*

POENITENTES, in the church of Rome, a defignation given to heretics, who being admonifhed by the ecclefiaftical judge, have abjured their errors, and given fufficient fatisfaction to the bifhop or inquifition. Confifcation of goods is a punifhment common to all heretics; but if they confefs and abjure of their own accord, without being formally profecuted, this part of their punifhment is ufually remitted. *Hofm.* Lex. Univ. in voc. See INQUISITION, *Cycl.*

POGGE, or CATAPHRACTUS, in zoology, the name of a fmall fea-fifh, caught in the Englifh and fome other feas.

It feldom grows to more than five inches in length; its head is of a triangular figure, and flatted, and is very broad, and is furrounded at the fides with a number of tubercles; the forepart toward the mouth has a number of extremely fine hairs, and the hinder part armed with a number of prickles; the points of which are directed backwards. Its fnout is fhort, and armed with four points; the two anterior ones refembling a horned moon, and the others being prickles with their points turned backwards. The mouth is in the lower part of the head, and is of a femi-circular form, and has two beards at its angles, and a number of hairs under its chin.

The body of this fifh, near its head, is flatted and of an octangular form; near the tail it is hexangular, and is of a brownifh colour variegated with black fpots. It is covered all over with bony fcales, in the middle of which there rifes a crooked tumor; which being continued thro' the whole number, makes the body of an angular form: toward the tail it grows very flender. It has two fins at the gills, two more on the belly, and two on the back, all fpotted with black fpots; and its tail ends in a fmall rounded fin. It has no teeth, but very rough and rigid lips, and lives on fhrimps and other fuch food. It is a very well tafted fifh.

It is caught not unfrequently on the coafts of Yorkfhire, and in great plenty in the mouth of the Elbe. *Wilughby*'s Hift. Pifc. p. 212. See Tab. of Fifh. N°. 30.

There is an American *cataphractus*, much refembling this, but having three angles on the hinder part of its head, one on each fide, and the third in the middle; and its upper chap elliptic, and its mouth a little prominent. Its head is covered with a brown and bony helmet; and its back, fides, and tail, with fcales of the fame colour, engraven with fmall parallel lines, and of a rhomboidal figure. Its belly is covered with a thin limber fkin. *Grew*'s Mufeum, Soc. Reg. p. 117.

POGO, a name by which the inhabitants of the Philippine iflands call their *quail*: it is very like our common quail, but fmaller.

POINCIANA, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the rofaceous kind, and is ufually compofed of five petals arranged in a circular form, and filled up in the middle with a larger number of crooked ftamina. The cup is divided into five leaves, the lower of which is crooked and imbricated: from this arifes the piftil, which finally becomes a hard pod of a flatted fhape, which when ripe opens into two parts, and contains a number of roundifh feeds divided from one another by a fort of membranaceous partitions.

There is only one known fpecies of the *poinciana*, which is the plant called by many *crifta pavonis*, and purple-flowered *acacia*. *Tourn.* Inft. p. 619.

POINSON, in the manege, is a little point or piece of fharp-pointed iron, fixed in a wooden handle, which the cavalier holds in his right hand when he means to prick a leaping horfe in the croupe, or beyond the end of the faddle, in order to make him yerk out behind.

POINT, (*Cycl.*) in geometry, is the termination of a line, and cannot be conceived to have parts. See SURFACE.

Hobbes defines a *point* to be a body whofe magnitude is not confidered. But his falfe notions of a *point*, line, and furface, have led him into many errors. Monfieur de Crouzas alfo has fuppofed a line to be compofed of *points*, in his geometry and comment on the analyfe des infiniment petits. This fuppofition only tends to confound learners. See *Jo. Bernoulli* Oper. Vol. IV. p. 161, feq.

Conjugate POINT, in geometry, is ufed for that *point* into which the *conjugate* oval, belonging to fome kinds of curves, vanifhes. *Mac Laur.* Algebr. p. 308.

POINT *of contrary flexure*. The *points of contrary flexure* and reflexion of curves, are ufually determined by fuppofing the fecond fluxion of the ordinate to be nothing or infinite, that is, $\ddot{y}=0$, or ∞, or $dd y=0$, or ∞. See *L'Hopital* Analyfe des Inf. petits.

But this rule is liable to feveral exceptions, as is fhewn very fully and clearly by Mr. Mac Laurin in his Treatife of Fluxions, B. i. ch. 9. and B. ii. ch. 5. art. 866.

The ordinate y paffes thro' a point of contrary flexure, when, the curve being continued on both fides of the ordinate, $\dot{y}$ is a maximum, or minimum. But this does not always happen when $\ddot{y}=0$, or ∞. Mr. Mac Laurin obferves, in general, that if $\ddot{y}$, $\dddot{y}$, $\ddddot{y}$, &c. vanifh, the number of thefe fluxions being odd, and the fluxion of the next order to them having a real and finite value; then y paffes thro' a *point* of contrary flexure; but if the number of thefe fluxions that vanifh be even, it cannot be faid to pafs thro' fuch a *point*; unlefs it fhould be allowed that a double infinitely fmall flexure can be formed at one *point*. Lib. cit. art. 866.

The curve being fuppofed to be continued from the ordinate y, on both fides, if $\dot{y}$ be infinite, the extremity of the ordinate is not therefore always a *point* of contrary flexure, as $\dot{y}$ is not always, in this cafe, a maximum, or minimum; and the curve may have its concavity turned the fame way on both fides of the ordinate. But thefe cafes may be diftinguifhed by comparing the figns of $\dot{y}$ on the different fides of the ordinate; for when thefe figns are different, the extremity of y meeting the curve is a *point* of contrary flexure.

The fuppofitions $\dot{y}=0$, or ∞, and of $\ddot{y}=0$, or ∞, ferve to direct us where we are to fearch for the maxima and minima, and for *points* of contrary flexure; but we are not always fure of finding them. For tho' an ordinate or fluxion that is pofitive, never becomes negative at once, but by increafing or decreafing gradually, yet after it has decreafed till it vanifh, it may thereafter increafe, continuing ftill pofitive; or after increafing till it becomes infinite, it may thereafter decreafe without changing its fign. See *Mac Laurin*, art. 262, 867.

POINT *of reflexion*, in geometry, is commonly ufed inftead of *point* of retrogradation, or retrogreffion. See the article RETROGRADATION, *Cycl.*

The general rule given by the Marquis de L'Hopital, for finding the *point of reflexion* in curves whofe ordinates are parallel, is the fame as that for finding the *point* of contrary flexure, and confifts in taking the fecond fluxion of the ordinate of the curve, and fuppofing it nothing or infinite: but this rule admits of many exceptions. See *Mac Laurin*'s Fluxions, B. i. ch. 9. and B. ii. ch. 5.

POINT, in the manege. A horfe is faid to make a *point*, when in working upon volts, he does not obferve the round regularly; but pulling a little out of his ordinary ground, makes a fort of angle or *point* by his circular tread This fault is prevented by haftening the hand. See HASTEN.

POINT is alfo ufed to denote the toes of a bow of afaddle. See the article BOW.

POISON (*Cycl.*)—We are apt to extend the fignification of this word very far, our common acceptation of it taking in every thing which, taken into the body, is capable of deftroying or highly injuring it. Hence the number of *poifons* is greatly increafed upon the world, and the abufe of many things, naturally wholefome or ufeful in food or phyfic, brings them into the clafs of hurtful things. This, however, brings great confufion into the writings or difcourfe of fuch who ufe it; and the fenfe of the word *poifon* becomes very vague and uncertain from it. A draught of cold water drank by a perfon while very hot, has been known to caufe inftant death; and according to this rule, cold water fhould therefore be a *poifon*.

Poifons are diftinguifhed by fome authors by feveral names, according to the different time and manner of their taking effect.

Some are called *venena terminata*. Thefe are fuch *poifons* as perform their fatal office, according to the opinion of the world, at certain ftated or determinate periods of time: thus, according to the quantity given, or the nature of the fpecies of *poifon*, a man muft be killed by it at the pleafure of the giver, either in an hour, a day, a week, a month, many months, or years; the *poifon* in this laft cafe operating like a chronical difeafe, and carrying off the patient by a very tedious train of fymptoms.

Others are called *venena temporanea*, temporary *poifons*. Thefe will kill a man by degrees, every minute of his life growing worfe and worfe, from the time of taking them to the final period; but this is not at any ftated or certain time.

Others are called *delibutoria venena*. Thefe are fuch as kill without being taken internally, and are furely fatal if rubbed upon the fkin, put into gloves, or the like.

As to the firft of thefe kinds, it is very much to be doubted whether there be in nature any fuch thing as a *venenum terminatum*, or a *poifon* which fhall kill at the fixed time at which the giver pleafes; fince all the known *poifons* are only relatively fuch, and depend for their effect on the peculiar ftate of the body: the different conftitutions of men muft therefore vary the period of time at which death muft happen from the taking the fame dofe. At leaft, if it be poffible to contrive a terminatory *poifon*, it muft require the fkill of the ableft phyfician to prepare it, fince he muft at once know the true ftate of the perfon's body who is to take it, and the exact power of the *poifon*, in its feveral dofes, on other bodies.

Much, therefore, is required in the phyfician who is to cure a perfon who has fwallowed *poifon*; fince the nature of the medicine, and the true knowledge of the ftate of the patient's body, are both neceffary in order to know what fymptoms to expect and guard againft.

Of the number of thofe *poifons* which take a long time to kill, and that different, according to their dofe and the habit of the perfon, are the venom of the toad and of the mad dog, whether the faliva he communicated immediately to the blood by a wound, or fwallowed with food or with the fpittle. The *poifon* of the tarantula is alfo of this number; and to thefe may be added, that of the fmall pox, meafles, and other difeafes of that kind, which is evidently long dormant in the body, till certain peculiar occafions and accidents call it forth to appear in its proper form. The *poifon* of the hectic fever is alfo by fome referred to this, it being accounted an alkaline virus, mixed with a vifcid matter. The *poifon* of the French pox, *lues venerea*, is alfo of this kind, and is efteemed highly acrid and alkaline. The *poifon* of cantharides, the acid ones of nitre, falt, vitriol, fulphur; the folutions or cryftals of gold, filver, and the other metals; and the precipitates of mercury, and the very fatal common arfenic. To thefe are added many others, and among them fome which act merely mechanically, by their numerous fharp points and edges; fuch as the powder of diamonds, glafs, and the like: and to this clafs belong many of the delibutory *poifons*. *Stentzel* Toxicolog

Of the temporaneous *poifons* many are taken under the common denominations of food and drink, and feem at firft to be of no injury; but by degrees they impair the conftitution, and bring on difeafes and death. Coffee, Tea, and all the fpirituous liquors are accounted of this kind.

We may perhaps afcribe the prodigious multiplicity of *poifons*, and that equally numerous tribe of antidotes treated of by the antients, to the love of the marvellous: however, it cannot be denied, that fome things are very fuddenly and ftrangely deftructive to animal life, and that in very fmall quantities Among the reft, there is a *poifon* made ufe of by the Indians, fome of which was fent over to the royal fociety by Mr. de la Condamine: Dr Brocklefby has given us fome accounts of its effects on cats, dogs, and birds, who were foon killed by it, only by fprinkling a few drops of the folution of this *poifon* on wounds made by a lancet. The doctor gave alfo two drachms of fugar to a bird, and fhortly afterwards poured a little of the folution into its mouth; but two drops had fcarce touched its tongue, before the creature was convulfed, and could with difficulty be laid down before all motion was taken away.

Hence it appears, that fugar is no fpecific againft this *poifon*, even when only taken at the mouth. Phil. Tranf. N°. 482, Sect. 12.

The negroes ufe a *poifon* of an extraordinary nature The dofe is very fmall, and it hath no ill tafte; fo that, mixed with meat or drink, it is not perceivable. It caufes divers fymptoms, and the effects are various, according as the dofe is large or fmall. It kills fometimes in very few hours, fometimes, it is faid, in fome months, and at others in fome years. The fymptoms are according to the quantity given; if great, it caufes evacuations upwards and downwards; of excrements firft, then of humours, and laftly of blood with fainting fits and fweatings. Death follows in fix or feven hours. The negroes turn white. Phil. Tranf. N°. 462. p 3.

The antidote to this *poifon* is the root of the fenfible weed, as it is commonly called, or *herba fenfitiva*, in decoction. Id. ibid. p 4.

Vegetable POISONS. It has been a general complaint, and indeed too juft a one, that the qualities of plants are much lefs ftudied than their external appearances; and the beft modern authors have contented themfelves with nicely characterifing plants according to their flowers and feeds, and afcertaining the proper names to each, without at all enquiring how they might be beneficial or hurtful to mankind, or diftinguifhing whether they were fafe medicines or deftructive *poifons*. Nor, indeed, is the inveftigating the virtues of plants, yet untried as medicines, any eafy tafk; fince neither chemical analyfes, nor experiments on brutes, nor even the tafte and fmell, and other fenfible qualities of plants, can ever certainly affure us what effects they will have on the human body.

Chemical analyfes alter the fubftance too much to give any certain knowledge; and the effects things have on one animal are no affurance of what they will do to another, as is familiar to us in a thoufand inftances. Bitter almonds, and many other things, wholly harmlefs to us, kill birds; and goats will eat the tithymals, to give them an appetite when they want it, while thofe very plants are fatal to fifhes, and very dangerous to man. The fenfible qualities as often deceive us, of which we fhall give many inftances; and what fome have obferved of the botanical characters of plants, telling us their virtues, or that all of the fame clafs poffefs the fame qualities, is the moft erroneous, and, if trufted to, might prove the moft fatal of all opinions; fince the known *poifons*, hemlock, phellandrium, and water-dropwort, with the *poifonous* juice, are all umbelliferous plants, and confequently of the fame family with fennel and angelica.

Nothing can, indeed, affure us with any degree of certainty of the virtues of plants, but experiments made on ourfelves; but few are to be found who wifh fo well to the public, as to venture their own lives for its fervice: and perhaps the honeft Gefner is the only man who ever carried thefe attempts to any degree, and he unhappily died a martyr to them, perifhing by the dofe he took of the fcorpion-rooted doronicum; the very root which has of late with us been fo fatal, by being accidentally mixed with our gentian.

What we learn of the vegetable *poifons* muft therefore be either by the confequences of the rafh prefcriptions or miftakes of the ignorant pretenders to medicine, or by the misfortune of thofe who have unwarily eaten them.

We have accounts in the memoirs of the academy of fciences of Paris, of many things of this kind. An apothecary, a very honeft man, but of no knowledge in botany, had made his extract of black hellebore from the roots of the chriftophoriana, or bane-berries, a plant always accounted a *poifon*, and a fingle berry of which is capable of killing feveral animals; yet fo far had the fire divefted the roots of their *poifonous* qualities, that twelve grains of this given as extract of hellebore, proved of no ill effect. Mem. Acad. Scienc. Par. 1739.

Another apothecary having learned, that hermodactyls were the roots of a fpecies of colchicum, dried the roots of the common colchicum, and fold them in its place; yet there is no knowledge of any ill effects from them.

The enquiry into things of this kind has its ufe, and that no fmall one; fince *poifons* often differ only in dofe from medicines, and many of the vegetables efteemed *poifonous*, may perhaps be found ufeful remedies, with proper management and in proper quantities.

The laurel-leaves are well known to afford a *poifonous* water in diftillation, yet it is as well known that they have been long ufed in cookery, to give a tafte like that of bitter almonds to creams &c. and that without any ill effect. The rofe-bay, or oleander, is well known to be a *poifon* to goats, yet is taken by the country-men of ftrong and robuft habits as a purge, and that with very good fuccefs. Nay, opium, one of the greateft of all medicines, if it had firft been difcovered by perfons taking over-dofes of it, and dying by it, as they naturally muft have done, might very naturally have been recorded to us as a very fatal *poifon*.

The plumbago, or dentillaria of Rondeletius, is fo violent a cauftic, that a poor girl who once anointed herfelf with it, to

cure her of the itch, was flead alive by it; yet this properly managed, and infufed in oils, has proved one of the greateft of all remedies for cancers.

The fhrub ufed in dying, and called by the French *redoul*, by fome authors *coriaria*. and by others the myrtle-leaved *rhus*, is generally known to to the world only as a drug ufeful in the dreffing of leather; but Pliny, and fome other old writers, have given it the character of an ufeful external medicine, and a remedy againft *poifons*; yet with all this inattention of the moderns, and all the praifes of the antients, this plant is truly a very terrible *poifon*. The grown cattle refufe to feed upon it, but the young lambs and kids often eat of it in thofe parts of Europe where it is common; and if they eat the full-grown leaves, they are killed by it; if the young fhoots only, which is more ufually the cafe, they are then only affected with fpafms and a fort of drunkennefs, of which, after a few hours, they recover. Nor is this fingular to this *poifonous* plant, fince it is well known, that many plants, of very improper kinds for food, are yet eaten in their young fhoots: and Linnæus has recorded it of the Laplanders, that they even eat the young fhoots of the *poifonous* blue aconite, or wolf's bane; and even in France they eat the firft fhoots of the clematitis, or flammula repens, the full-grown leaves of which are of fo acrid a nature, that they ferve the beggars to eat ulcers in their arms and legs, to give them a pretended title to charity.

The *redoul* is not only a *poifon* to animals, but its fatal effects have been feen on the human fpecies. A girl in France, where it is very common, gathering its fruit among blackberries, eat of them, and died epileptic, in fpite of all the affiftance that could be given her: and another inftance is given from the Hotel Dieu at Paris, where an unhappy traveller, a robuft man, was brought in epileptic, and died fo; tho' the caufe was not known, except by a vomit which was given him bringing up fome of the berries of this pernicious plant, and fome more of them having been found in his ftomach when diffected. Mem. Acad. Scienc. Par. 1739.

POISON-*wood*, in botany. See TOXICODENDRON.

POLA, in zoology, the name of a flat fifh, fomething refembling the foal; but fhorter and fmaller, commonly called *cynogloffus* and *linguatula*. See CYNOGLOSSUS.

It is caught in the Mediterranean, and fold in Rome and Venice for the table. *Bellon.* de Aquat. Vol. I. p. 37.

POLAEDRASTYLA, in natural hiftory, the name of a genus of cryftals. The word is derived from the Greek πολὺς, many, ἕδρα, fides, the privative particle α, not, and στύλος, a column; and expreffes a cryftal compofed of many planes and having no column.

The bodies of this genus are cryftals compofed of two octangular pyramids, joined bafe to bafe, and confequently the whole body confifting of fixteen planes. Of this genus there are only two known fpecies: 1. A brown kind with fhort pyramids, found in confiderable plenty in Virginia on the fides of hills; and, 2. a colourlefs one, with longer pyramids. This has yet been found only in one place, which is the great mine at Goffelaer, in Saxony, and there ufually lies at great depths. *Hill*'s Hift. of Foff. p. 171.

POLE (*Cycl.*)—*Hop*-POLES, the upright pieces of wood that ferve for the hops to twift round and grow upon.

The number, length, and bignefs of the *poles* are to be regulated according to the bignefs of the hills, and their diftance, and the nature of the ground, and ftrength of the plants.

If the hills are wide, there muft be the more *poles*, fometimes four or five to a hill, or more than that; but if they ftand near, two may ferve for every hill. In hot, dry, and hungry ground, the *poles* fhould ftand nearer than in rich mellow land, where they are more fubject to grow grofs and heavy.

If the plants are ftrong, and the ground rich, the *poles* muft be both large and long, or elfe the crop will fuffer greatly: if the crop be poor, it is beft to have but few, and thofe fmall and fhort *poles*, otherwife the hop will eafily run itfelf out of heart, and the root will be impoverifhed.

The *poles* fhould never be made over long the firft year. The propereft wood for *hop-poles* is the afh or the alder, and if they have a fort of fork at the top, they will keep up the *hop* the better. The *poles* are to be difperfed between the hills, to be in readinefs; but they muft not be fet up till the plants begin to appear, that it may be known where they ought to be placed. This may be continued till the plants are a yard high, but it ought to be finifhed by that time, becaufe the plants will be ftunted or injured in their growth, if they have not fomething to fupport them when arrived at that heighth.

The *poles* muft be placed not in the hill, but near that part of it out of which each plant to be fupported grows. They muft be driven far enough into the ground, fo that they may rather break than be torn up. Their depth is to be judged by the nature of the ground, their own height, and their expofure to the wind. Let all the *poles* lean outward one from another, that they may feem to ftand at an equal diftance at the top, to prevent the choaking up the plants below; and they fhould always lean towards the fouth, that the fun may the better fhine in among them. A floping *pole* is always more ready to bear a quantity of *hops* than an upright one, and the fun fhines on more of the plants at once by means of it. It is always neceffary to keep fome fpare *poles*, by way of referve, to be ready in cafe of the others breaking; for in this cafe, the *hops* are foon fpoiled with lying on the ground. If a *pole* be over-burthened with *hops*, they may be unwound, and wrapped round a ftronger *pole* put in the place of the other.

The largeft fort of *hop-poles* fhould be twenty foot long, and nine inches in circumference, for hops at full growth; and they fhould be polled about fourteen days after the dreffing in of rich land. An acre of *hop* ground generally requires about three thoufand *poles*.

When the *hops* are grown to three foot high, they are to be conducted to fuch of the *poles* as are neareft, or have feweft *hops* on them; and they are to be wound about thefe *poles* according to the courfe of the fun, and tied to them loofely with fome rufhes, or with foft yarn: two or three ftrings are fufficient to each *pole*, and great care is to be taken that the young fhoots are not broken in the doing this; they are much more brittle in the morning than the heat of the day. During the months of April and May the plants are to be carefully attended, and kept turned round the *poles*; and when out of reach, a fork, ftick, or ladder are to be ufed to this purpofe.

About Midfummer they ufually leave running at length, and begin to branch; fuch as do not, fhould have the end broke off, to incline them to it, it being much to the advantage of the owner that they fhould branch out. From the middle of May to the end of fummer, the ground between the *poles* fhould be dug or turned up with a plough, to kill the weeds; and the earth about the hills raifed higher, to keep them moift. *Mortimer*'s Hufb. p. 177. See HOP.

POLEMARCHUS, Πολέμαρχος, among the Athenians, a magiftrate who had all the ftrangers and fojourners in Athens under his care, over whom he had the fame authority that the archon had over the citizens.

It was the duty of the *polemarchus* to offer a folemn facrifice to Enyalus, faid by fome to be the fame with Mars, but by others to have been only one of his attendants; and another to Diana, furnamed Αγροτέρα, in honour of the famous patriot Harmodius. It was alfo the bufinefs of the *polemarchus* to take care that the children of thofe who had loft their lives in their country's fervice, fhould have a competent maintenance out of the public treafury. *Potter*, Archæol. Græc. l. 1. c. 12. T. 1. p. 77.

POLEMONIUM, *polemony*, in botany, the name of a genus of plants, the characters of which are thefe: the flower confifts of a fingle leaf, and is of a rotated form, and divided into fegments at the edge. From the cup there arifes a piftil, which is fixed in the manner of a nail to the middle part of the flower, and finally becomes a roundifh fruit, or cafe, divided into three cells, which are full of oblong feeds.

The fpecies of *polemonium*, enumerated by Mr. Tournefort, are thefe: 1. The common blue flowered *polemonium*, called by fome *Greek-valerian*, with blue flowers. 2. The common white-flowered *polemonium*, or *Greek-valerian*, with white flowers. 3. The *polemonium* with variegated flowers, or *Greek-valerian*, with flowers ftriped with blue and white. *Tourn.* Inft. Bot. p. 146

POLETÆ, Πωληταὶ, among the Athenians, ten magiftrates, who together with three that had the care of the money allowed for fhews, had the power of letting out the tribute money, and other public revenues, and felling confifcated eftates; all which bargains were ratified in the name of their prefident. Befides this, it was their office to convict fuch as had not paid the tribute called Μετοίκιον, and fell them by auction. *Potter*, Arch. Græc. l. 1. c. 14. T. 1. p. 80.

POLGAHA, in botany, a name by which fome authors have called the cocoa-nut tree, or *palma Indica nucifera* of other writers. *Herm.* Muf. Zeyl. p. 50.

POLIA *lithargyrus*, a term ufed by Diofcorides to exprefs the white litharge, which we call litharge of filver.

The proper fenfe of the word *polia*, is hoary, or grey, and it very well expreffes the colour of this fubftance; but the commentators have not been fatisfied with this obvious meaning, but have made it *pelia*, and fome of them *ficelia*. See the article LITHARGE.

POLIEIA, Πολιεῖα, in antiquity, a folemnity of Thebes in honour of Apollo, furnamed πολιος, *i. e.* grey, becaufe he was reprefented in this city (contrary to the practice of all other places) with grey hairs. *Potter*, Archæol. T. 1. p. 426.

POLIIFOLIUM, in botany, the name of a genus of plants defcribed by Buxbaum, the characters of which are thefe: the flowers are monopetalous, of the bell-fafhioned globofe kind; the feed-veffel is divided into five parts, and contains a number of roundifh feeds; the leaves are like thofe of the poly-mountain, whence the name; the flowers refemble thofe of the arbutus, or ftrawberry-tree; and the fruit that of the ciftus.

The plant has been known among authors before, tho' ill-

 fpecies,

named and confounded with other genera; Ray has called it *fedum a but: fiore*. It properly belongs to the plants of the fhrub-kind, with dry fruits, and ought to be placed after the chamærhododendros, in the regular arrangements of plants.

Befide the common kind of this, there is an African one, the leaves of which are fhorter and rounder than thofe of this fpecies, and which may be called the fhort-leaved African fhrub *polyfolium*

POLIOPUS, in zoology, a name given by Aldrovand, and fome other authors, to the *grinetta*; a fmall bird of the moor-hen kind. See GRINETTA.

POLISHING (*Cycl.*)—POLISHING *of fhells*. This is an art of no long ftanding in the world, in its prefent perfection; and as the love of fea-fhells is become fo common among us, it may not be difagreeable to the reader to find fome inftructions in executing fo pleafing a method of adding to their natural beauty, and the rules for which are at prefent fo little known, tho' the effect of them be fo much efteemed.

Among the immenfe variety of fhells, which we are acquainted with, fome are taken up out of the fea, or found on its fhores in all their perfection and beauty; their colours being all fpread by nature upon the furface, and their natural *polifh* fuperior to any thing that art could give. Where nature is in herfelf thus perfect, it were madnefs to attempt to add any thing to her charms; but in others, where the beauties are latent, and covered with a coarfer outer fkin, art is to be called in, and the outer veil being taken off, all the internal beauties appear

Among the fhells which are found naturally *polifhed*, are the porcelanes, the caffanders, the dolia, or conchæ globofæ, the buccinums, the cornets, and the cylinders, or as they are generally, tho' improperly called, the rhombi; excepting only two or three, as the tiara, the plume, and the buttertub-rhombus; where there is an unpromifing film on the furface, biding a very great fhare of beauty within.

Tho' the generality of the fhells of thefe genera are taken out of the fea in all their beauty, and in their utmoft natural *polifh*, there are feveral other genera in which all, or moft of the fpecies are taken up naturally rough and foul, and covered with an epidermis, or coarfe outer fkin, which is in many rough and downy, or hairy. The tellinæ, the mufcles, the cochleæ, and many others are of this kind. The more nice collectors, as naturalifts, infift upon having all their fhells in their native and genuine appearance, as they are found when living at fea; but the ladies who make collections, hate the difagreeable outfides, and will have all fuch *polifhed*: it would be very adviseable, however, for both kinds of collectors to have the fame fhells in different fpecimens, both rough and *polifhed*; the naturalift would by this means, befide knowing the outfide of the fhell, be better acquainted with its internal characters than he otherwife could be, and the lady would have a pleafure in comparing the beauties of the fhell in its wrought ftate, to its coarfe appearance as nature gives it. How many elegancies in this part of the creation muft be wholly loft to us, if it were not for the affiftance of an art of this kind! many fhells in their native ftate are like rough diamonds, and we can form no juft idea of their beauties till they have been *polifhed* and wrought into form.

Tho' the art of *polifhing* fhells is a very valuable one, yet it is very dangerous to the fhells; for without the utmoft care the means ufed to *polifh* and beautify a fhell will often wholly deftroy it. When a fhell is to be *polifhed*, the firft thing to be examined is, whether it have naturally a fmooth furface, or be covered with tubercles or prominences.

A fhell which has a fmooth furface and a natural dull *polifh*, need only be rubbed with the hand, or with a piece of chamoy leather, with fome tripoli or fine rottenftone, and it will become of a perfectly bright and fine *polifh*. Emery is not to be ufed on this occafion, becaufe it wears away too much of the fhell. This operation requires the hand of an experienced perfon, that knows how fuperficial the work muft be, and where he is to ftop; for in many of thefe fhells the lines are only on the furface, and the wearing away ever fo little of the fhell defaces them. A fhell that is rough, foul, and crufty, or covered with a tartarous coat, muft be left a whole day fteeping in hot water: when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a ftick, or with the blade of a knife, in order to get off the coat. After this, it may be dipped in diluted aqua fortis, fpirit of falt, or any other acid; and after remaining a few moments in it, be again plunged into comm n water. This will greatly add to the fpeed of the work. After this it is to be well rubbed with linnen cloths, impregnated with common foap; and when by thefe feveral means it is made perfectly clean, the *polifhing* is to be finifhed with fine emery and a hair brufh. If after this the fhell when dry appears not to have fo good a *polifh* as was defired, it muft be rubbed over with a folution of gum arabic; and this will add greatly to its glofs, without doing it any fort of injury. The gum-water muft not be too thick, and then it gives no fenfible coat, only heightening the colours. The white of an egg anfwers this purpofe alfo very well; but it is fubject to turn yellow. If the fhell has an epidermis, which will by no means admit the *polifhing* of it, it is to be dipped feveral times in diluted aqua fortis, that this may be eaten off; and then the fhell is to be *polifhed* in the ufual way with putty, fine emery, or tripoli, on the hair of a fine brufh. When it is only a pellicle that hides the colours, the fhells muft be fteeped in hot water, and after that the fkin worked off by degrees with an old file. This is the cafe with feveral of the cylinders, which have not the natural *polifh* of the reft.

When a fhell is covered with a thick and fatty epidermis, as is the cafe with feveral of the mufcles and tellinæ: in this cafe aqua fortis will do no fervice, as it will not touch the fkin; then a rough brufh and coarfe emery are to be ufed; and if this does not fucceed, feal-fkin, or as the workmen call it *fifh skin* and *pummice-ftone*, are to be taken in to affift.

When a fhell has a thick cruft, which will not give way to any of thefe means, the only way left is to plunge it feveral times into ftrong aqua fortis, till the ftubborn cruft is wholly eroded. The limpets, auris marina, the helmet-fhells, and feveral other fpecies are of this kind, and muft have this fort of management; but as the defign is to fhew the hidden beauties under the cruft, and not to deftroy the natural beauty and *polifh* of the infide of the fhell, the method of ufing the aqua fortis muft be this: A long piece of wax muft be provided, and one end of it made perfectly to cover the whole mouth of the fhell; the other end will then ferve as a handle, and the mouth being ftopped by the wax, the liquor cannot get in to the infide to fpoil it; then there muft be placed on a table, a veffel full of aqua fortis, and another full of common water.

The fhell is to be plunged into the aqua fortis; and after remaining a few minutes in it, is to be taken out and plunged into the common water. The progrefs the aqua fortis makes in eroding the furface is thus to be carefully obferved every time it is taken out: the point of the fhell, and any other tender parts, are to be covered with wax, to prevent the aqua fortis from eating them away; and if there be any worm-holes, they alfo muft be ftopped up with wax, otherwife the aqua fortis would foon eat thro' in thofe places. When the repeated dippings into the aqua fortis fhew that the coat is fufficiently eaten away, then the fhell is to be wrought carefully with fine emery and a brufh; and when it is *polifhed* as high as can be by this means, it muft be wiped clean and rubbed over with gum-water, or the white of an egg. In this fort of work the operator muft always have the caution to wear gloves, otherwife the leaft touch of the aqua fortis will burn the fingers, and turn them yellow; and often if it be not regarded, will eat off the fkin and the nails.

Thefe are the methods to be ufed with fhells, which require but a moderate quantity of the furface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper; this is called entirely fcaling a fhell. This is done by means of an horizontal wheel of lead or tin, impregnated with rough emery; and the fhell is wrought down in the fame manner in which ftones are wrought by the lapidary. Nothing is more difficult, however, than the performing this work with nicety: very often fhells are cut down too far by it, and wholly fpoiled; and to avoid this, a courfe vein muft be often left ftanding in fome place, and taken down afterwards with the file, when the cutting it down at the wheel would have fpoiled the adjacent parts.

After the fhell is thus cut down to a proper degree, it is to be *polifhed* with fine emery, tripoli, or rotten ftone, with a wooden wheel turned by the fame machine as the leaden one, or by the common method of working with the hand with the fame ingredients, when a fhell is full of tubercles, or protuberances, which muft be preferved. It is then impoffible to ufe the wheel; and if the common way of dipping into aqua fortis be attempted, the tubercles being harder than the reft of the fhell, will be eat thro' before the reft is fufficiently fcaled, and the fhell will be fpoiled: in this cafe induftry and patience are the only means of effecting a *polifh*. A camel's hair pencil muft be dipped in aqua fortis, and with this the intermediate parts of the fhell muft be wetted, leaving the protuberances dry: this is to be often repeated, and after a few moments the fhell is always to be plunged into water to ftop the erofion of the acid, which would otherwife eat too deep, and deftroy the beauty of the fhell. When this has fufficiently taken off the foulnefs of the fhell, it is to be *polifhed* with emery of the fineft kind, or with tripoli; by means of a fmall ftick, or the common *polifhing* ftone ufed by the goldfmiths may be ufed.

This is a very tedious and troublefome thing, efpecially when the echinated oyfters and murexes, and fome other fuch fhells are to be wrought; and what is worft of all is, that when all this pains has been taken, the bufinefs is not well done; for there ftill remain feveral places which could not be reached by any inftrument; fo that the fhell muft neceffarily be rubbed over with gum-water, or the white of an egg afterwards, in order to bring out the colours and give a glofs; in fome cafes it is even neceffary to give a coat of varnifh.

Thefe are the means ufed by artifts to brighten the colours, and add to the beauty of fhells; and the changes produced by

by *poliſhing* in this manner are ſo great, that the ſhell is often not to be known afterwards for the ſame it was; and hence we hear of new ſhells in the cabinets of collectors, which have no real exiſtence as ſeparate ſpecies, but are the *poliſhed* appearance of others well known. To caution the reader againſt errors of this kind, it may be proper to add the moſt remarkable ſpecies thus uſually altered.

The onyx-ſhell, which in its natural ſtate is of a ſimple pale brown, when it is wrought ſlightly, or *poliſhed* with juſt the ſuperficies taken off, is of a fine bright yellow; and when it is eat away deeper, it appears of a fine milk-white with the lower part bluiſh: it is in this ſtate that it is called the onyx-ſhell; and it is preſerved in many cabinets in its rough ſtate, and in its yellow appearance as different ſpecies of ſhells.

The violet ſhell, ſo common among the curious, is a ſpecies of porcelane, which does not appear in that elegance till it has been *poliſhed*; and the common auris marina ſhews itſelf in two or three different forms, as it is more or leſs deeply wrought. In its rough ſtate it is duſky and coarſe, of a pale brown on the outſide and pearly within; when it is eaten down a little way below the ſurface, it ſhews variegations of black and green, and when ſtill farther eroded it appears of a fine pearly hue within and without.

The nautilus, when it is *poliſhed* down, appears all over of a fine pearly colour, but when it is eaten away but to a ſmall depth, it appears of a fine yellowiſh colour with duſky hairs. The burgau, when entirely cleared of its coat, is of the moſt beautiful pearl-colour; but when only ſlightly eroded, it appears of a variegated mixture of green and red; whence it has been called the *parroquet*-ſhell. The common helmet-ſhell, when wrought, is of the colour of the fineſt agate; and the muſcles in general, tho' very plain ſhells, in their common appearance, become very beautiful when *poliſhed*, and ſhew large veins of the moſt elegant colours. The Perſian ſhell, in its natural ſtate, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and *poliſhed*, it appears of a grey colour with ſpots and veins of a very bright and highly *poliſhed* white. The limpets in general become very different when *poliſhed*, moſt of them ſhewing very elegant colours; among theſe the tortoiſe-ſhell-limpet is the principal; it does not appear at all of that colour or tranſparence till it has been wrought.

That elegant ſpecies of ſhell called the junquil-chama, which has deceived ſo many judges of theſe things into an opinion of its being a new ſpecies, is only a white *chama* with a reticulated ſurface; but when this is *poliſhed*, it loſes at once its reticular work and its colour, and becomes perfectly ſmooth and of a fine bright yellow: and the violet-coloured *chama* of New England, when worked down and *poliſhed*, is of a fine milk-white with a great number of blue veins diſpoſed like the variegations in agates.

The aſſe's ear-ſhell, when *poliſhed*, after working it down with the file, becomes extremely gloſſy, and obtains a fine roſe-colour all about the mouth. Theſe are ſome of the moſt frequent among an endleſs variety of changes wrought on ſhells by *poliſhing*; and we find there are many of the very greateſt beauties of this part of the creation which muſt have been loſt but for this method of ſearching deep in the ſubſtance of the ſhell for them.

The Dutch are very fond of ſhells, and are very nice in their manner of working them: they are under no reſtraint, however, in their works, but uſe the moſt violent methods, ſo as often to deſtroy all the beauty of the ſhell. They file them down on all ſides, and often take them to the wheel when it muſt deſtroy the very characters of the ſpecies; nor do they ſtop at this, but determined to have beauty at any rate, they are for improving upon nature, and frequently add ſome lines and colours with a pencil, afterwards covering them with a fine coat of varniſh; ſo that they ſeem the natural lineations of the ſhell: the Dutch cabinets are by this means made very beautiful, but they are by no means to be regarded as inſtructors in natural hiſtory. There are ſome artificers of this nation who have a way of colouring ſhells all over with a different tinge from that which nature gives them; and the curious are often deceived by theſe tricks into the purchaſing them as new ſpecies.

There is another kind of work beſtowed on certain ſpecies of ſhells, particularly the nautilus; this is the engraving on it lines and circles, and figures of ſtars, and other things: this is too obvious a work of art to ſuffer any one to ſuppoſe it natural. Bonani has figured ſeveral of theſe wrought ſhells at the end of his work, but it is miſerably throwing away labour to do them; the ſhells are ſpoiled as objects of natural hiſtory by it, and the engraving is ſeldom worth any thing. They are principally done in the Eaſt-Indies.

Shells are ſubject to ſeveral imperfections; ſome of theſe are natural, and others accidental: the natural ones are the effect of age, or ſickneſs in the fiſh. The greateſt miſchief happens to ſhells by the fiſh dying in them. The curious in theſe things pretend to be always able to diſtinguiſh a ſhell taken up with the fiſh alive, from one found on the ſhores: they call the firſt a living, the ſecond a dead ſhell, and ſay that the colours are always much the fainteſt in the dead ſhells. When the ſhells have lain long dead on the ſhores, they are ſubject to many injuries, of which the being eaten by ſea-worms is not the leaſt: age renders the fineſt ſhells livid or dead in their colours.

The fineſt ſhells are thoſe which are fiſhed up at ſea, not found on the ſhores. The other natural defects of ſhells are there having morbid cavities, or protuberances, in parts where there ſhould be none. When the ſhell is valuable theſe faults may be hid, and much added to the beauty of the ſpecimen, without at all injuring it as an object of natural hiſtory, which ſhould always be the great end of collecting theſe things. The cavities may be filled up with maſtic, diſſolved in ſpirit of wine, or with iſinglaſs; theſe ſubſtances muſt be either coloured to the tinge of the ſhell, or elſe a pencil dipped in water colours muſt finiſh them up to the reſemblance of the reſt, and then the whole ſhell being rubbed over with gum-water, or with the white of an egg, ſcarce any eye can perceive the artifice: the ſame ſubſtances may alſo be uſed to repair the battered edge of a ſhell, provided the pieces chipped off be not too large. And when the excreſcences of a ſhell are faulty, they are to be taken down with a fine file. If the lip of a ſhell be ſo battered that it will not admit of repairing by any cement, the whole muſt be filed down to an evenneſs, or ground on the wheel.

POLITICAL (*Cycl.*)—POLITICAL *arithmetic*. According to Mr. Kerſeboom's computation, the inhabitants of Holland and Weſtfriezeland, in the year 1738, amounted to 980000. He has given us a table of the particulars, exhibiting the number of people of all ages, living at the ſame time, from their birth to extreme old age. This table having the chances of mortality within the ages mentioned, he calls the table of contingency of life and death.

This table is calculated upon three principles: 1. On correct obſervations upon the tables of aſſignable annuities in Holland, which have been kept there for above 125 years; wherein the ages of the perſons dying are truly entered. 2. Upon a ſuppoſition that there are yearly born in the two provinces 28000 living children. 3. That the whole number of inhabitants, in any country, is to the number of births as 35 to 1. From this table it appears, 1. That more than half the number of people in the two provinces are above 27 years old. 2. That by the obſervations made in England, out of 35 children born, 18 of them are boys, and 17 girls: the inhabitants of Holland and Weſtfriezeland, conſiſt of 504000 males, and 476000 females, the ſum of which is 980000.

Here follows the table of contingency of life and death.

Of above 90 years old	500	
Of 90 to 86 incl.	2500	
85 — 81	6500	
80 — 76	13000	
75 — 71	20300	
70 — 66	27300	
65 — 61	34300	
60 — 56	40800	
55 — 51	47000	
50 — 46	53000	
45 — 41	57800	
40 — 36	62500	
35 — 31	67600	
30 — 27	58400	
	491500	ſum above 27 years old.
Of 26 — 21	94300	
20 — 16	83400	
15 — 11	87200	
10 — 6	91800	
5 to birth	131800	
	488500	ſum under 27 years old.
	491500	
	488500	
	980000	ſum of all the inhabitants.

Mr. Kerſeboom obſerves from the aſſignable annuities for lives before-mentioned, that females, one with another, live about three or four years longer than the ſame number of males.

He alſo thinks there is no reaſon to differ from the proportions aſſigned by Mr. King (in Davenant's eſſays) of the ſtate and condition of the inhabitants of England; which is, that for every 100000 inhabitants there is

Married men and women	34500
Widowers	1500
Widows	4500
Unmarried youth and children	45000
Servants	10500
Travellers, ſtrangers, *&c.*	4000
	100000

If

If this propofition be admitted, then the number of each fort in Holland and Weftfriezeland, will be as in the following table:

In the two provinces of Holl. and Weft.		Amfter.
Married men and women	338100	86156
Widowers	14700	4218
Widows	44100	13858
Unmarried youth and children	441000	93990
Servants	102900	28318
Travellers, ftrangers, &c.	39200	14460
Total	980000	241000

The mortality of the feveral quarters of the year.

Spring to fummer	307 dead.
Summer to the autumnal equinox	286
Autumn to winter	287
Winter to fpring	286

The mortality of the different months of the year obferved for 31 years, one with another.

Dead in	
January	102
February	88
March	95
April	77
May	112
June	100
July	92
Auguft	95
September	99
October	93
November	95
December	99

Hence it appears, that April is the leaft, and May the moft fatal Month in the year; their proportion of mortality being nearly as 2 to 3: and that of the four feafons of the year, moft deaths happen in the fpring; that is, from the vernal equinox to the fummer folftice.

Mr. Kerfeboom adds, that thefe provinces may raife 220000 men able to bear arms, and feveral other curious obfervations. His book is intitled, *Verhandeling tot een proeve, om te weeten de probable menigte des volks in de proventie van Holland en Weftfriezlandt.* Hage 1738. 4°.

POLITICAL *divifion of antient Egypt.* See NOME.

POLIUM, *poley-mountain*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf, and is of the labiated kind; but the place of the upper lip is fupplied by the ftamina. The under lip is divided into five fegments. The piftil arifes from the cup; it is fixed in the manner of a nail to the hinder part of the flower, and furrounded by four embryos, which afterwards become fo many feeds remaining in the flower-cup, which ferve them as a capfule. The flowers of this plant are collected into heads, and grow at the tops of the ftalks.

The fpecies of *poley-mountain*, enumerated by Mr. Tournefort, are thefe: 1. The lavender-leaved *poley*. 2. The narrower-leaved lavender-*poley*. 3. The yellow-flowered common *poley*. 4. The common white-flowered *poley*. 5. The narrower-leaved longer-headed white-flowered *poley*. 6. The creeping *poley*. 7. The French erect fea-*poley*. 8. The procumbent Venetian fea-*poley*. 9. The purple-flowered tender woolly-leaved *poley*. 10. The white tender procumbent *poley*. 11. The ground ivy-leaved tender procumbent Pyrenean *poley*. 12. The purple-flowered, germander-leaved Spanifh *poley*. 13. The fmoother procumbent Portugal *poley*, with purple ftalks and white flowers. 14. The purple-flowered fhort-headed broad-leaved Spanifh *poley*. 15. The great white Spanifh *poley*. 16. The great yellow Spanifh *poley*. 17. The white-flowered rofemary-leaved fea-*poley* of Spain. 18. The red-flowered fhrubby fea-*poley* of Spain, with rofemary leaves. 19. The red-flowered, rofemary-leaved, dwarf mountain-*poley* of Spain. 20. The yellow-flowered procumbent Spanifh *poley*. 21. The longer-headed Spanifh *poley*, with variegated flowers. 22. The white-flowered, fhort-headed, narrow-leaved erect *poley*. 23. The white-flowered Spanifh *poley*, with hoary leaves, refembling thofe of toad-flax. 24. The white-flowered fhorter-leaved Spanifh *poley*, with toad-flax leaves. 25. The red-flowered dwarf-*poley-mountain*, with narrow green leaves and hoary ftalks. 26. The little narrow-leaved erect *poley*, with greenifh white ferrated leaves 27. The leffer procumbent white narrow-leaved *poley*, with ferrated leaves. 28. The red-flowered erect fmall *poley*, with fhort, narrow, and thick cluftered leaves. 29. The procumbent red-flowered cudweed-like mountain-*poley*, with divided leaves. 30. The white-flowered cudweed-like fea-*poley*. 31. The whole-leaved white Spanifh *poley*. 32. The larger erect, broad-leaved white *poley*, with ferrated leaves. 33. The great procumbent broad-leaved *poley*, with ferrated leaves. 34. The leffer procumbent broad-leaved white *poley*, with ferrated leaves. 35. The yellow Spanifh *poley*, with marjoram-like leaves. 36. The purple-flowered ferpyllum-leaved Spanifh *poley*. 37. The purple-fpiked thyme-leaved Spanifh *poley*. *Tourn* Inft. p. 206.

POLLACK, in ichthyology, a name which we give to two different fifh of the afellus or gadus kind, with the different epithets of *raw* and *whiting*. The *raw-pollack* is the fame fpecies that in fome parts of England is called the cole-fifh, and is the afellus niger of authors. The other is called the *whiting-pollack*; and is the *afellus virefcens* of Willughby and others.

Both thefe fifh are, according to the new Artedian fyftem, of the genus of the gadi; and as the names taken from their colours, black and green, are very little expreffive, the colours being not perfect, permanent, or entire, Artedi has devifed others for them, by which they may be diftinguifhed at fight from one another. The *raw-pollack*, or cole-fifh, he diftinguifhes by the name of the *gadus* with three fins on the back, with no beard at the mouth, with the lower jaw longer than the upper, and the lateral line ftrait. The other, or *whiting-pollack*, he diftinguifhes by the name of the *gadus* with three fins on the back, with no beard, with the lower jaw longer than the upper, and the lateral line crooked. Thefe two kinds of *pollack* are by thefe names not only diftinguifhed from one another, but from all the other fpecies of the fame genus, as the codfifh, &c. *Artedi* Gen. Pifc. p 35.

POLLARD (*Cycl.*)—POLLARD is a name given by fome hiftorians to a fort of bafe money current at one time in Ireland, and called more ufually *crocards*.

Thefe were coins of France, and other nations, which paffed in Ireland as pennies, tho' really not worth quite half fo much. They were made of copper, with a very fmall admixture of filver. See the article CROCARDS.

It was in the reign of Edward I. appointed lord of that kingdom in the life-time of his father Henry III. that the ufe of falfe and counterfeit money of this kind was fo extremely common in Ireland. While his father reigned in England this prince never extended his power fo far as to fet up any mint, or coin any money in Ireland; but at his acceffion to the crown he found his treafury empty, and the current coin of his kingdoms in a very bad condition: his abfence of near two years after his father's death, having fo encouraged the clippers and coiners of money, that little but clipped, or counterfeit money of the kingdom was to be met with; and five or fix different forts of bafe and mixed money had been imported privately, and uttered in England and Ireland as pennies, tho' they were not half the value of the penny fterling.

Thefe were the *crocards* and *pollards*, called alfo *mitres* *[illegible]*, *rofaries*, and by the like names, according to the things marked in the impreffions. To remedy this evil, and reftore the current coin of the kingdom to its antient purity and value, this prince eftablifhed a certain ftandard; and as the bafe money was an admixture of a very fmall quantity of filver, with a great deal of copper, he ordered that there fhould be in every pound of money weighing twelve ounces, eleven ounces and two penny weight and a quarter of pure filver, and only feventeen pence halfpenny farthing allay.

The faid pound to weigh twenty fhillings and three pence in account; the ounce twenty pence, and the penny twenty-four grains and a half. According to this regulation, the money of Ireland was alfo ordered to be made, and a new kind of money was ftruck there in the year 1279, under Stephen de Fulbourn, bifhop of Waterford, and lord deputy of Ireland. The pieces coined at this time in Ireland were groats, or four pennies, halfpence, and farthings; and as thefe were the fame in value, as to weight, with the Englifh coins, they would go equally in England and Ireland: and in the twenty-ninth year of the reign of the fame prince, that is, in 1300, the *crocards*, *pollards*, and other bafe money were decried; and it was made death, with confifcation of goods, to import any of them.

By this means the circulation of the bafe and mixed money was in a great meafure ftopped, and four new furnaces were erected in the mint of Dublin, to fupply the great demand that there was for good money; and Almander Norman de Line was appointed mafter of the coiners. This was a beginning of good money in Ireland; and in the year 1304, there were fent over from England twenty-four ftamps for coining of money there, *viz.* three piles with fix croffes, for pennies; three piles with fix croffes, for halfpence; and two piles with four croffes, for farthings. In the old way of coining with the hammer, before the mill and fcrew were invented, two kinds of punchions were in ufe, the one called the crofs, whereupon was engraved the head of the prince; and this was fo called becaufe, antiently, a crofs was the figure ftruck on this fide of coins inftead of the head of the prince: the other called the pile, contained the arms, or fome other figure, to be ftruck with an infcription on the back, or reverfe of the coins. The pennies and halfpence ftruck in this king's reign, have the king's head in a triangle full-faced. The beft preferved of them, found at this time, weigh twenty-two grains the penny; and the halfpence from ten grains to ten and a half. The farthings are fo fcarce, that it is very rare to meet with one in the collections of the moft curious. *Simon*'s Hift. of Irifh Coins, p. 15.

POLLARD, in zoology, a local name for the young and fmall fifh of the cole-fifh, or rawling-pollack kind. It is ufed in Cornwall, *&c.* *Willughby*'s Hift. Pifc. p. 169.

POLLEN *thuris*, in the materia medica, a term ufed by the Latin writers, to exprefs the *manna thuris*, or *manna libanotis*, of the Greeks, but that very improperly; for the word *pollen thuris* properly fignifies the frankincenfe reduced to a powder, but this was not what the antient Greeks called *manna thuris*, but the fmall fragments which were broken off from the large pieces, in the gathering or packing up.

The *manna* ufed in medicine by the Greeks and Arabians was not formed into large flakes, as ours is; but was compofed of fmall fragments or grains, and therefore they called by the fame name the fmall granulæ or fragments alfo of other things: it was thus that the broken frankincenfe was called *manna thuris*.

The cuftom of the times of faving all the fragments of this drug, made them collect even what was in fo fmall pieces as to refemble powder; but this, tho' mixed with the reft, was not properly the *manna thuris*. This gave occafion to the adulterating this commodity, and Diofcorides tells us, that even in his time they had learned the trick of putting the powder of the refin of the pine tree among it; and this growing worfe and worfe, they at laft difcarded it, and would purchafe only the fragments without the powder. Thefe fragments they called *thus minutum*, to diftinguifh them from what was then called *manna thuris*, tho' improperly, and which was the adulterated mafs of refin and fragments of olibanum

POLLICIPES, the *toe-fhell*, in natural hiftory, the name of a genus of fhells, the characters of which are thefe: they are multivalve flat fhells, of a triangular figure, each being compofed of feveral laminæ, which end in a fharp point. They ftand upon pedicles, and are furnifhed with a great number of hairs. We have only one known fpecies of this genus, and this always found in large clufters See Tab of Shells, N° 27.

POLLINCTORES, among the antients, an appellation given to thofe who wafhed and anointed the dead. *Pitifc.* in voc.

POLLINCTURA, a word ufed by fome authors to exprefs the embalming dead bodies.

POLLING, in gardening, the operation of difperfing the worm-cafts all over the walks, with long afh-poles: this, befides deftroying worm-cafts, is very beneficial to the grafs of the walks. See GRASS-*walks*.

POLLUCTUM, among the Romans, a feaft kept in honour of Jupiter Dapalis, Hercules, *&c.* at which facrifices were offered to the Gods. *Pitifc.* in voc.

POLLUTION (*Cycl.*)—POLLUTIO *nocturna*, in medicine, the name of a difeafe, which confifts in an involuntary emiffion of the feed in the night, in time of fleep. This, in different perfons, is very different in degree; fome being affected with it only once in a week, a fortnight, three weeks, or even a month, and others being fubject to it almoft every night.

The perfons moft fubject to this, are young men of a fanguineous temperament, and who feed high, and lead a fedentary life. When this happens to a perfon but once in a fortnight, or a month, it is of no great confequence; but when it happens almoft every night, it greatly injures the health; the patients look pale and fickly. In fome the eyes become weak and inflamed; fometimes they are affected with violent defluxions, and ufually, at laft, are circled round with a livid appearance of the fkin.

This diftemper is to be cured rather by a change of life than by medicines. When it has taken its rife from high diet and a fedentary life, a coarfer food, and the ufe of exercife, will generally cure it; but if any medicines are to be given, nitre alone will do more than almoft all the reft. This may be taken in large dofes, a fcruple at a time, with very little liquid with it, and muft be continued for fome time at night going to reft. The root of the water-lilly is greatly recommended by fome in this cafe; and by others, the feeds of the agnus caftus; but it is very doubtful, whether they have either of them any effect.

Perfons fubject to this difeafe muft never take any ftimulating purges, and muft avoid, as much as poffible, all violent paffions of the mind: and tho' exercife is recommended in moderation, yet if this be too violent, it will rather increafe the diforder than do any thing towards its cure. *Junck*'s Confp. Med. p. 486.

POLPHOS, a word ufed by fome authors to exprefs a bulb or bulbous root.

POLPOCH, in zoology, a fpecies of ferpent faid to be found in Jucatan, a country bordering upon New Spain. It can bite with the mouth and fting with the tail. *Hoffm.* Lex univ. in voc.

POLVERINE, the calcined afhes of a plant; a fubftance of the nature of our pot-afhes, or pearl-afhes.

It is brought from the Levant and Syria; but in the glafs trade, tho' it be of the nature of the other afhes they ufe, it is always to be preferred to any other. The barillia, or pot afhes of Spain, yield more pure falt than the *polverine* of the Levant, but the glafs made with it has always fome tinge of bluifhnefs: that made with the *polverine* is ever perfectly white, and this is the fubftance that ought always to be ufed for the fineft cryftal.

The method of procuring the pure falt from thefe afhes, is to fift them and throw them in a proper quantity into a large copper of boiling water, continuing the boiling till all the falt of the afhes be diffolved by the water, and adding to the water, before the *polverine* is put in, about ten pound of tartar calcined to a blacknefs. The lee or water thus impregnated with the falt, muft ftand a confiderable time to fettle; and when perfectly clear, muft be evaporated till it thicken, and begin to fhew a white dry falt about its edges: then the fire muft be kept very flow, and a fkimmer full of holes being funk in to the bottom of the copper, the falt will gather and harden upon it; and this muft be taken out every now and then, and the falt taken off and dried for ufe. Three hundred pound of *polverine* thus yield eighty or ninety pound of clear falt. When this is dried, it muft be flightly calcined in the glafs furnace, and then powdered and fifted through a coarfe fieve, and kept dry. *Neri*'s Art of Glafs, p. 2.

POLYADELPHIA, in botany, a clafs of plants, whofe ftamina are formed into three or more feparate bodies.

The word is formed of the Greek πολυς, many, and ἀδελφα, communities. Among the plants of this clafs are orange-trees, St. John's wort, *&c.*

POLYANDRIA, in botany, a clafs of plants with hermaphrodite flowers, and a large number of ftamina, or male parts, in each. See Tab. 1. of Botany.

The word is derived from the Greek πολυς, many, and ἀνηρ, male. The hermaphrodite flowers of this clafs have a large number of ftamina on each, always more than twelve, and thofe growing to the receptacle of the future feeds.

Of this clafs are the water-lilly, poppy, celandine, *&c.*

POLYANTHEMUM, in botany, a name given by fome authors to the water-crowfoot, from its great number of flowers. *Ger.* Emac. Ind. 2.

POLYCEPHALON, Πολυκεφαλον in antiquity, a kind of poetry, for the nature and origin of which, fee Mem. de l'Acad. Roy. des Infcrip. Vol. 14. p. 438.

POLYCOMBUS, in botany, a name given by Neophytus and others to the common knot-grafs, more ufually called *polygonum*.

The name *polycombus* is formed of the Greek πολυς, many, and κομβος, a joint; and as it is ufually applicable to this, and all the other jointed plants, it is ufed by fome for the name of the feveral fpecies of equifetum, or horfetail, as the word *polygonum* is.

Neophytus defcribes one fpecies of this, which he fays is called *oreon*, from its growing in mountainous places. This, he fays, looks like a young reed, and has feveral joints in the main ftalk, which are received into one another as fo many cups or boxes. He adds, that the leaves are like thofe of the pine tree: what he calls the leaves, are probably the tender branches; and then this defcription will agree very well with our great marfh horfetail, which grows in wet places in mountainous countries, and about the fprings in our hills. This is the horfetail to which the greateft virtues are attributed by this author; but the whole account of the hippuris, polygonum, and equifetum, is fo confufed, that there is little to be learnt from what the antients fay of them, without repeating the trials of their virtues.

POLYCROTA, in the naval architecture of the antients, a word ufed to exprefs fuch of their gallies as had three, four, five, or more tires of rowers, feated at different heights; they were diftinguifhed by this term from the *monocrota*, or thofe which had only fingle rows of oars.

The number of rows of rowers in the *polycrote* gallies has given occafion to fome to fuppofe thofe veffels of fuch a height from the water as is fcarce credible; we have, however, no warrant for this, but the commentators have given occafion to the opinion, from their not having been able to ftow the rowers in lefs room, and have meafured the height of the veffel by their own fkill in this fort of architecture, not by that of the people who built them. Meibom has found a way to take off a great deal from the imaginary height of thefe gallies. He has two inventions to anfwer this purpofe: by the firft of them, he fhews how the lateral rowers may be fo placed, that he who fits behind another may move his hands and oar under the feat of the rower who fits next before him; by which means three lateral rowers, which, according to Scaliger's way of reckoning, would require thirteen feet and an half, will be placed in the heighth of feven feet and an half.

By the fecond invention, he finds out a place in the veffel for almoft half the number of rowers; forafmuch as on the fides of the aforefaid rowers, he places others in the middle of the fhip, upon tranftra or tranfverfe feats, which he imagines thruft out their oars under the feats of the lateral rowers; by this contrivance he has gained no lefs than nine feet in the heighth of a quinqueremis.

The different feries of rowers were called by different names; the *thalamitæ* were thofe who fat in the loweft row; the *zygitæ* were thofe who fat in the tranftra, or crofs feats; and the *thranitæ* thofe who fat uppermoft of all in the veffel.

The moft furprizing account of a *polycrote* veffel among the antients,

antients, is that said to have been built for Philopater, of forty tires of rowers. The next to this is that of Ptolomy Philadelphus, which is said to have had thirty tires; and in these there sat more than three thousand rowers. It has been disputed by many, whether such immense vessels as these were ever built, or ever could be used if built. The monstrous heighth they have been calculated to be of, according to the schemes of the generality of commentators, has rendered it incredible that there ever were any such; but Meibom has found out such convenient ways of placing the rowers in them, and has taken off so great a part of this imaginary heighth necessary in them, that he is clearly of opinion, that there were such vessels actually built and used.

The triremis, according to the computation of this author, contained two hundred men; of which one hundred and eighty were rowers, and the rest were mariners: so that the Athenian fleet, of which Conon was commander, consisting of one hundred and eighty triremes, there were in it six and thirty thousand men. The quinqueremis of these times contained four hundred and twenty men, three hundred of whom were rowers, and the rest soldiers; so that there are three stupendous things to be observed in regard to the Roman fleet at Messina, and the Carthaginian at Lilybæum: one is, that the former consisted of three hundred and thirty, and the latter of three hundred and fifty vessels, most of which were quinqueremes, which, according to the most accurate computation, were a hundred and fifty feet long; the number of men they contained was, in the Roman, one hundred and thirty thousand, and in the Carthaginian, one hundred and fifty thousand. The apparatus and provisions necessary for such a numerous host, is wonderful in these early days of shipping, and the accounts would be doubted, were they not given by one of the best of historians, Polybius, who wonders, as indeed he very well may, at such an amazing equipage for sea service at such a time.

POLYEIDÆ *sphragis*, the name of a sort of troches or pastils greatly used among the antients. It consisted of alum, four drachms; myrrh and aloes, of each five drachms; pomegranate-peel, and bull's gall, of each six drachms: all which were rubbed to fine powder, and made into troches with the bull's gall, mixed with a sufficient quantity of the most austere wine.

POLYGALA, *milkwort*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the personated kind, consisting of one leaf, not perforated behind, and divided before into two lips; the upper lip is bifid, and the lower one elegantly fimbriated. The pistil arises from the lower part of the flower, and ripens at length into a fruit or capsule of a compressed figure, divided into two cells, and full of oblong seeds. The fruit is usually found surrounded with the cup of the flower, which consists of five leaves, two large and three small ones, which clasp round the seed vessel in the manner of so many wings.

The species of *polygala*, enumerated by Mr. Tournefort, are these: 1. The great blue-flowered *polygala*. 2 The great purple-flowered *polygala*. 3. The great white-flowered *polygala*. 4. The common or smaller blue flowered *polygala*. 5. The common purple-flowered *polygala*. 6 The common *polygala*, with white flowers. 7. The painted-leaved *milkwort*, with purple flowers. 8. The painted-leaved *milkwort*, with blue flowers. 9. The narrow-leaved erect annual *polygala*, with dusky-coloured flowers, variegated with streaks of pale red. 10. The short-leaved pointed *polygala* 11. The little mountain myrtle leaved *polygala*. 12. The shrubby Portugal *milkwort*, with very small leaves, and large flowers. 13 The greater African narrow-leaved shrubby *polygala*. 14. The lesser African shrub-*polygala*, with very narrow leaves. 15. The flax-leaved American *polygala*, with very large flowers 16. The box-leaved shrubby African *polygala*, with very large flowers. 17. The box-leaved shrubby *polygala*, with yellow flowers. 18. The box leaved shrubby *milkwort*, with purplish red flowers. *Tourn.* Inst. p. 147.

The virtues of this plant have been very happily enquired into by the gentlemen of the royal academy of sciences at Paris, on occasion of the trials they made of the virtues of the Senekka rattle-snake root, recommended by Dr. Tennent; and their judging, that as his was the root of a species of *polygala* or *milkwort*, the roots of our common *polygala* might possibly have the same effects.

Dr. Tennent gives his rattle-snake root, or Virginian *polygala*, in the dose of thirty-five grains in substance, or in three or four ounces of a strong infusion, or in a yet stronger, in a proportionably smaller dose The effects of this root being found very great, it was supposed that its place might possibly be supplied by this species of our own growth. It is very certain, that the place of growth may, in some plants, make a very great alteration in their virtues; and that the different species of the same genus may, in other instances, produce different effects in the human body, some species of plants agreeing in their external forms and generical characters, while they differ in their virtues and qualities.

There appeared on trial a considerable difference to the taste between the American and the European *polygala*-roots, that of Virginia being very aromatic, acrid, and bitter, and the European only slightly acrid, with a very feeble bitterness. Another thing that gave great suspicion as to the parallel virtues of the roots of these two species was, that Gesner was found, in his account of the virtues of the European *polygala*, to call it a very brisk cathartic; a quality which might render its use very improper in many of the diseases in which Mr. Lemery and Jussieu found the Virginian kind to prove a serviceable medicine. This last was found always very speedily to allay fevers of the pleuretic kind, without increasing in any great degree the discharges by stool.

The roots of the European *polygala* being very small and slender, gave also some trouble as to the procuring them in sufficient quantity; and in hopes it might become a general medicine, it was determined to try the effects of the whole plant, root, leaf, and branch, in the disease in which the Virginian kind had been given with the greatest success, that is, in pleurisies; and this was accordingly fairly tried.

The principal instances of their trials were two; the first to a woman of twenty-two years old, who had a violent fever, with a sizy blood, and pain in the side. She was twice blooded, and had immediate but not lasting relief from it, and was ordered the common ptisans given on these occasions. The malady increased, and the expectoration was but small, and that of a thick yellow matter: a third bleeding finally was judged necessary, but was of no more service than the others; and after this she had the same ptisan continued, but with the addition of a large quantity of the common European *polygala*, stalk, root, and leaf. This took place in two or three hours, the expectoration became vastly plentiful, and the matter thin and white from being thick and yellow. The woman, in fine, was cured, and the medicine was not observed to occasion any nausea, nor did it prove, as supposed, a violent purge.

The second instance was in a man of a stout robust habit, and of twenty-five years of age. He was violently attacked with a pleurisy, he was bled seven times, and was brought into one of the hospitals delirious, and seemingly very near death: he was there blooded in the foot, which restored his senses; and he took a large quantity of the decoction of the *polygala*, which caused him to expectorate in great abundance. The matter was first blackish, then reddish, and finally white, and the patient was perfectly cured. Mem. Acad. Scien. Par. 1739.

These are such remarkable instances of the good effect of an herb to be had every where in our own country, that they seemed very worthy to be recorded. The plant grows with us on dry grounds and heaths, and is about four inches long, not erect, but trailing upon the ground: the leaves are long and narrow, of a pale green, and the flowers are large and look beautiful: they stand in spikes, and are usually blue; but very often white, and sometimes red. The herb should be pulled up root and all for drying.

POLYGAMIA, in botany, a class of plants, which have a diversity of combinations of the male and female parts of their flowers, and many ways of fructification in the same species; some having male flowers, others female, each distinct and perfect in its kind; and others mixed, or hermaphrodite, with both male and female organs of fructification in each. See Tab. 1. of Botany, Class 1.

The word is formed of the Greek πολὺς, many, and γαμος, marriage.

Among the plants of this class are the orach, pellitory of the wall, the ash, &c.

POLYGAMY, (*Cycl.*) is the marriage of one man to more than one wife, or the marriage of one woman to more than one husband

The last of these is the greater crime, as being most incompatible with the being of society, and might therefore be punished with greater severity.

It has been much disputed among the Doctors of the civil law, whether *polygamy* be adultery. In the Roman law it is called *stuprum*, and punished as such, that is, in some cases, capitally. See STUPRUM. But a smaller punishment is more consistent with the Jewish law, wherein the prohibition of adultery was perpetual, but that of *polygamy* temporary only. See Selden, L. 1. c. 9 de uxore Hebraica.

In Germany, Holland, and Spain, this offence is differently punished. By a constitution of Charles V. it was a capital crime. In England it is felony, by stat Jac. 1. but with benefit of clergy. In Scotland it is punished as perjury. See the article BIGAMY.

POLYGLOTTA *avis*, in zoology, the name of a bird described by Nieremberg, and which, he says, he saw and heard with admiration, singing in all tones. It is of the size of our starling.

Its back is brown, and its breast and belly white; and near the neck and tail it is variegated with spots and streaks of white Its head has a streak of white, which represents a sort of crown of silver. It is mightily esteemed, and kept in cages by the Spaniards, as infinitely superior to all other birds in melody. It feeds on almost any thing that is given it, and is most fond of the warmer climates; but endures the more temperate ones without harm. *Ray's* Ornithology, p. 305.

POLYGONATUM, *Solomon's seal*, in botany, the name of a genus of plants, the characters of which are, that the flower consists of one leaf, formed in the shape of a bell; but having a long tube, having no cup, and being divided into several segments at the end. From the bottom of this flower rises a pistil, which ripens into a soft roundish fruit, which contains a great number of roundish seeds.

There are a great many species of this plant 1. The common broad-leaved one. 2. The red-stalked broad-leaved one. 3. The great broad leaved one. 4. The white hellebore-leaved one. 5. The red-stalked white hellebore-leaved one. 6. The large sweet-flowered one 7. The double-flowered sweet broad-leaved one. 8. The little broad-leaved one, with large flowers. 9. The low English single-stalked kind. 10. The narrow-leaved single-stalked kind. 11. The narrow-leaved branched kind. And, 12. The climbing American kind. *Tourn.* Inst. p 78.

The root of *Solomon's seal* is a vulnerary of the very first rank; it is famous in bruises for taking away the marks, and for healing up fresh wounds; in both which cases, it is applied in form of a pultice. It has also been greatly celebrated in the cure of hernias, and for assisting in forming a callus in broken bones.

POLYGONUM, *knot grass*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the apetalous kind, being composed only of a number of stamina arising from a funnel-shaped cup, divided into many segments at the edge. The pistil finally becomes a triangular seed, which is covered by a capsule that was originally the cup of the flower. To this it is to be added, that the flowers grow in the alæ of the leaves, and that the roots are fibrous.

The species of *knotgrass*, enumerated by Mr. Tournefort, are these: 1. The common broad leaved *knotgrass*. 2. The white-flowered broad-leaved *knotgrass*. 3. The long and narrow-leaved *knotgrass*. 4. The short and narrow-leaved *knotgrass*. 5. The stone-*knotgrass*. 6. The great *knotgrass*, with long stalks and long leaves. 7. The broad-leaved sea-*knotgrass*. 8. The broad-leaved white flowered sea-*knotgrass*. 9. The Spanish sea-*knotgrass*, with very long stalks, and white flower-cups. 10. The broad-leaved shrub sea-*knotgrass*. 11. The round-leaved creeping Portugal sea-*knotgrass*. 12. The little hoary, sea-*knotgrass*. *Tourn.* Inst p. 510.

The antients as well as moderns have described the common kinds of *knotgrass* under the name *polygonum*; but as they have also given the same appellation to another plant, much error has arisen by mistaking these synonyms. Pliny began the mistake, and others have since in great numbers fallen into it, and thought Pliny's example a sufficient excuse.

The word *polygonum* being formed of the Greek πολὺς, many, and γονυ, joint, or knot, signified properly any plant that had several joints or knots. It was originally given to the *knotgrass* very properly, scarce any plant having more joints; but it was afterwards given also to a kind of equisetum or horse-tail.

The description of this was, that the stalks were hollow; the branches long, slender, and resembling rushes, or the twigs of the broom, but without any leaves; and that they were so brittle, that they could not be used as wyths, to bind things with, which seems to have been a use the common *knotgrass* was very frequently put to, and for which it was found very proper, because of the toughness of its branches. This kind of *polygonum* of the antients is said to grow in woods, at the roots of trees, as the horse-tails of several kinds do at this time; and tho' the descriptions of this and the other *polygonum* are so extremely different, this having no leaves, and the other being described by all to have small, oval, and pointed leaves, yet Pliny has confounded the two plants together, because both called by the same name; and has formed out of the description of different authors of these different plants, one general account, which he gives under the head of *polygonum*, and which can serve no plant at all. He says, it grows at the roots of trees, and climbs up them; and that it has long, rush-like, and brittle stalks, beset with small oval leaves. He even compares the branches to the hairs of a horse's tail, and yet did not find out at the time, that he was blending the description of the hippuris, or horse-tail, called by some the *female polygonum*, with the common *knotgrass*, or *polygonum* originally so called; a plant as different from it as one plant can well be from another. *Pliny*, l. 26. c. 13.

The common great *knotgrass* is esteemed a very powerful astringent. It is generally used in infusion, and is said to have great virtue in stopping hæmorrhages of all kinds. *Dale* Pharm.

POLYGRAM, in geometry, a figure consisting of many lines.

POLYHEDROUS *figure*, in geometry, a solid contained under, or consisting of many sides. See POLYHEDRON, *Cycl.*

POLYHISTOR, is used for a person of great and various erudition. See POLYMATHIA, *Cycl.*

POLYMORPHOS, variously shaped, an epithet often given to the os sphenoides.

POLYNOMIAL (*Cycl.*)—To raise a *polynomial* to any given power, may be done by Sir Isaac Newton's binomial theorem. Among other methods of demonstrating this, we have one by Signior Castillioni in the philosophical transactions, numb. 464.

POLYOSTEON, a name given by authors to that part of the foot which consists of a great many bones.

POLYPE, or POLYPUS, in zoology, a small fresh water insect, which, when cut into a number of separate pieces, becomes in a day or two so many distinct and separate animals; each piece having the surprizing property of producing a head and tail, and the other organs necessary for life, and all the animal functions. See Tab. of microscopical Objects, Class 1.

The first discovery of this animal was owing to Mr. Leuwenhoek, who, in the year 170?, presented to the royal society of London, a description of it, and an account of its uncommon way of producing its young: but the discovery of its amazing property of reproducing the several organs from its various pieces, was not made till the year 1739, by Mr. Trembley, at the Hague.

The production of its young is, indeed, different from the common course of nature in other animals; for the young one issues out from the side of its parent, in form of a small pimple or protuberance, which lengthening and enlarging every hour, becomes, in about two days, a perfect animal, and drops from off its parent to shift for itself: but before it does this, it has often another growing from its side; and sometimes a third from it, even before the first is separated from its parent. They breed quicker in hot than in cold weather; and what is very extraordinary is, that there never has yet been discovered among them any distinction of sex, or appearance of copulation; every individual of the whole species being prolific, and that as much if kept separate, as if suffered to live among others.

If the method of this little animal's producing its young be very amazing, its reproduction of the several parts, when cut off, is much more so. The discovery of this was perfectly accidental; for Mr. Trembley, who had often met with the creature in the water, and from its fixed residence in one place, and some other observations, not being able to determine whether it were an animal or a vegetable, made the trial by cutting it asunder, when, to his amazement, he found, that in a few days each of these pieces was become a perfect animal, the head part having shot forth a tail, and the tail a head. A thousand other trials, by cutting the animal in different manners, first by Mr. Trembley, and afterwards, at his request, by Mons. Reaumur at Paris, and Mr. Folkes, Mr. Baker, and the other naturalists in England, were the result of this; and all succeeded in the same manner, by whoever they were tried.

It is not easy to say what is the size of this creature; for it can contract or extend its body at pleasure from the length of an inch or more, and the thickness of a hog's bristle, to the shortness of a single line, with a proportionable increase of thickness. Its body is round and tubular, at one end of which is the head, surrounded with six, eight, ten or more arms, with which it catches its prey; and at the other, the anus and tail, by which it fixes itself to any thing it pleases.

There have been many different species of it discovered, the most elegant of which, the *polype a panna be*, or plumed *polype*, of Mr. Trembley, seems much to resemble the wheel-animal (so called from having the appearance of two wheels in its head) which Mr. Leuwenhoek discovered living in a sheath or case, and affixed to the roots of duckweed.

All the species are found in clear and slowly running waters, adhering by the tail to sticks, stones, and water-plants, and live on small insects They are easily kept alive a long time in glasses, often changing the water, keeping the glasses clean, and feeding them with a small red worm, common in the mud of the Thames, or with other small insects.

The creature has its name from the Greek πολὺς, many, and πὸς, a foot, signifying an animal with many feet; but a more apposite one might easily have been invented, since it has in reality no feet at all. What were originally taken for feet, are what have since been called its horns, and of late more properly its arms, their office being to catch its prey.

The several strange properties recorded of this animal, tho' very surprising, are, however, none of them peculiar to it alone. The Surinam toad is well known to produce its young not in the ordinary way, but in cells upon its back. Mr. Sherwood has very lately discovered the small eels in four paste to be each, without exception, full of living young ones. And as to the most amazing of all its properties, the reproduction of its parts, we know the crab and lobster, if a leg be broken off, always produce a new one: and Mr. Bonet, Mr. Lyonet, Mons de Reaumur, and Mr. Folkes, have all found on experiment, that several earth and water worms have the same property, some of them even when cut into thirty pieces The *urtica marina*, or sea-nettle, has been also found to have the same: and the sea-star-fish, of which the *polype* is truly a species, tho' it had long escaped the searches of the naturalists, was always well known by the fishermen to have it also.

Cluster-Polype, the name of a species of small insect of the *polype* kind, called by the French naturalists *polype a bouquet*.

There is found on several of the water-plants, and on other substances, as sticks, boards, and the like, accidentally fallen into the water, a whitish substance that at first sight appears to be only a sort of mouldyness; but if the bodies on which this is found, be put into a vessel of clear water, and the matter examined with a magnifying glass, it is soon seen that this whitish substance is really a vast number of small animals, which are almost continually in motion. When this is brought before the microscope, the form and structure of the creatures is very evidently distinguished, and they are found to be minute roundish creatures, severally affixed to the end of a sort of stem or tail; and many of the stems are so interwoven and united together, that they form *clusters*, which have occasioned the name of the *cluster-polype* to be given to the animal, tho' in itself it is really and properly single from the beginning. There are several species of *polype* of this minute kind, that *cluster* themselves in this manner together; and according to these and other circumstances, the *clusters* are found larger or smaller, and more or less complex. Phil. Transf. N° 474. p. 171.

The smaller *clusters* should always be chosen for observation, as in the larger the bodies of the several animals that compose them are apt to hide and obscure one another; but the most beautiful and accurate of all observations is to be formed when they are single, as they are sometimes found; and this is the only opportunity of seeing distinctly in what manner the *clusters* are formed.

One of these single animals is not in length above the 240th part of an inch, and is of a shape nearly resembling that of a bell: the anterior part of this generally appears open when it presents itself properly; and the posterior part is fixed to the stem or pedicle, by the other extremity of which the creature fastens itself to any solid body that it meets with. The body is of a brownish colour, except at the smaller end, which as well as the tail is whitish and transparent; and when the anterior part is open, there may always be perceived about its edges, a very lively motion; and when the creature presents itself in a better manner, there may be seen on either side of the edges of the anterior part, somewhat resembling the wheels of a mill, continually moving with great velocity.

These creatures are able to contract their bodies, and often do it very suddenly, especially if any thing disturb the substance on which they are fixed: when they are thus contracted, the edges of their anterior parts are drawn just into their bodies; and when the fright is over, it is a very agreeable sight to behold these edges turning out again, and putting themselves in motion as before. If the edges of the anterior parts of the bodies of these animals be strictly observed while in motion, the water about them will be found to be full of extremely minute round bodies which are brought together by means of that motion, and serve the creature for its food: these may be often seen going down into the cavities of the body of the *polype*, and that very suddenly, as if forcibly driven down; and when swallowed too voraciously, are often thrown up again. These observations are best made when a small *cluster* of the *polypes* are examined together.

If these *polypes* are kept some time in the rain-water, they by degrees lose their brown colour, and become white and transparent throughout, except that a few spots of a dusky colour remain in their bodies; but if after this they are removed into other water of the same kind with the first, but newly taken out of the ditch, they in a little time recover their brown colour. When they become white, they plainly appear to be in a sickly condition, and cease to multiply; but when they have fresh water and recover their colour, they immediately begin to multiply again.

These creatures are not absolutely and immoveably fixed to the bodies on which they are placed, but they can at pleasure quit them and swim about: in this swimming state they are always found single and not in *clusters*; and they do not then appear in the same form as when they are fixed and open at their anterior ends. When they have swam about as long as they please, they either return to their *clusters* from which they separated themselves, or affix each singly to any thing they meet with: and this is a circumstance that merits to be carefully watched, because it is by means of this that we see in what manner the creature multiplies itself, and the *clusters* are formed.

As soon as a single animal of this kind is fixed to a stick, a stone, or any other substance, it begins to lengthen its stem or tail, which tho' very short while swimming, and when first fixed, very soon becomes of its pristine length while in the *cluster*; and after this the creature begins immediately to multiply by the most amazing means in the world; that is, by spliting itself to pieces lengthways. The first motion towards this operation is the drawing in the lips or edges; this is soon done, and the body then loses its bell-like shape, and becomes round; the motion which was before perceived at the edges ceases, and there is only a slight tremulation to be seen within the body; after this the anterior part of the body becomes flat and broad, and the whole body shortens in proportion; and soon after this the whole body gradually splits itself regularly into two, from the center of the anterior part to the center of the hinder end, where it joins the tail or pedicle, and there soon appear two round and perfect bodies joined to that pedicle which before supported only one. The anterior parts of the two bodies soon begin to open, and gradually shew their edges, which perform the same motion the single one did before. The motion is at first very slow, but it grows quicker by degrees as they open; and when they are perfectly expanded, it is as quick as it was in the original single body: it is at this time that the two bodies may be esteemed quite perfect. They are at first indeed less than the original *polype*, from which they were formed, but they grow to the same size in a very little time: the whole operation of dividing itself, takes up the creature about an hour; but to form a true idea of the manner in which it is performed, there must be many observations made, and the creatures must be examined in all views and lights while about it.

The lips of these *polypes*, when closely examined, appear to be composed of four or five transparent bands, all which have an undulatory motion. And when the newly divided *polype* is but slow in its motions, it is easy to discover that what afterwards appear to be like the wheels of a mill, are, in reality, only four or five oblong bodies, resembling a sort of fingers which alternately bend down, and extend themselves every instant. These are fastened to the bands of the lips on each side of the mouth; and when they are put into swift motion in the time of the full growth and vigour of the animal, they are not to be distinguished, as to form, nor can their motion be otherwise discovered than by its swiftness, which makes it resemble the quick turning of a wheel.

When the separation of the body of a single *polype* of this kind is compleat, one sees two regular and perfect bodies adhering side by side to the same pedicle, but soon after each of the new formed bodies begins to shew a pedicle of its own; these grow in a day's time to a moderate length, and unite at their bottoms to the end of what was the original single pedicle of the body while but one; they grow to this in the manner of the branches growing to the trunk of a tree. Twenty-four hours after the separation of the original body into two, these two begin to separate themselves in the same manner, each into two again; and these after a like time again separate: each of these separated animals has its own tail formed in a like period of time with the first; and the consequence is, that the first separation producing two, the second gives four, the third eight, and so the sixth sixty-four, the seventh 128, and so on; by which means a single animal, in a very few days, forms out of itself an immense *cluster*; each animal of which is perfect in itself, and independent of all the rest, and can, when it pleases, swim away and form a new *cluster*. They will multiply as fast in glass jars, as in their native free state in the waters, and *clusters* of them, begun near one another, will often join in such a manner as to form one complex *cluster* of an inch diameter: from these several *clusters* there detach themselves single *polypes* from time to time, which go off and fastening themselves to other bodies, become the authors of new progenies. Phil. Transf. N° 474. p. 175.

The original branch or stem of the first *polype*, remains always in the center of the *cluster*; but it is of no use, never afterwards having any body fixed to it.

There are, beside this species here described, four other known kinds of *polypes*, which divide themselves in the same manner by spliting into two lengthwise: those which come nearest to the first are slenderer, and their stems are more transparent. They are of a bluish colour, when many of them are seen together, and their stems or tails very aptly resemble spun glass. When this species is perfectly formed, the motion of its lips is less distinct than in the other; but it may be discovered in the same manner while they are newly separated and are but growing toward perfection, when it gradually becomes less and less distinct.

Another species of these *polypes* is smaller than the last, but more open at the mouth and deeper hollowed; and these are particularly distinguished from all the others, by having a motion in their stems and branches, which all the others want. The stems draw themselves up, and shorten all at once into the appearance of a spiral screw, and in a moment can dart themselves strait out to their full length again. All these multiply very speedily, but they have all enemies that destroy them in a very terrible manner, whole *clusters* making but single mouthfuls. The *funnel-polypes* are nearly allied to these creatures. Phil. Transf. N° 474. p. 180.

Funnel-Polype, a name given by naturalists to a small water-insect, in some respects approaching to the nature of the cluster-*polype* See *Cluster* Polype, supra

The *funnel polype* nearly resembles a funnel, from which it has its name. It is long and hollow, and very wide at the anterior end. These little animals are of three species, a green, a blue, and a white one: they are all too minute for the observation of the naked eye, and must be viewed with great caution, and in several different directions and attitudes, before their true form can be discovered; and their anterior end, particularly, when carefully observed, is of a much more

compound structure than might at first be imagined; there may always be observed, round the edges of this part, a sensible motion, resembling that of an indented wheel, or rather that of a screw turned very nimbly about. These, tho' they approach to the shape of the cluster-*polypes*, and resemble them in their having this motion about their mouths, yet never have any tendency to form clusters, but are ever found loose and single. There are always a number of little round bodies, which seem to be animals of a very minute size swimming about in the water in which these *polypes* live; and these are continually drawn into the mouths of the *polypes*, and serve them for food.

The manner of these creatures propagating themselves, is very amazing; they do it by dividing their own body into two; but this is not done longitudinally, as in the cluster-*polypes*, nor transversely, but diagonally from the edge of the head to the opposite edge of the tail; so that of the two thus formed out of one, the one has a head and no tail, the other a tail and no head; but these deficiencies are soon made up, and the head soon grows out of one, and the tail out of the other. Mr. Trembley, in his account of this insect, calls that of the two which has the old head, the superior *polype*; that which has the old tail the inferior. The first particulars observable in a *funnel-polype* that is going to divide, are the lips of the inferior *polype*, or those transparent edges that are so very conspicuous in the creature when perfectly formed. These new lips first discover themselves upon the *polype* that is going to divide, from a little below the old lips to about two thirds of the length of the *polype*, reckoning from the head: but these new lips are not disposed in a strait line, according to the length of the *polype*, but run sloping near half way round about. These lips are distinguished by their motion; but it is to be observed, that this motion is at first very slow, and requires an attentive eye and good glasses to discover it. Phil. Trans. N° 474. p. 180.

That portion of the body of the *polype*, which is bounded by these new lips, then gathers up itself, and these lips insensibly draw close together, and finally they close themselves. By this means there is formed a swelling at the side of the *polype*, which is found, on a close examination, to be the head of the new *polype*, bounded by the lips before-mentioned. Before this swelling is become very remarkable, it is easy to discover the true *polypes* that are forming themselves; and after this, when the swelling is greatly increased, these two distinct animals will be found joined to one another only by a very small part of their bodies. The superior *polype*, in this case, no longer adheres to the inferior one but by its posterior extremity, which is still fixed on one side of the inferior one. The superior one then begins to make motions, which tend to the separating itself from its fellow; and these soon finish the work, and he becomes perfectly disengaged, and swims away whither he pleases, and soon fixes on some other place. The inferior *polype* remains fixed in the place where both were before, and becomes a perfect animal; and the superior one, after taking a tour in the water, sometimes returns to the old place, and fixes himself by the tail to the body of the inferior one. All these animals are extremely minute, and are not to be seen distinctly, much less are their operations observed without the help of glasses; and as there is no taking them out of the water to bring them before the microscope in the common way, without absolutely destroying them, Mr. Trembley, who has observed them with more accuracy, than perhaps any other person ever did, has contrived to view them in a glass vessel, in their own water, by bringing them so near the sides of the glasses, that the microscope glasses are able to reach them properly from the outside. The substances on which they are fixed, are to be brought close to the edges of the vessel, by means of a set of quills framed properly together; and the microscope glasses to be supported on a moveable arm made for that purpose. Phil. Trans. N° 474. p. 183.

Ver-POLYPE. See VER-*Polype*.

POLYPODES, a word used by some as a name for the millepedes.

POLYPODITES, a name given by the antients to a wine impregnated with polypody, and sometimes for the juice of millepedes, expressed with wine.

POLYPODIUM, *polypody*, in the Linnæan system of botany, the name of a genus of the capillary plants, comprehending the *polypodium* and *lonchitis* of Tournefort; the *lonchitis* of Linnæus being a very different genus of plants. The character of the *polypodium* is, that the fructifications are disposed in round spots on the under part of the disk of the leaf.

The characters of this genus, according to Mr. Tournefort, are these: The flowers are not discovered, but the seeds grow on the back of the leaf: these are contained in membranaceous capsules, of a roundish figure, which are placed together in clusters, and have nothing round them, as those of the trichomanes have, but are left to be burst by the contraction of their own fibres.

The *polypodies* are not branched, but consist of single leaves, divided almost to the middle rib into oblong jaggs or segments.

The species of *polypody*, enumerated by Mr. Tournefort, are these: 1. The common *polypody*. 2. The common great *polypody*, with serrated leaves. 3. The lesser *polypody*. 4. The large *polypody*, with pointed leaves. 5. The broad thin-leaved *polypody*, called by Muntingius, and others, sensitive *polypody*. 6. The narrow-leaved *polypody*, commonly called *lonchitis aspera*, and rough *spleenwort*. 7. The Welch *polypody*, with leaves jagged at the edges of the pinnules. 8. The finely divided African *polypody*. 9. The great golden *polypody*. 10. The *polypody* with slender creeping roots. 11. The finely divided black *polypody*. 12. The *polypody* with leaves like the asplenium. 13. The thin-leaved pendulous *polypody*. 14. The *polypody* with pointed and rigid pinnules. 15. The pendulous *polypody*, with a reddish hairy down. 16. The smooth pendulous *polypody*. 17. The least pendulous *polypody*. 18. The curled *polypody*, resembling the ostrich's feathers. 19. The rough dentated *polypody*. 20. The slender undulated *polypody*. 21. The curled *polypody*, with cups. 22. The sweet *polypody*, with the taste of liquorice. 23. The *polypody* covered with silvery scales. 24. The brown finely serrated *polypody*. 25. The pellucid *polypody*. 26. The *polypody* with bluish punctated roots. *Tourn.* Inst p. 540.

The common *polypody* is the kind used in medicine; it is usually found about the roots of old trees, in woods, and by hollow road sides. There is a vulgar opinion, that such of it as grows upon the stump of an oak, is preferable to what grows on any other tree; but there is no foundation for this. The root is the part used in medicine; it is a gentle cathartic, and is particularly recommended in disorders arising from obstructions of the liver and spleen. It is by many esteemed an excellent medicine in scorbutic and hypocondriac complaints. The country people take it in infusion alone, but physicians usually prescribe it in compound decoctions and medicated ales. It has also been made an ingredient in many of the purging electuaries in the old dispensatories.

POLYPOSIA, a term used by the antients to express a copious drinking of wine.

POLYPUS (*Cycl.*)—POLYPUS, the *polype*, in zoology. See the article POLYPE.

POLYPUS, in natural history, a name given by some of the earlier writers to the thin-shelled nautilus, or nautilus papyraceus. The body and arms of this creature somewhat resembling those of the polype, it was supposed to be a species of polype inclosed in a shell, which it could quit occasionally, and go on shore to feed.

POLYPUS, in medicine.—Mr. Le Dran cured a *polypus* of the nose, which he could not extract wholly, in the following manner, which may be practised for destroying all such excrescences. He introduced one end of a large seton, put on the point of the fore-finger of the left hand, into the patient's mouth, till he brought it behind the velum pendulum; then sliding a pair of thin crooked forceps into the affected nostril, he catched hold of the seton, after covering what was to be introduced into the nose with a suppurant medicine. While he drew the cord, he endeavoured to preserve the velum pendulum from being hurt, by introducing his finger into the mouth, and supporting the cord upon it. He continued the suppurant till he was sensible, by the patient's breathing freely through the nostril, that the remains of the *polypus* was destroyed, and then he injected desiccatives to cauterize the ulcer. *Le Dran*, Tom. 1. obs. 6. ap Med Ess. Edinb.

Though Kerkringius, and others, have endeavoured to explode the notion of the formation of true *polypi* in the heart and blood vessels, yet Malpighi, Bartholine, Tulpius, Pecklin, and others, have given us incontestable instances of the existence of true *polypi* in the heart, in the strictest sense; and we have three unquestionable evidences of the like nature, in Phil. Trans. N° 464. Sect. 6.

POLYSACTINODOS, in natural history, a name given by Linkius, and some other authors, to those star-fish whose body is divided into more than five rays, that being the more usual and general number.

POLYSCHIDES *fucus*, a sea-plant, called in English *sea-hanger*. It is one of the largest sea-plants we know, growing often to ten foot or more in length. Its root is not flat in the manner of most of the other sea-plants, but is composed of several little hooks, all which lay fast hold of the stone on which it grows: these, in some measure, resemble the tendrils of the vine, and are somewhat broad and flatted at the end, where they are fastened to the stone, tho' round elsewhere, and are about half an inch long: these hooks grow from a broad flattish part at the bottom of the stalk, which is often four or five inches in diameter, and is usually hollow, being composed only of two membranes considerably tough and firm, with a cavity between them; from the center of this rises the stalk, which is often twisted and undulated at the edges; from the top of this stalk grows the leaf, which is divided into eight or ten segments; each of which is often again divided into two. These segments are very long; and as the plant floats in the water, give it much of the appearance of a broad piece of leather cut into several thongs: these all terminate in sharp points, and their colour is a brownish green. The nicest eye cannot distinguish the least nerve or fibre, either in the stalk or leaf of this plant; but on great numbers of these plants, that curious enquirer Mr. Reaumur, found flowers of the same kind with those which he originally discovered on

the common fences: they are composed of slender filaments, not exceeding the twentieth part of an inch in length; and these were the more easy to be overlooked, as they are of the same colour with the leaves of the plant. Those plants on which Mr. Reaumur found these flowers, were not, however, entirely covered with them, but they stood at about a twelfth of an inch distance from one another: it was in the month of July that Mr. Reaumur examined this plant; and at that time there were no seeds discoverable upon it; but doubtless at a proper season, and with proper care in the observer, they will hereafter be discovered as plainly in this as in many other of the sea-plants, usually supposed by authors to have wanted them. Mem. Acad. Par. 1712.

POLYTHALAMIUM, in natural history, a name by which some authors have called the *tubuli marini concamerati*, a sort of sea-shell found frequently fossile, with other shells, in Sweden, and brought over to us in the stones used for pavements, but not known in its recent state.

It is of the same general structure with the cornu ammonis, and thick nautilus, being composed of several cells or cavities, communicating with one another, by means of a siphunculus or pipe; but it is usually strait, tho' sometimes its end is twisted exactly in the manner of the cornu ammonis.

POLYTHALAMIUS, in natural history, a term invented by Breynius, to express a class of shells, the character of which is, that they are hollow, shelly bodies, either strait or regularly twisted into a spiral form, always wide at the mouth, and growing narrower to the other extremity; they are divided within into several cells or chambers, which are called *thalami*, each separated from the other by a diaphragm, or partition of shelly matter. The upper or largest chamber, contains the body of the animal, but all the others are perforated by a siphunculus, which gives them communication one with another, and which runs from the mouth to the very apex, growing slenderer all the way.

Of this class he distinguishes four genera, the orthoceros, lituus, ammonites, and nautilus, each of which see under their several heads. The two last of these, he observes, have been long well known to the world; the two first he gives as new, and of his own discovery.

Of the orthoceratitæ, which are stones cast in the shells of the orthoceros, there are at present distinguished nine kinds: these differ from one another principally in the position of the siphunculus, or in their external form; the cone which they describe, running quicker or more gradually to a point; or, finally, by the thalami or chambers being wider or narrower. *Breynius* de Polythalam.

POLYTHRIX, the *hair-stone*, a name given by some writers to those German agates which have received into their mass, while yet soft, either the branches of the confervæ, or other capillary water-plants, or else have thin streaks of a coarser matter frequent in them, and running in the form of hairs.

POLYTRICHUM, in botany, the name of a genus of mosses, the characters of which are these: The stalks are not much branched, and the capsules have calyptræ to cover them till mature. This calyptra is always hairy, and in many of the species is composed merely of long hairs, ranged lengthwise together, without any membrane; the others have membranaceous calyptræ, but covered with erect hairs. The leaves of those kinds are rigid, and have a membranaceous appendage, by which they touch the stalks and surround them; those of the others are softer, and have not this appendage. The basis of the pedicle which supports the head, is also in these surrounded by a sort of tube, round which there stand a number of membranaceous leaves; this is more visible in the larger than in the smaller species. The capsules in some of these mosses are square, in others they are roundish; and the square ones have usually an apophysis, by which they are joined to the pedicle, which the round ones never have, or at least very seldom. See Tab. of Mosses, N° 12.

The *polytrichum* of the first order, are those which have square capsules, which are joined to the pedicles by a round apophysis; of these the following are all the known species: 1. The common large, square-headed, great-leaved *polytrichum*, or great goldilocks. This is very common in woods, in boggy places, and on heaths. 2. The lesser and stiffer square-headed juniper-leaved heath-*polytrichum*. The leaves of this are short, and the whole plant much smaller than the former. It is very common on heaths. 3. The small hairy square-headed *polytrichum*; the leaves of this are of a bluish green in winter, and of a reddish brown in summer. It grows in dry barren places.

The second order of the *polytrichum* comprehends those which have round capsules, and usually want the apophysis, by which the others are joined to the stalk. The following are all the known species of this kind: 1. The branched alpine *polytrichum*, bearing heads from its tops. The leaves of this are narrow and somewhat hollowed, and when viewed by a microscope, appear serrated at the edges. It grows on the Welch mountains. 2. The branched *polytrichum*, bearing heads from its sides. This grows to two inches high, and is found in the same places with the former. 3. The dwarf round-headed aloe-leaved *polytrichum*. This has scarce any stalk, but lies upon the ground; it is frequent by way sides, and ripens its capsules early in the spring. 4. The dwarf long-headed aloe-leaved *polytrichum*. The stalks of this are a little longer than those of the former. It grows in wet places on heaths. 5. The larger short-shanked *polytrichum*. This is branched, tho' very low, and resembles at first sight one of the bryums, growing in round tufts. The leaves are of a deep green, and very pellucid; they have a middle rib visible in them, and are disposed in somewhat of a stellate manner at the ends of the branches. It grows in woods on the barks of old trees, and sometimes on walls. 6. The lesser short-shanked *polytrichum*. This is much smaller than the former, and produces its capsules a little later. It grows on trees and walls, and sometimes on the earth. 7. The short-shanked *polytrichum*, with strait and plaited leaves. This grows in tufts. Its stalks are an inch high, and its leaves of a dark green. It grows on rocks and old walls. 8. The fine-leaved curled *polytrichum*, with sharp hairy calyptræ. This is found in tufts composed of thick branches, surrounded with very numerous leaves, each ending in a hair at the end. It grows in woods, and ripens its capsules in March and April. 9. The dwarf fine-leaved *polytrichum*, with cylindric heads. This grows on sandy places in north America. *Dillen* Hist. Musc. p. 430.

Old writers are very full of the praises of this plant for its virtues in making the hair grow thick; but this seems to have been an opinion taken upon no better reason than the likeness of the stalks of the plant to hairs. They make a decoction of it in some parts of Germany, and wash the head carefully with it in the increase of the moon; but there is no great reason for supposing this liquor does any thing more than warm water would do.

POLYTROPHEROS, a name given by the Greeks to coarse bread, from its conveying much more nourishment to the body than the finer kind; which they called, by way of distinction, *oligotropheros*.

POLYZONOS, in natural history, a name given by the antients to a species of onyx, which had a dark or blackish ground, with a great number of white zones.

POMA, in the writings of the old Greek physicians, a word which has given the commentators a great deal of trouble rightly to explain. Dioscorides, in describing the *onyx indicus*, which we improperly call *blatta byzantia*, tells us that it was like the part of that shell usually called by the name of *byzantine blatta*, but that it was in reality the *poma* of another shell.

Some have understood Dioscorides, as if he meant that the whole shell of the fish, which he describes as being like the purpura, was what he called *onyx indicus*; but it is not easy to say why so correct an author should call a whole shell *poma conchyli*, nor what resemblance there could be between a shell like the purpura and a human nail, *onyx?* Actuarius, and many others, sensible that a part of a shell only was meant by this name, have translated it the *os nasi*; but the bone of the nose of a shell-fish is so odd an expression, that one scarce knows what to understand by it.

The purpura of the antients has a long tongue, with which it pierces the shells of the chamæ, and other fish that it feeds on; but whether this or the operculum, which all shells of this kind have, is meant by the word, is not to be ascertained by this phrase *os nasi*.

The true meaning of the word is to be made out before any thing can be judged of what is meant to be expressed by it here, where it is evidently used in a metaphorical sense.

Brassavolus says, that it means all sorts of shelly or crustaceous coverings of fishes; but this is an absolute error; for even the medical authors do not extend its sense so far as that. The Greeks called all shells by the name *ostraca*, and this author attributing a different virtue to the whole shell of the purpura, sufficiently speaks this *poma* to have been but a part of it.

The Arabian writers were sensible of this, and rendered it by the words *adsor althaib*, which signify fragments like nails. Serapio calls it *mukatha*, which signifies a morsel or piece of any thing cut from a solid body. The original sense in which the Greeks used the word *poma*, was to express the thing that closed the mouth of any vessel with a long and narrow neck. The Latins expressed this by the word *operculum*, and sometimes, as in Sulpicius Severus, by the word *umbo*.

The antients also used the word *poma* to express the lid or covering of a well, or of any hole. Now the purpuræ buccina, and all those other shells which the Greeks have called *stromboide*, may in some sort be compared to narrow and deep vessels, and they have all of them a sort of *poma*; or, as the Latins have expressed it, an *operculum*, to stop the mouth of the shell, and prevent the ingress or egress of any thing at the creature's pleasure. This *operculum* being what Aristotle has called *epicalymma*, is certainly also what Dioscorides means by the word *poma*; Aristotle has been very express in his description of it, and says that the tongue lies under it, and that all the *stromboide* shells gave it. The *onyx indicus*, therefore, was only the *poma*, or *operculum* of an Indian *stromboide* shell, of the buccinum or purpura kind, and was of a sweet smell, and thence had the term *aromaticus*, or *odoratus*. The name *onyx* is easily accounted for, as the *poma* of every shell of this kind is flat and thin, and does not unaptly resemble the human nail.

POMATIA, in natural hiftory, the name of a large fpecies of garden-fnail, fo called from its feeding on apples and other fruit. It is originally a native of Italy, but is become of late years as familiar with us in England, as if a native with us. It is a noble remedy in confumptive decays; and a perfon of diftinction in England having occafion to take great numbers, had feveral large parcels brought carefully alive from Italy, and turned loofe in his garden, where they multiplied to fuch a degree, that the neighbouring woods and hedges foon became full of them, and they have fince been propagated in many other places.

The *pomatia* is much larger than our common fnail, and of a paler colour: it is of a roundifh figure, and has five fpires or twifts at the head; thefe are placed very clofe, and its mouth is large and almoft circular, and has no duplicature or fold furrounding it, but it is as thin as the reft of the fhell.

POMEGRANATE, in botany. See PUNICA.

POMERIUM, in antiquity. See POMOERIUM.

POMOERIUM, among the Romans. Authors are not agreed as to particular circumftances relating to the *pomoerium*; fome will have it to be a fpace of ground without the walls; others a fpace within them; and others again think it was both within and without. But which ever of thefe is true, the *pomoerium* was a place efteemed facred, and kept free from houfes and every other kind of obftruction. Hift. Acad. Infcr. Vol. II. p 91, feq.

POMPEION, Πομπειον, in antiquity, a ftately edifice at Athens, in which were kept the facred utenfils, made ufe of at feftivals, and all things neceffary for the folemn proceffions prepared. It ftood at the entrance of the old city, which looked towards Phalerum, and was adorned with many ftatues of the Athenian heroes. *Potter*, Archæol. Græc. l. 1. c. 8. T. 1. p. 34.

The word *pompeion* is derived from πομπευω, *cum pompa incedo*, and was likewife ufed for any utenfil employed on thefe occafions.

POMPILUS, in zoology, the name of a fea-fifh, remarkable for following the rudders of fhips to vaft diftances. It has no fcales: it has a very broad line from the gills to the tail, under which are a number of dotted tranfverfe lines, reaching to the belly, above the line on the fide; the back is fpotted with different colours. The mouth is moderately large, but the teeth very fmall. Its forehead, between the eyes, is of a gold colour, and it has four fins, two at the gills and two on the belly; and befide thefe, one long one running all the length of the back, and another anfwering it from the anus to the tail. It tail is not forked. *Rondelet.* de Pifc. p. 250. *Gefner* de Pifc. p. 887.

POMPILUS is alfo ufed by fome authors for the nautilus, as well of the papyraceous, as the camerated kind. See the article NAUTILUS.

POMPION, in botany. See the article PEPO.

POMPONA, a name given by the Spaniards in America to a fort of *vanilla*, the pods of which are fhorter and thicker than thofe of the common kind, and of a ftronger fmell, tho' lefs agreeable. The pulpy matter alfo in thefe pods is more liquid than that in the common kind, and the feeds much larger, being as big as thofe of muftard. This is never brought to market alone; but the Indians who gather it, cunningly mix it among the right kind; but this fhould be taken care of by the buyer, fince this kind is very prejudicial, occafioning violent head-achs in men, and in women vapours and diforders of the womb.

It is not yet certainly known whether this be the fruit of a different fpecies of the *vanilla* plant, or whether it be only different from the common in age, or in the place of growth of the plant.

POMUM, *apple*, a well known fruit. See APPLE.

Among the various kinds of *apples*, fome are ufed for the defert, fome for the kitchin, and fome for cyder-making.

Thofe ufed for the defert, are the following, placed as they fucceffively ripen after one another: The white juncating, the margaret *apple*, the fummer pearmain, the fummer queening, the embroidered *apple*, the golden reinette, the fummer white calville, the fummer red calville, the filver pippen, the aromatic pippen, la reinette grife, la haute bonte, the royal ruffetting, Wheeler's ruffet, Sharp's ruffett, the fpine *apple*, the golden-pippen, the nonpareil, the l'api, or pomme d'api.

Thofe for the kitchin ufe, in the order of their ripening, are thefe: The codling, the fummer marygold, the fummer red pearmain, the Holland pippen, the Kentifh pippen, the courpendu, Loan's pearmain, the French reinette, the French pippen, the royal ruffet, the monftrous reinette, the winter pearmain, the pome violette, Spencer's pippen, the ftone pippen, and the oaken pippen.

Thofe moft efteemed for cyder are, the Devonfhire royal wilding, the redftreak *apple*, the whitfour, the Herefordfhire under leaf, and the John *apple*, or deux annes.

The feveral forts of *apples* are defigned either for ftandards, or in dwarfs or efpaliers; thofe that are defigned for ftandards fhould be grafted on crab-ftocks, and thofe for dwarfs or efpaliers, on the codling, or fome other fpecies, which does not fhoot freely. See the article GRAFTING.

The beft feafon for planting out thefe trees is, if the foil is dry, in October; but in a wet foil 'tis beft to defer it till February. The diftance at which they fhould be planted, is forty feet fquare, that the fun and air may have room to come every way at them: And 'tis a very good method in large orchards, to plough and fow the ground between them, till they are grown up. Good thriving trees of about three years grafting, are to be chofen for planting; and they fhould be taken from a foil as nearly as poffible of the fame nature with that they are to be planted into, or rather from one that is fomething poorer. In preparing thefe trees for planting, all the broken or bruifed roots are to be taken off, as alfo all fuch as crofs and gall one another, and all fmall fibres; for thefe feldom furvive a remove. Some of the moft luxuriant branches muft be alfo taken off at the fame time, and others fhortened, but the head fhould by no means be cut off. The holes for the planting them fhould be made about two foot deep, and of a breadth proportioned to the extent of the root; the bottom muft be made even, and the clods and lumps all broken. The tree is then to be fet in the middle of the hole, and placed as upright as poffible, and the earth carefully placed about its roots; and, finally, trod down about it with the feet; and if the weather be dry, every tree fhould have a good watering, which will fix the earth to the roots. A ftake fhould alfo be fixed by the fide of each tree to tie it to, that the wind may not fhake it and loofen the roots. The foot of each tree fhould be then furrounded with turf newly cut, with the green fide downwards; which will greatly help to keep the earth moift; and if the feafon be very dry, the waterings muft be repeated at different times; but it is a very common error to water new-fet trees too much; and this fhould be carefully avoided. The year afterwards dig in the earth about the roots, and bury the rotted turff, which was laid about the root when planted, and there needs no farther care; the orchard will then thrive of itfelf.

Dwarf ftandards are of the leaft value of all *apple*-trees, never producing well-tafted fruit; and are therefore the worft way of managing this tree.

Efpaliers are commonly planted to furround the quarters of kitchin gardens. Thefe quarters fhould be made as large as the garden-room will permit. The trees fhould be planted at fixteen or eighteen feet afunder, if on crab-ftocks, but if on paradife-ftocks, twelve feet will be fufficient; when thefe are planted in the manner above-defcribed, they fhould be headed to about four eyes above the graft, and they fhould never be of more than two years old from the grafting when planted. The fummer after they are planted, a number of fmall ftakes muft be provided, of about three feet long, to drive into the ground on each fide of the trees, four to each tree; and to thefe ftakes the new fhoots muft be faftened as horizontally as poffible. If the trees have taken kindly, probably about Michaelmas all the four eyes will have made fhoots; if fo, at Michaelmas, which is the right time for pruning, the two upper fhoots fhould be cut off to four eyes each, but the undermoft may be left with fix or eight; but the branches fhould never be fhortened in fummer, unlefs on occafion of filling up fome vacancy in the efpalier, and then this muft not be done after May.

In the fecond year, all the fhoots muft be trained horizontally, except the fore right ones, which muft be difplaced as faft as they are produced: at Michaelmus, the branches in the middle of the tree, or wherever there is want of wood, muft be fhortened; but after this be very careful of any great lopping, or fhortening of branches, but leave them at full length, training them all horizontally. *Miller's* Gardners Dict.

POND (*Cycl.*)—POND-*weed*. See POTAMOGEITON.

Fifh POND. See the article FISH.

PONENDUM *in ballium*, in law, a writ commanding that a prifoner be *bailed*, in cafes bailable. Reg.Orig. 13. *Blount*, *Cowel*.

PONENDUM *figillum ad exceptionem*, a writ by which juftices are required to put their feals to *exceptions* exhibited by the defendant againft the plaintiff's evidence, verdict, or other proceedings before them, according to Stat. Weftm. 2. *Blount*, *Cowel*.

PONENDIS *in affifis*, a writ granted by the ftatute of Weftm. 2. c. 38. which ftatute fhews what perfons fheriffs ought to impanel upon *affifes* and juries, and what not. Reg. Orig. 178. F. N. B. 165. *Blount*, *Cowel*.

PONTAGIA, a term ufed by Paracelfus, and his followers, to exprefs a mixing faline fubftances, with thofe which are bitter or ftyptic.

PONTEE, in the glafs trade, an iron inftrument ufed to ftick the glafs at the bottom, for the more convenient fafhioning the neck of it. *Neri's* Art of Glafs, Appendix.

PONTEE-*ftake*, in glafs making, is the iron whereon the under fervants place the irons from the upper workmen, when they have knocked off the broken pieces of glafs. *Neri's* Art of Glafs, Appendix.

PONTICA *gemma*, a name given by the antients to a ftone of the agate kind, with a white ground and red and black fpots, irregularly placed, and making a beautiful variegation in it. This feems to have been the fame ftone which fome of the moderns have called the *fmall fox ftone*, from its fpots refembling the eruptions in that difeafe. The antients mention feveral kinds of it, as they were fpotted with various colours.

PONTICA *vina*, a term ufed to exprefs acid, fæculent, and tartarous wines.

PONTICUM *mel*, a name given to a fort of poifonous honey

PONTICUS *mus*, in zoology, the name of a creature defcribed by the antients, and fuppofed to be the fame with our fquirrel. See SCIURUS.

PONTLEVIS in the manege, a diforderly refifting action of a horfe, in difobedience to his rider; in which he rears up feveral times, and rifes fo upon his hind legs, that he is in danger of coming over. It is cured by clapping fpurs fmartly to him, as the fore feet are returning to the ground.

POOL (*Cycl.*)—POOL-*fnipe*, in zoology, a name given in many parts of England to the redfhank.

POOR, or POWER, in ichthyology, a name given by the people of Cornwall to a fpecies of bearded gadus. See the article GADUS.

POOSPANSCUM, in natural hiftory, the name of a peculiar fpecies of foffil in the Eaft Indies. It is of the nature of the blende, or mock-lead, with us; but is not formed into fo large flakes, but more refembles the fteel-grained lead ores. It is found in the beds of rivers, and when calcined, it is ufed with the juices of certain herbs, for ulcers and other cutaneous diforders. Before calcination it is alfo ufed by the women to make their hair of a fine gloffy black colour, which it performs very neatly.

POPÆ, among the Romans, were fuch perfons as attended the facrifices, whofe bufinefs it was to provide victims, and to kill them after they had knocked them down. They were half naked, their fhoulders, arms, and upper parts of their bodies being uncovered as far as their navels, and the reft covered to the mid-leg with a linnen apron, or the fkins of the facrifices; and they wore crowns of laurel upon their heads. *Danet* in voc. See POPE, *Cycl.*

POPE, in zoology, a name by which the people in many parts of England call the *anas arctica clufii*. See the article DUCK.

POPLAR, *populus*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the amentaceous kind, being compofed of a number of fmall leaves, furnifhed with a great quantity of apices; but thefe are barren. The embryo fruits are produced on thofe trees which produce none of thefe flowers; thefe are fpiked, and confift of many leaves, under which there lies a fort of bell, which contains the embryo feed veffel, which finally becomes a membranaceous pod of a compreffed figure. Thefe are difpofed in a fpiked form, and open into two parts, containing feeds winged with down. To this it is to be added, that the *poplar* has a peculiar and appropriated general appearance, by which it is obvioufly diftinguifhed from the willow. See Tab. 1. of Botany, Clafs 19.

The fpecies of *poplar* enumerated by Mr. Tournefort, are thefe: 1. The common white *poplar*, with large leaves 2. The common white *poplar*, with fmaller leaves. 3. The common black *poplar*. And, 4. The *poplar* with trembling leaves, called the *afpen-tree*. *Tourn.* Inft. p. 592.

The *poplar*, whether black or white, may be eafily propagated, either by layers, cutings, or fuckers, of which the white kind always produces a great many from the root. The beft feafon for the tranfplanting thefe fuckers is in October, when the leaves begin to decay; and they fhould be removed into a nurfery for two or three years, at the end of which time they will have got ftrength enough to be tranfplanted into the places where they are to remain.

When they are to be propagated by cuttings, it is beft to do that in February, cutting off large truncheons of eight or ten foot long; which being thruft down a foot deep in the ground, will take root very quickly, and if the foil be moift, will grow to a confiderable fize in a very few years.

The black *poplar* is not fo eafily raifed from thefe large truncheons, but fhould be planted in cuttings, of about a foot and a half long, planting them a foot deep in the ground. This will grow on almoft any foil; but does much better on a moift one than on any other. They are the fitteft of all trees for raifing a fhade quickly, as they will grow fourteen foot in heighth fometimes in one feafon, and in four or five years will be large trees. *Miller's* Gard. Dict.

POPLAR-*galls*. The black *poplar* is famous among naturalifts for producing a fort of *galls* or protuberances, of various fhapes and fizes, on its leaves and branches, which have been ufually miftaken for the lodgments of worms hatched from the eggs of an ichneumon-fly; but they are in reality produced by the operation of a viviparous infect, called the *puceron*, for the bringing up of its off-fpring. See PUCERON.

Thefe *galls* are of the bladder kind, being ufually fkinned over, and more or lefs hollow within, not woody, as thofe of the oak, &c. They proceed from different parts of the plant, fome from the pedicles of the leaves, and many from the young fhoots. They are very various in figure, fome being roundifh, others oblong, others crooked and contorted in various directions, and fome of them are in the figure of horns, like thofe of the turpentine tree, and of the fame origin.

When any of thefe *galls* are opened at a proper feafon, there is found in them a vaft number of infects of the puceron kind, all the family of one female parent, who formed the bladder or *gall* for their reception: if they are opened a little earlier than this, there is only one, that is the female parent, found in them: and finally, if they are examined later, they are found empty, the young brood having made their efcape out of them; and at this time the ftalks of the leaves are found twifted about and fwelled; and in thefe fwellings, which are a new fort of *gal's*, are found the young pucerons, which had efcaped out of the larger *gall* or bladder, which had ferved for their common home.

Mr. Malpighi obferved thefe fpiral tubercles on the pedicles of the leaves of this tree, and has given a figure of them in his twenty-ninth plate; but he had no knowledge of this animal which occafions them, nor, indeed, any idea of a viviparous creature being at all concerned in the formation of *galls* on vegetables; his whole fyftem being founded upon their being the effect of the eggs of a fly depofited in them: he has therefore defcribed thefe fpiral ones among the reft, as being of the fame origin, and filled with eggs; but if he had accurately examined the bodies themfelves, he would have found them filled with real living infects, not eggs of any kind.

Befides thefe *galls* on the ftalks and pedicles of this tree, there are alfo others found on the leaves themfelves; and thefe are always joined to and prolonged from the middle rib of the leaf, which is properly only the continuation of the pedicle, and feem only to be the middle rib diftended and fwelled, the rib being wanting in the part where they are, on the upper fide of the leaf, and on the under fide there being only a little flit or crack, but with its edges nicely joined in the place of it; and if the leaf be preffed between the fingers, this crack will open wider, and fhew the internal cavity of the *gall* or bladder that appears on the upper fide, and the little pucerons are feen living in it; but as foon as the leaf is left to itfelf again, the edges of this flit clofe, and the creatures find themfelves as well defended from all injuries as before. There is great reafon for thefe little creatures thus hiding themfelves, for they are, when expofed to the view of other infects, fed upon by many little animals; and it is a common thing, on taking one of them out of its cell, and fetting it on the furface of the leaf, to fee a little yellowifh bug immediately come up, and feize upon it, and fuck it to death with its trunk, which is extremely fine, but is eafily introduced into the body of this creature.

The care the pucerons take to hide themfelves, and their young, from thefe enemies, is not, however, always fufficient; for it is a very common thing to find a fmall red infect, of an oblong form, and endued with a very long trunk, lodged in the very cells, and eating them up in their habitations. This is fuppofed by Reaumur to be the bug before mentioned in its nymph ftate, and had doubtlefs been lodged in this place by its parent in the egg, in order to feed upon the young animals.

The pucerons which live upon the poplar have another method of fecuring themfelves from injuries. They have a method of forming a bladder of the very fubftance of the leaf itfelf, and this is very capacious, its cavity being much larger than that of any other kind: this is done by bringing the two edges of the leaf together, fo that the leaf has its whole length, tho' only half its breadth, and the edges are every where faftened together, while the whole fpace within remains free, and is a fit receptacle for the animals. The cavity is much largeft near the rib, and the leaves which are thus folded have not the colour or the glofs of the others; but are covered with a vaft number of little tuberofities of a reddifh colour, and of the bignefs of a pin's head. This is ufually effected while the leaves are young and green, and at firft there are only found a few fmall pucerons in them; by thefe may be feen the true caufe of the joining together of the leaf into a fort of fack or cafe. If two or three of thefe are found, as is very frequent on the under fide of the leaf of this tree, they are always found fixed in their fucking pofture, near the middle rib; and if the upper fide of the leaf be examined, there will be found on it a yellowifh or pale green tubercle, juft oppofite to every one of the infects. Thefe tubercles are fo many fmall bladders or leaf *galls*; and as they continually increafe in fize, and by that increafe force out the middle part of the leaf on which they are placed into a fwelling upwards, the confequence is, the drawing together of the edges, fo as to form a cafe or bag, of which the outfide of the leaf makes the external covering, and the infide the lining. The regularity of the placing of thefe tubercles in the center of the leaf is the reafon of the edges falling evenly together; and fometimes, when the tubercles are lefs regularly fituated, the joinings have feveral empty or open fpaces between them. Thefe two or three firft tubercles are afterwards furrounded by a vaft number of new ones, which are the effects of the progeny of the firft obferved infects; and thus the generality of the larger leaf or bladder-*galls* are formed, as well on the *poplar* as on the elm, the apple, and the other trees on which they are fo frequently found.

The pucerons which are found inhabiting the leaves of the *poplar* thus curled up, are of the fame fhape and figure with thofe of the other parts of the fame tree, and probably are the very fame fpecies; tho' fome fuppofe them different from the

dif-

different manner of their working. *Reaumur*'s Hift. Inf. Vol. VI. p. 39, feq.

POPLITÆUS, *(Cycl.)* a fmall mufcle, obliquely pyramidal, fituated under the ham. It is fixed above, by a ftrong narrow tendon, to the outer edge of the inner condyle of the os femoris, and to the neighbouring pofterior ligament of the joint; from thence it runs obliquely downward, under the inner condyle of the os femoris; its flat and pretty thick flefhy body increafing gradually in breadth, till it is fixed in the backfide of the head of the tibia all the way to the oblique line obfervable on that fide. *Winflow*'s Anat. p. 216.

POPPY, *(Cycl.)* PAPAVER, in botany. See PAPAVER.

We have many fpecies of this plant cultivated in gardens for the beauty of the flowers. They are all eafily propagated by fowing the feeds in autumn. When the young plants come up, they are to be cleared from weeds, and thinned to a proper diftance by pulling fome up where they ftand too thick; for they never thrive well if they are tranfplanted. They are to be left, according to their fizes, at fix, eight, or ten inches diftance.

They are very fhowy flowers, and make a fplendid appearance in gardens; but they are but of fhort duration, and are of an offenfive fmell, which makes them lefs valued at prefent than they have been.

Some fow thefe plants in fpring, but it is not fo well; becaufe they then have not time to get ftrength before autumn, when they are to flower; and for that reafon thofe fown in fpring ufually flower weakly. *Miller*'s Gard. Dict.

Red-POPPY. The common wild red *poppy* is one of the moft troublefome and mifchievous weeds the farmers are plagued with among their corn, and it is the moft difficult to thoroughly deftroy of almoft any other. Its feed will lie a long time in land unploughed, without ever fhooting; but they will be fure to grow with the firft crop of corn. Mr. Tull gives an inftance of the feeds of this plant being buried four and twenty years in a field of faint-foin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, tho' they had lain dormant fo long before. *Tull*'s Horfehoing Hufbandry.

It has been the general opinion of authors, that the narcotic quality of the *red poppy* lay in its flowers; but Mr. Boulduc, in his courfe of experiments for the finding out an European plant which fhould yield us a juice of the nature of the opium of the Eaft, without its bad effects, found that the virtue of this plant, which is very great, lay much more in the heads than the flowers; and from four ounces of thefe heads, while frefh and green, he obtained five drachms of a folid extract, of the nature of opium, two, three, or four grains of which were a full dofe; and which poffeffed the virtues of opium, and might be given with great fuccefs and fafety in obftinate coughs and other fuch cafes. Hift. Acad. Par. 1712.

It is faid, that the extract of Britifh *poppies* is, in fome cafes, preferable to the opium brought from Turkey. We have, in the medical effays of Edinburgh, the method of preparing an extract and fyrup of *poppies*, by Mr. Arnot. See Vol. 5. Art. 11.

Yellow POPPY. The yellow horned *poppy*, called by authors *papaver corniculatum luteum*, is one of thofe vegetable poifons of our own growth, which may be very mifchievous by their not being generally known, or fufpected to be fo. We have an account of the effects of this plant in the philofophical tranfactions, in an inftance of a family in Cornwall, who eat of a pye made of the roots of this inftead of thofe of eryngo, or fea-holly, which it is the cuftom of the poorer people there to make into a coarfe fort of pye for their food.

The man of the houfe, on eating of this pye while hot, was feized immediately with a violent delirium, one effect of which was his thinking every thing he faw of a yellow colour, and taking every utenfil of the houfe to be made of gold. The man and maid fervant eat of the pye after their mafter, and were foon after as mad as he, coming into the room where his friends were attending him, ftripped naked, and dancing together. Thefe people alfo took every thing they faw to be gold; and a child in the cradle, to whom a fmall piece of the pye had been given, was thrown into a drowfy diforder, and convulfed about the mouth; but, after a few days, it recovered.

The grown people were all feized with moft violent purgings, and by that means efcaped, after being miferably worn down by this complaint.

The fymptom of fuppofing every thing gold, which ran through the whole family, and went even fo far as to the fuppofing their ftools gold, and ordering them to be faved, may poffibly be in fome meafure owing to the idea they had of the plant whofe roots they had been poifoned by; its flowers being as large as a rofe, and of a fine yellow, and the juice of the whole plant being alfo yellow. Phil. Tranf. N°. 242.

Horned POPPY. See GLAUCIUM.

POPPY-*feeds*. The *poppy-feed* is of a more delicious tafte than fweet almonds; it is oily and farinaceous. Dr. Alfton fays, he has eaten large quantities of the black as well as the white feed, and never found it fomniferous or noxious. See Med. Eff. Edinb. Vol. 5. Art. 12.

Thefe feeds are ufed in food in fome places, as is their expreffed oil, which is as wholefome as olive oil. Vid. Matthiol. p. 746. *Geoffr.* Mat. Med. Vol. 2. p. 713.

POPULAGO, *marfh-marygold*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the rofaceous kind, being compofed of feveral petals arranged in a circular form; from its center arifes a piftil, which afterwards becomes a membranaceous fruit, confifting as it were of feveral thin capfules collected into a head. Thefe capfules all bend a little downwards, and contain oblong feeds.

The fpecies of *populago*, enumerated by Mr. Tournefort, are thefe: 1. The common large flowered *populago*. 2. The fmaller flowered *populago*. And, 3. The *populago* with double flowers. *Tourn.* Inft. p. 273.

POPULARIA, among the Romans, were fteps or places where the people fat and beheld the games and horfe-races. *Pitifc.* Lex. Ant. in voc.

PORCALA, a name given by fome of the later Latin writers to the herb purflain, as if it had its name from being loved by the hogs.

PORCELAIN *(Cycl.)*—The moft juft and regular idea we can form of the *porcelain* or china-ware is, that it is an half vitrified fubftance or manufacture, in a middle ftate between the common baked earthen ware of our vulgar manufactures, and true glafs. This is the effential and diftinctive character of *porcelain*, and it is only by confidering it in this light, that we are to hope to arrive at the perfect art of imitating it in Europe.

This attempt is to be made on thefe principles in two different manners: the one by finding fome appropriated matter on which fire acts with more than ordinary ftrength in the time of its paffing from the common baked ftate of earthen ware into that of glafs. The other is, to compofe a pafte of two fubftances reduced to powder; the one of which fhall be of force to refift a very violent fire, fo as not to become vitrified in it; and the other a matter very eafily vitrifiable. In the firft cafe, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and in the other, the compound mafs is to remain in the furnace till the one fubftance, which is the more eafily vitrifiable, is truly vitrified; and being then taken out, the whole will be what *porcelain* is, a fubftance in part vitrified, but not wholly fo.

The firft method is that by which the European *porcelain* has generally been made, and tho' that of St. Cloud, and fome other places, has been very beautiful, yet it is always eafy to diftinguifh even the fineft of it from the china-ware, and the nature of the two fubftances appears evidently different: thefe owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a very little longer continuance would have made them perfect glafs; on the contrary, the china-ware being made of a pafte, part of which is made of a fubftance in itfelf fcarce poffible to be vitrified, bears the fire in a yet much more intenfe degree than ours, and is in no danger of running wholly into glafs from it.

The two fubftances ufed by the Chinefe are well known by the names of *petunfe* and *kaolin*, and on examining thefe it appears very evident, that we have in Europe the very fame fubftances, or at leaft fubftances of the very fame nature, and capable of being wrought into a *porcelain* equally beautiful and fine. Mem. Acad. Scienc. Par. 1739. See the articles KAOLIN and PETUNSE.

Thefe are the two different femi-vitrifications, on one or other of which all the European manufactures have hitherto been founded; and it is eafy from the knowledge of thefe principles to determine, on breaking a piece of the china of any of our manufactures, by which of the two proceffes it is made. If it is made by fiezing the half-vitrified mafs of a fubftance which would foon after have been wholly vitrified, then the putting it in a crucible, into an equal degree of fire, will foon turn it wholly into glafs. This is the cafe of moft of our European *porcelain*; but if it be made of two ingredients, the one of which is not vitrifiable, or at leaft not by fuch fires, then the matter will melt, but will not vitrify: this is the cafe with the Chinefe *porcelain*, which, if kept in fufion a long time, yet when cold is china-ware ftill; fo that this is evidently made of two fuch different ingredients.

Befides thefe methods, there is yet another, of late invention, which makes a very beautiful china; and which, if it does not afford veffels equal to thofe of China, yet will afford them nearly approaching to thofe, and at a confiderable fmaller price. This method confifts in reducing glafs to china. See the article GLASS-*porcelain*.

The fine deep blue of the old *porcelain*-ware of China, is much valued by the curious; and it is much lamented, that the fame colour is not ufed at this time. The art feems at prefent to be loft; but perhaps it might be recovered by trials. It is certain that the Chinefe have cobalt among them, and very probably they ufed a blue colour prepared from this before they had any commerce with us: notwithftanding all the con-

conjectures about their materials for colouring, this seems the most probable substance; and there is a way of preparing a colour from this, much superior to that now in use, which we call smalt.

Cobalt is a mineral containing arsenic and a blue vitrifiable earth. The common way of preparing smalt is, by roasting this cobalt in a reverberatory fire. This disposes it to vitrify, and drives off the arsenic it contains in fumes, which collecting at the top, form true flowers of arsenic. It is very certain, however, from experiments, that if this arsenic could be preserved in the cobalt, the smalt would be of a much finer colour; for there are some kinds of cobalt which yield smalt without previous roasting; and as the arsenic is in a great measure contained in these, the smalts are much finer coloured. Arsenic added to smalt, while in fusion, greatly exalts its colour also; and there is a way of procuring smalt from cobalt without fire, only by dissolving it in an acid, and precipitating that solution with oil of tartar. The smalt thus precipitated to the bottom, is of a much finer colour than any prepared by fire; but it is much more expensive, and prepared in less quantity It is very possible, that the Chinese might have the art of making this kind of smalt before they knew us, and that to this was owing the fine blue of their *porcelain* ware: but when we trafficked with them, and they purchased smalt so much cheaper of us than they could make it themselves, they naturally discontinued the manufacture of their own finer kind, without considering how greatly inferior the colour was which the other yielded. If this be the case, it will be easy to revive this art, and the adding the true old china blue to our European manufactures, in imitation of *porcelain*, may give them a value which they have not at present.

The Chinese had once a method of painting the figures of fishes and other things on the insides of their vessels, in such a manner that they did not appear till the vessel was filled with water, or some other clear liquor. They called this sort of china-ware *kiatsim*, that is to say, the concealed blue china. The art is now in a great measure lost; but there may be some guess made as to the manner in which it might be done at this time. The vessels which are to be made in this manner, must be very thin: the colour must be laid on in form of the fish or other animals or figures, on the inside, after the vessel has been once baked. After this colour has had time to dry, the inside of the vessel must have a second coat of the same earth, or stone-ware, of which the vessel is made; and over this a varnish of the common kind. The consequence of this will be, that the figures of the fish, in a very strong colour, will be buried between two coats of the ware, which together form a compleat vessel. The outside is then to be ground down almost to the figures, and when they begin to appear, a new coat of the varnish must be laid over this. The figures will then be obscure, and scarce, if at all perceivable; but on filling the vessel with water, the transparence of the sides will be taken off, and the liquor will make a sort of foil behind, which will throw out the figures of the fish. This might be done in any ware tolerably clear and transparent. The *porcelain* of China would succeed best with it; but the pains and nicety required are too great, and all the attempts lately made by them have miscarried. See the article STAINING of *porcelain*.

The Chinese make a great variety of figures on the surfaces of the vases of white china-ware, and there is one kind of this greatly in esteem among them, in which there are flowers and other figures; yet the surface is quite smooth, and the substance extremely thin. The manner of making it is this: they first form the vessel of the finest materials, as thin as they can; then, when they have polished it inside and out at the wheel, they put into it a stamp of its own shape, but cut with all these figures: they press this down so firmly on the yet moist vessel, that the impression is received in a very perfect manner; and if the shape of the vessel be at all hurt, they take it to the wheel again to restore it. They then finish it with the knife and scissars; and when they have made it as perfect as can be, they cover it with the fine white varnish within and without. This fills up all the cavities of the impression, and gives a perfectly smooth and even surface; yet the thickness of this varnish in the traces of the figures gives it a different white, and the whole figures are as finely and accurately seen, as if painted on the outside. This is an artifice that might easily be brought to bear among us, and several of our finer wares would make a pretty figure with it.

There is a current opinion among the Chinese themselves, that the *porcelain*-ware of former times was greatly superior to that which they make at present; and that the burying china in the earth for a long time, adds to its beauty; but all this is founded on error. The truth is, that our merchants beat down the price of the ware, and thereby compel them to make a worse kind in general; but they are able to do as fine things now as ever What gave birth to the opinion, that burying *porcelain*-ware made it good, was, that finer pieces than ordinary are sometimes found buried. These are all precious vases; which the possessors buried by way of security in the times of civil war; and it is no wonder, that there are none but of the finest kind found buried on these occasions. Observ. sur les Coutum. de l'Asie.

PORCELLANA, in natural history, the *porcelain-shell*, or *concha venerea*, the name of a genus of shell fish, the characters of which are these: they are of the univalve kind, and have for their mouth a long and narrow slit, dentated on each side, and are of a conglobated, oblong, gibbose, or umbonated form.

This genus of shells originally had the name *porcellana* and *concha venerea* from the resemblance of its mouth to the *pudendum muliebre*, called by some of the Roman writers, *porculus* and *porcellus*, and always alluded to under the word *Venus*. We have of late so far misunderstood the name as to suppose it derived of the word *porcelain*, from an imagination, that the Chinese porcelain-ware was made of it. Gesner has fallen into the opinion, and Aldrovand seems to have been mistaken in regard to its other name, *concha venerea*, supposing it so called because of its beauty, and therefore sacred to Venus. Rondeletius calls it the *remora Mutiani*; and the murex of the same author. *Aldrovand* de Test. L. 3. p. 352. *Gesner*. *Rondelet*. de Test. L. 2. p. 101.

The name *concha venerea* may be apt to create confusion, because there is another shell of a very different kind, a bivalve, called *concha veneris*. This genus is therefore much better distinguished by the name *porcellana*. There is a prodigious difference among the species of this genus; some are heavy, others very light; some have the mouth placed in a longitudinal, others in a transverse direction. The gibbous *porcelain* is a very remarkable species, as is also the egg-*porcelain*, which has two buttons at the extremities; and the egg-*porcelain* called the *navel* is not less remarkable than these; this has, instead of a button, a long beak at each end.

The mouth of the *porcelain* must be narrow and oblong; this is the great characteristic, and is usually dentated either on both sides or on one.

The species of *porcelain* are so numerous, that it may be proper, in the enumeration of them, to arrange them under some regular heads. See Tab of Shells, N°. 16.

Some *porcelaines* are conglobated, and thick; of these the cabinets of the curious afford us the following species: 1. The map-*porcelain*, so called from its lineations, resembling the strokes of a map. 2. The lettered or Arabian *porcelain*: this is supposed in its lineations to bear some resemblance to Arabic characters. 3. The tyger's skin *porcelain*. 4. The serpent's skin *porcelain*. 5. The sea-louse *porcelain*. 6. The millepede *porcelain*, 7. The punctuated *porcelain*. 8. The grey *porcelain*. 9. The Chinese *porcelain*. 10. The *porcelain* whose end terminates in a spire; or the violet *porcelain*: this is but the former species with its outer coat taken off. 11. The reddish *porcelain*. 12. The variegated *porcelain*. 13. The tortoise-shell *porcelain*. 14. The guttated *porcelain*. 15. The *porcelain* with its middle divided into four zones. 16. The blue oval *porcelain*.

Some *porcelains* are thin, and of a pyriform figure. Of these we have the following: 1. The pear-*porcelain*, with an arched mouth, and variegated with yellow spots. 2. The pear-*porcelain*, with an arcuated mouth and two zones. 3. The egg-*porcelain*, with numbers of small protuberances, or obtuse umbos: this is called by some writers *ovum Rumphii*, or Rumphius's egg. 4. The cloth-web *porcelain*. 5. The oblong and thick *porcelain*. 6. The great Argus *porcelain*, so called from its being variegated with round spots, resembling eyes. 7. The lesser Argus *porcelain*. 8. The pseudo-argus, or bastard-eye *porcelain*. 9. The leveret *porcelain*. 10. The greenish small-pox *porcelain*. 11. The whitish *porcelain*, with rough protuberances. 12. The millepede *porcelain*. 13. The mouse *porcelain*. 14. The mole-*porcelain*. 15. The yellow *porcelain*, with four red zones. 16. The brown *porcelain*, with four yellow zones 17. The Panama *porcelain*, with amathystine circular streaks. 18. The green spotted *porcelain*. 19. The virgated agate *porcelain*. 20. The blue *porcelain*. 21. The blue spotted *porcelain*.

Some of the *porcelains* are gibbous. Of these we have the following species: 1. The milky *porcelain*, with rose-coloured protuberances and a dentated lip. 2. The white gibbose *porcelain*, with a smooth lip and no tubercles. 3. The yellow *porcelain*, with a smooth lip and no tubercles. 4. The *porcelain* called *Congo money* and *Guinea money*: this has a dentated mouth, and has six protuberances on the back. 5. The great gibbous *porcelain*. Hist. Nat Eclairc. p. 308.

PORCELLIONES, in the materia medica, a name given by some to the millepedes.

PORCELLO, in the glass trade, the instrument with which the workman, after having made the opening for the bowl of a drinking glass or other such vessel, with his passage, widens and renders it more capacious at pleasure. *Neri's* Art of Glass, p. 247.

PORCELLUS *Cassoviensis*, in medicine, the name of a disease to which the people of Hungary and Poland are very subject. It is a hard tumour of the belly, attended with wind and violent pains. It is truly an infarction of the spleen, and is to be cured by aperitives. Phil Trans. N°. 243. See SPLEEN.

PORCELLUS *Indicus*, in zoology, a name given by authors to the animal called with us the *Guinea pig*.

It is a creature properly of the rat kind, and is not improperly called by Mr. Ray *mus Americanus et Guinienfis porcelli pilis et voce*: the American or Guinea rat, with the hair and voice of a pig; tho' the fame author feems to doubt, whether it has not fomething of the rabbit kind in it, by adding after the word *mus*, that of *cuniculus*.

It is fmaller than the rabbit, and has a fhorter and thicker body; its ears are roundifh, low, thin, pellucid, and very wide open, and are almoft fmooth; and are obferved to be very nearly as large in the new brought forth creatures as in the full grown.

Its nofe and beard are very much like thofe of the hare; the long hairs which ferve for whifkers being difpofed in much the fame manner, and its upper lip is like that of the rabbit. It has no tail; its teeth are difpofed exactly as in the rat kind, and its hairs and grunting voice are wholly like thofe of the pig.

It is fometimes all over white, fometimes all over of a reddifh tawney; but moft frequently it is mottled with large fpots of both. Its fore feet have four claws, its hinder ones only three, of which the middle one is much longer than the others. It fits often upon its buttocks, in the manner of the rabbit, but it does not walk in the leaping manner of the rabbit kind; but as the hog, by fetting one foot before the other; and in walking bears upon the heel in the manner of the bear. It does not burrow in the earth; it brings forth fix, feven, or eight young ones at a time; and thefe are not blind at firft, as in the rabbit. It feeds on vegetables, and its flefh is very well tafted, and much refembles that of the hog. *Ray*'s Syn. Quad. p. 22?.

PORCO, a name by which fome authors have called the fifh more ufually known by the name of *caprifcus*, fuppofed to be the *porcus* of Pliny. *Willughby*'s Hift. Pifc. p. 153. See the article CAPRISCUS.

PORCUPINE, *hiftrix*, in zoology. See HISTRIX.

American PORCUPINE, *cuanda*, in zoology, the name of a fpecies of *porcupine* very different from the European kind.

It is of the fize of the larger monkeys, and is covered all over, except on its nofe, the lower part of its legs, and the extremity of its tail, with fpines of two or three inches long, and has no other hair but thefe. Thefe are yellowifh for that half which is next the body, thence they are of a deep blackifh brown, and at the very extremity they are white: they are hollow in the manner of quills; and Hernandez affirms, that the creature has a power of throwing them from its body to a confiderable diftance. The body is about a foot long, the tail fomewhat longer than that, and its farther half covered thinly with hairs much refembling hog's briftles. The ears are fmall, and are hid by the fpines which cover the head. It has two long teeth in each jaw before; the noftrils are very wide, the eyes round, prominent, and very bright and fparkling; the feet are like thofe of the monkey kind, and divided into four toes. See Tab. of Quadrupeds, N°. 15.

It climbs trees, but flowly and with difficulty, for want of a heel or hinder toe. It ufually twifts its tail about a bough, to keep it fafe from falling. It makes a grunting like that of a hog. It feeds on poultry, and its flefh is very well tafted. *Ray*'s Syn. Quad. p. 208.

PORCUS *aculeatus*, in zoology, the name of an animal, of which there are two fpecies, both of the porcupine kind; the one with a fhort, the other with a long tail. Each of them have alfo five toes on each foot, in which they differ from the European porcupines, which have but four. *Seba*. Vol. I. p. 81. and p. 84.

PORCUS *fluviatilis*, in ichthyology, a name given by the old Latin authors to the fifh we at this time call the *cornua* and *aurota*, and in Englifh the *ruffe*. It is a fpecies of the perca or pearch kind, and is diftinguifhed by Artedi by the name of the *pearch* with only one fin on the back, and with the cavernous head. See Tab. of Fifhes, N°. 20.

PORCUS *Guinienfis*, in zoology, the name of the Guinea hog. This creature is of the fame fhape and make with our hog, and of a reddifh tawney colour. Its head, however, is fomewhat more depreffed than in our kind, and its ears longer, and running into narrow points. Its tail is naked; but fo long, that it reaches almoft to its heels. Its hair is all fhort and fhining. It has no briftles on the back, but only near the rump; and on the fhoulders the hair is a little longer than elfewhere. It is a tame domeftic creature. *Ray*'s Syn. Quad. p. 96.

PORELLA, in botany, the name of a genus of moffes, the characters of which are thefe: the capfules contain a powder like thofe of the other moffes; and they have neither operculum, calyptra, nor pedicle; and their manner of fhedding their powder is not by feparating into two parts, like thofe of the felago and lycopodium, but by opening into feveral holes on all fides. See Tab. of Moffes, N°. 17.

Of this genus of moffes there is only one known fpecies; this is called by Dillenius the bluntly pinnated *porella*, and grows in wet places in Virginia, Penfilvania, Maryland, and other parts of North America. *Dillen*. Hift. Mufc. p. 459.

PORFILIGON, a word ufed by fome of the chemical writers to exprefs the fquammæ martis, or the fcales of iron which fly off in the fmith's hammering of it.

POROCELE, a word ufed by chirurgical writers for a callous hernia.

POROMPHALON, a word ufed by Hippocrates to exprefs a callous concretion, or a fort of tophus formed in the region of the navel.

POROTICKS, a term ufed by the antients for fuch medicines as would confume callufes.

PORPESSE, an Englifh name given indifcriminately to two different fifhes, the phocæna and the dolphin.

Artedi, who has been very careful in bringing together the fynonyma of authors, tells us, that this is properly the Englifh name only of that fpecies of the dolphin, the characters of which, according to his fyftem, is, that the body is almoft of a conic form, the back broad, and the body fubacute. This fpecies is the phocæna of Ariftotle, and the tirfio or turfio of Pliny and Rondeletius. Schoneveldt calls it the fmall northern or oriental *dolphin*, and the Swedes the *marfuin*. See the article DELPHINUS.

We have from Dr. Lifter an account of the tooth of this creature, after death, giving an envenomed wound. The accident happened to the Doctor himfelf, and he relates it thus: in diffecting a *porpeffe*, which had been four days dead, he fcratched accidentally the infide of one of his fingers; but that not fo deep as to fetch blood, or to occafion any great pain. He difregarded the accident; but at the end of four days the whole joint of the finger became tumid, and inflamed foon after the whole finger. After this the malady increafed, and in fpite of the affiftance of furgeons, the four next fingers were in four days more affected; and after thefe the whole hand up to the wrift, and the pain became violent. This was firft abated by the following fomentations: frog fpawn-water, fix ounces; bole armeniac, an ounce and half; white vitriol, four ounces. And afterwards this: burnt white vitriol and bole armeniac, of each four ounces; camphor, an ounce; and common water, a gallon. The wafhing the hand continually with thefe, took off the pain; and after this the unguentum nutritum, and a plaifter of diaphalma over the whole hand, perfected the cure. The Doctor obferves, that befide the blue look of the parts, which fufficiently indicated the poifon, there was a continual itching and burning heat, which was conftant day and night. The fkin of the whole hand and fingers came off, and the fingers did not fo far recover, as to have their full ufe for feveral months after. Phil. Tranf. N°. 231.

The fins of this fifh are cartilaginous and flexible, not fharp or prickly, as the antients have reprefented them. There is only one fin on the back, which is placed fomewhat below the middle: on the belly there is only one pair of fins; and the tail is formed into the figure of a crefcent by its forkednefs; and this tail lies parallel to the horrizon, when the fifh fwims, in the fame manner that the tails of all the other cetaceous fifhes do; whereas the tails of all other fifh ftand perpendicular to the horizon. The great contrivance of nature in this pofition of the tail in thefe fifhes is, that it may fupply the place of the hinder pair of belly-fins in other fifh, thofe of the cetaceous kind having none fuch. Thefe fins in other fifh ferve to balance the body, and keep it under water, and anfwers alfo in many refpects to the hinder legs of a quadruped; and hence we fee, that thofe fifh which have long bodies, and have not this hinder pair of fins, nor the horizontal tail, cannot fufpend themfelves quietly in the water, but are forced to keep groveling at the bottom. This is the cafe of eels, and all other fifh of that kind. The ufe of refpiration being as neceffary to the *porpeffe* as to quadrupeds, and it wanting this pair of hinder fins, to poize or elevate itfelf with, nature has abundantly provided againft the mifchiefs that would attend that defect, by giving it this tranfverfe tail; by a fudden jerk of which it can in a moment throw itfelf up to the furface from the deep water. The whale, and all the cetaceous fifhes requiring the ufe of refpiration, have alfo this manner of raifing their unweildy bodies allotted them by nature, inftead of the hinder pair of fins, which muft have been inconveniently large to be capable of this office.

The blood of the *porpeffe* is as warm to the touch as that of quadrupeds, and the blubber, or fat, which lies in great quantity under the fkin, covering the mufcular flefh of the back and fides, is to keep up the natural heat, and prevent the cold of the fea water from chilling the circulating fluid.

The ftomach of this fifh is of a very ftrange make; it is divided into two large bags, and has feveral other fmaller ones annexed to them. The food of the fifh feems to befpeak its living at the bottom of the water; for the common matter found in its ftomach, is the remains of fifh that live in or on the bottom. The young *porpeffes* are generally found to feed on the ammodytæ, or fand-eels.

The kidneys in this fifh are large, and adhere clofely to the back; and the urinary bladder is oblong, but very fmall in proportion to the fize of the animal. The penis in the male is long and flender, and has a very flender and fharp glans. This part does not appear externally; but lies buried in its fheath in the body, and is there doubled up in the fhape of the letter S; and the tefticles lie within the cavity of the abdomen, as they do in the hedge-hog. The diaphragm is mufcular, as in quadrupeds. The heart is large, included in a pericardium,

ricardium, and has two ventricles; and this part, as well as the lungs, agree in all refpects with thofe of quadrupeds. The fifh having no neck, the larynx is confequently very fhort. The pipe in the head, thro' which thefe fort of fifhes draw in their breath, and fpout out water, lies before the brain; it terminates outwardly in one hole, but it is within divided into two parts by a bony feptum, fo as to reprefent two noftrils; but at its lower end it again becomes one hole, and opens into the mouth by a common orifice furnifhed with a very ftrong fphincter mufcle, by means of which it may be fhut and opened at pleafure. Above this fphincter, the fides of the pipe are lined with a glandulous flefh; from which when preffed, a glutinous liquor is forced out of certain little holes in it into the infide of the pipe: above the noftrils is a ftrong valve or membrane, which ferves to ftop the pipe at pleafure, and prevent any water from getting into it, but when the fifh requires it within. The fiftula are fix blind holes, having no outlet, four tending toward the fnout, and two placed above the valve, which ftops the noftrils, and two beneath it; and two tending toward the brain, having a long and narrow cavity which feems intended for the ufe of fmelling, tho', on opening the brain, no fuch olfactory nerves or proceffus mamillaris, as other animals are furnifhed with for this purpofe, are to be found. The eyes are fmall, and the fnout is very long, and furnifhed with ftrong mufcles; the ufe of thefe is to enable it to root up the fand and dirt at the bottom of the fea, and feed on the fand-eels and other creatures it finds buried in it. The brain is large, and refembles that of man, and probably it has been an obfervation of this that has given occafion to the opinion of this animal having fo great a fhare of will and underftanding, and has given rife to the ftory of Herodotus, that Arion was carried to fhore on the back of one; and that of Pliny the elder, of one of thefe fifh fo fond of a certain boy, that he ufed to carry him daily from Baiæ to Puteoli, acrofs the fea to fchool, and wait to carry him back again at a certain time. Pliny the younger gives us alfo a ftory of this kind in his epiftles.

The teeth of the *porpefs* are in each jaw forty-eight in number; they are fhort and blunt, and refemble fo many pegs. The antients, particularly Ariftotle, have faid that the tongue of the *porpefs* or dolphin is tied down faft to the lower jaw, all along the middle. Rondeletius has difputed and contradicted this obfervation; but Mr. Ray proves it to be true, and that the modern author is in an error. Ariftotle denies this fifh ear-holes, and experience fhews that he is in the right; nor has it any noftrils, except thofe within the fiftula. The breaft bone is remarkably fmall. The name *porpefs* is given it becaufe of its refembling a hog; which it does in the fnout, the fat, the vifcera, and many other particulars. Phil. Tranf. Nº 74.

PORPHYRIO, in zoology, the name of a bird figured and defcribed by all the natural hiftorians from one another, but which, it feems, none of them ever faw; and there is fome room to doubt whether there be in nature any fuch bird. According to the accounts we have of it, it appears to be of the gallinula or moor-hen kind, and is all over of a fine deep blue, only the middle of the tail is at the extremity of a greyifh white. Its legs and feet are of a fine fhining purple. There have been fome fabulous things related of it, as its having five toes on each foot, and the like; but if there be any fuch creature, it feems to be a moor-hen of thefe remarkable colours. *Gefner* de Avib. *Ray*'s Ornithol. p. 238.

PORPHYRIO *Americanus*, in zoology, a name by which fome have called the *quachilto*, a very beautiful fpecies of Brafilian moor-hen. See the article QUACHILTO.

PORPHYRY, *(Cycl.) porphyrita*, in natural hiftory, the name of a genus of foffils generally, but improperly, added to the marbles, and called by us *porphyry*. They are ftones of a plain uniform mafs, fpotted or veined, with feparate concretions of great hardnefs, giving fire with fteel, not fermenting with acids, and very flowly and difficultly calcining in a ftrong fire. *Hill*'s Hift. of Foff. p. 494.

Of this genus there are only three known fpecies: 1. The purple kind, commonly known by the name of *porphyry*, among the workmen. 2. The hard red-lead-coloured kind, variegated with black, white, and green. And 3. The very hard flefh-coloured one, variegated with white, green, and black.

The *purple porphyry* is a fubftance which has been well known, and highly efteemed in all ages of the world. It has its name from the Greek πορφύρος, purple, as that remarkable colour always afforded a very obvious diftinction for it, from the other kinds. It is of an extreme firm and compact ftructure, remarkably heavy, and of a fine ftrong purple, variegated more or lefs with pale red, and white, and with a fmall number of little, and generally difregarded black flaky fpecks. Its purple is of all degrees, from the deep tinge of the violet to a pure claret colour; and its variegations are ufually difpofed in fmall fpots, ufually fmall and difunited, but fometimes running into one another, and making large blotches. It is very difficultly cut, becaufe of its very great hardnefs; but is capable of a very fine polifh. It is found in great quantities in Egypt; and we find was had thence alfo in very early times. It ferves us for ftones for the apothecaries and colourmen, to grind or levigate their powders on, and on any other occafion where great hardnefs is required.

The *red-coloured porphyry* is alfo an extremely beautiful and valuable fubftance, but is hitherto unknown among our lapidaries. It has the hardnefs, and all the other characters of the purple *phorphiry*, and greatly exceeds it in the variety of its colours. Its ground is exactly of the bright fine red of our minium or red lead, but is fomewhat deeper or paler in the different parts of the mafs: this is beautifully veined with green, in broad and regular lines; there are alfo fome confiderably narrow, and among thefe feveral perfectly white ftreaks, and a multitude of fmall black fpecks. It is of extreme hardnefs, and capable of a polifh equal to that of the femi-pellucid gems.

It is found in great plenty in the ifland of Minorca, but has never yet been regarded as a ftone worth importing into England.

The *flefh-coloured porphyry*. This is another very little known, but extremely beautiful ftone: it is of an irregular, but very compact and firm texture, and of a pale flefh colour, often approaching to white, and variegated with black, green, and white in large blotches, from half an inch to an inch broad; and fometimes, tho' very feldom, difpofed in regular veins. It appears very livid and gloffy where frefh broken, and is capable of an extremely elegant polifh; and is fo very tranfparent, efpecially in its green parts, that when polifhed one may fee deep into its fubftance. It is found in immenfe ftrata, in Arabia Petræa, and in upper Egypt, and in detached nodules is common to almoft all parts of the world: Germany abounds with them; and we have of them in many parts of England and Ireland. They are found in many places on our fhores, and in fome parts of Devonfhire far from the fea. *Hill*'s Hift. of Foff. p. 494 to 498.

Mr. Boyle tells us, that he caufed *porphyry* to be cut by means of emery, fteel faws, and water. He obferves, that in his time, the workmen in England were ignorant of the manner of working upon *porphyry*, and that none of them would undertake to cut or polifh it. See Works abr. Vol. I. p. 111.

PORPHYRY-*fhell*, in natural hiftory, a name given by authors to a fpecies of fea-fhell of the *purpura* kind, with a fhort clavicle and beak. See PURPURA.

PORPITES, the *hair button-ftone*, in natural hiftory, a name given by authors to a fmall fpecies of foffile coral; which is ufually of a rounded figure confiderably flatted, and ftriated from the center every way to the circumference. Thefe are of different fizes, and of different colours, as greyifh, whitifh, brownifh, or bluifh, and are ufually found immerfed in ftone. See Tab. of Foff. Clafs 7. and *Hill*'s Hift. of Foff. p. 641.

PORRUM, the *leek*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the lilliaceous kind, being compofed of fix petals, and of a bell-like fhape. The piftil which ftands in the middle of this flower, finally becomes a roundifh fruit divided into three cells, and containing roundifh feeds. To this it may be added, that the ftamina are broad, and are terminated by three filaments, the middle one having an apex. The flowers alfo are ufually collected into round heads, and the roots are long, cylindric, and tunicated, the feveral crufts often running up into flat or hollowed leaves.

The fpecies of *leek*, enumerated by Mr. Tournefort, are thefe: 1. The common headed *leek*. 2 The *leek* with variegated leaves, elegantly ftreaked like thofe of the painted grafs. 3. The broad-leaved fectile *leek*. 4. The wild vineyard *leek*. 5. The double-headed wild *leek*. And 6. The vitigineous wild *leek* of Gerrard. *Tourn*. Inft. p. 382

PORT *(Cycl.)*—PORT-*laft*, in a fhip, the fame as the gunwale; therefore they fay a yard is down a *port-laft*, when it lies down on the deck.

PORT-*ropes*, in a fhip. See ROPES.

PORTABLE *laboratory*. See LABORATORY.

PORTE-*etrier*, in the manege. See STIRRUP.

PORTEGLO, in the glafs trade, the inftrument with which the founder, or conciator, fcums the glafs while melting. *Neri*'s Art of Glafs, p 241.

PORTER *(Cycl.)*—PORTER, in the manege, fignifies to direct or pufh on a horfe at pleafure; whether forewards or upon turns, &c.

PORTERAGE, a kind of duty paid at the *cuftom-houfe*, to thofe who attend the water fide, and belong to the package-office. Thefe *porters* have tables fet up, afcertaining their dues for landing of ftranger's goods, and for fhipping out the fame. Merch. Dict

PORTISCULUS, among the Romans, an officer who had the direction of the rowers in a galley. He was otherwife called *paufarius* and *hortator remigum*. *Pitifc*. Lex. Ant. in voc. See PAUSARIUS and HORTATOR

PORTIUS *pifcis*, in zoology, a name given by fome to a fifh called by others the *mugil ater*, or black mullet. It is a very fcarce fifh, much refembling the common mullet in fhape, but all over of a fine black, and having feveral lines of a deeper black than the reft, running longitudinally from the gills to the tail. It has a very wide mouth, and has feven or eight prickles on the back, feparate from one another, and joined into a fin by a membrane in the ufual way; thefe are placed immediately before the back fin. *Willughby*'s Hift. Pifc. p. 276.

PORTOISE, aboard a ſhip, is the ſame with *port-laſt*, or the *gun wale*; and as they ſay *the yard is down a port laſt*, when it lies down on the deck, ſo for a ſhip *to ride a portoiſe*, is to ride with her *yard a port-laſt*, or ſtruck down to the deck.

PORTORARIUM, in anatomy, a name given by ſome authors to the duodenum.

PORTULACA, *purſelain*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is roſaceous, or compoſed of ſeveral leaves diſpoſed in a circular form. The cup conſiſts of one leaf, and is bifid; from this ariſes the piſtil, which afterwards becomes, together with the cup, a fruit or ſeed-veſſel of an oval form, and uſually containing very ſmall ſeeds: this ſeed-veſſel has two ſhelly ſubſtances at its top, the outer of which has been the bifid part of the cup; the inner is no other than the piſtil enlarged; theſe ſeparate tranſverſely when the ſeed is ripened, the lower part of the cup ſtill remaining fixed to the ſtalk.

The ſpecies of *purſelain*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved, or garden *purſelain*. 2. The narrow-leaved, or wild *purſelain*. 3. The broad-leaved garden *purſelain*, with gold yellow leaves. 4. The broad-leaved ſea-*purſelain*, with beautiful red flowers. 5. The red-flowered procumbent *purſelain* of Curaſſo, with long, thick, and ſhining leaves. 6. The procumbent *purſelain* of Curaſſo, with leaves like thoſe of the caper's buſh and red moſſy flowers. 7. The taller upright woolly *purſelain* of Curaſſo, with leaves like thoſe of kali, and pale red flowers. 8. The woolly procumbent *purſelain* of Curaſſo, with beautiful red flowers, and ſeed-veſſels ſomewhat pointed at the ends. 9. The woolly, procumbent, kali-leaved Curaſſo *purſelain*, with ſeed-veſſels hollowed at the ends.

The ſeveral ſpecies of *purſelain*, may be known when not in flower, by their having thick and fleſhy leaves placed alternately on their ſtalks. *Tourn.* Inſt. p. 236.

PORTUGALLICA *terra*, *earth of Portugal*, in the materia medica, the name of a fine aſtringent bole, dug in great plenty in the northern parts of Portugal, and eſteemed a remedy againſt poiſons and venomous bites, and good in malignant fevers. Whatever may be its virtues of this kind, however, it is manifeſtly an aſtringent of the very firſt claſs, and is uſed with great ſucceſs in fluxes of all kinds. It is well known in ſome parts of the world, beſide the kingdom where it is produced; but is not known in the Engliſh ſhops. The cheapneſs of our ſophiſticated bole armenic, having excluded this whole valuable claſs of medicines from our practice.

The characters by which the *Portugueſe earth* is known from the other red boles, are theſe: It is of a cloſe, compact, and regular texture, conſiderably heavy, and of a fine florid red, of a ſmooth and ſhining ſurface, eaſily breaking between the fingers and a little ſtaining the hands. It adheres firmly to the tongue, melts freely and readily in the mouth, and has a ſtrongly aſtringent taſte, but leaves a little grittyneſs between the teeth. It does not ferment with acids, and ſuffers ſcarce any change of colour in the fire. *Hill's* Hiſt. of Foſſ. p. 13.

PORTUMNALIA, among the Romans, a feſtival in honour of Portumnus, which was celebrated on the ſeventeenth of Auguſt. *Pitiſc.* in voc.

PORUS, (*Cycl.*) in natural hiſtory, a name given by authors to a peculiar kind of foſſile coral, of which there are many different ſpecies; theſe are all of a beautifully laminated ſtructure, and ſeem allied to the mycetitæ or fungitæ: they are ſeldom found looſe, but uſually bedded in hard marble, and with their pores filled up with ſparry or mineral matter. See Tab. of Foſſ. Claſs 7.

PORUS *cervinus*, in natural hiſtory, a name given by authors to a ſpecies of ſea-plant, found among the rocks in the coral fiſheries, and in other places. It grows at different depths, and ſeems to adhere to the rocks by a ſimple baſe, having no root, nor any thing in the place of one. It is branched in ſuch a manner, that with the help of a little imagination it has been forced into the reſemblance of a ſtag's horn. Its height is about an inch and half, often leſs when newly taken out of the ſea; it is of a fine ſnow white colour, but when it has lain ſome time to dry, it becomes of a duſky yellow. It is very thin, perfectly tranſparent, and ſeems compoſed of ſeveral fine membranes. When examined by the microſcope, an admirable ſtructure is diſcovered in it: the whole being compoſed of a membranous matter, in which are an infinite number of holes, and all theſe arranged into regular lines.

Count Marſigli has diſtinguiſhed this, which is the common kind of *porus cervinus*, or buckſhorn *porus*, by the name of *minor*, in order to prevent its being confounded with another leſs common kind, which Ferrante Imperato has deſcribed under the name of *porus cervinus*.

This larger kind is found alſo growing on the rocks in the coral fiſheries; but it always is found at great depths, never near the ſurface, as the other often is. It grows to the rock by a ſmall baſe, and from thence riſes to a ſhort trunk, which ſpreads itſelf out into ſeveral flat branches, divided every where into two, as thoſe of moſt of the ſea-fucuſes are; and theſe are ſo expanded as to form what people imagine, a reſemblance of a ſtag's horn. This grows to a little more than two inches in height, and is of a beautiful pale yellow, or ſtraw colour, even while growing, and looks gloſſy and ſhining, as if covered with a thin coat of varniſh. It is as thin as the fineſt paper; and when viewed by the microſcope, is found to be of a particular texture. It is ſometimes found growing to the ſhells of ſea-fiſhes; but of thoſe only which live in great depths of water. Count Marſigli has given elegant figures both of this and the ſmaller kind, not only in their natural ſtate, but as they appear to the microſcope. *Marſigli*, Hiſt. de la Mer.

POSCENIUM, or POSTSCENIUM, among the Romans, the back part of the theatre, where the actors retired to undreſs themſelves. *Danet.* in voc.

POSCENIUM was ſometimes uſed to ſignify a lady's dreſſing-room, where the paint and waſhes were kept and uſed, and where men were not allowed admittance. *Pitiſc.* in voc. See the article PARASCENIUM, *Cycl.*

POSIDIA, Ποσειδια, in antiquity, a feſtival in honour of Neptune, called Ποσειδων. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 426.

POSIDIUM, Ποσειδων, in chronology, the ſeventh month of the Athenian year. It conſiſted of thirty days, and anſwered to the latter part of our December and the beginning of January. See MONTH.

It had this name from the feſtival Poſidonia celebrated in it.

POSIDONIA, Ποσειδωνια, in antiquity, the ſame with *poſidia*. See POSIDIA.

POSIQUIT, in natural hiſtory, a name given by the people of the Philippine iſlands to a ſmall bird very common among them, and approaching to the nature of the canary bird, but ſmaller, and wanting its harmonious voice.

POSITI, among the Romans, an appellation given to the dead when placed at the door with their feet outwards, till the time of their interment. See BURIAL and BURYING. *Hofm.* Lex. in voc.

POSITION, *poſitio*, in muſic, is uſed for the putting down the hand in beating time. See THESIS.

POSITIONAL *libel.* See ARTICULATED *libel.*

POSSESSIO *fratris*, in law, is where a man hath a ſon and a daughter by one woman or *venter*, and a ſon by another *venter*, and dies, if the firſt ſon enters and dies without iſſue, the daughter ſhall have the land as heir to her brother, although the ſecond ſon by the ſecond *venter* is heir to the father: but if the eldeſt ſon dies without iſſue, not having made an actual entry and ſeiſin, the younger brother by the ſecond wife, as heir to the father, ſhall enjoy the eſtate, and not the ſiſter. 1 Inſt. 11, 15. Terms of Law.

POSSESSION (*Cycl.*)—POSSESSION, in mining, is the right to a meer of ground, which the miners enjoy, by having ſtones upon that ground; and it is taken generally for the ſtones themſelves; for it is the ſtones that give *poſſeſſion*. *Houghton's* Compl. Miner in the Explan. of the Terms.

POSSUM, a name by which many have called the *opoſſum*. See the article OPOSSUM.

POSTERIOR (*Cycl.*)—POSTERIOR *penis*, in anatomy, a name given by many authors to a muſcle more generally known at this time by the name of the *erector*. See ERECTOR.

POSTICUM, in architecture, the poſtern gate or back door of any fabric.

POSTOMIS, among the antients, a barnacle or iron inſtrument fixed on the noſe, or put into the mouth of a horſe to make him quiet. *Pitiſc.* in voc.

POSTURE (*Cycl.*)—POSTURES *of the body*. The continued unnatural *poſtures* of the body, are the occaſions of many very unhappy effects in the human frame; crookedneſs in ſhape, is very frequently the conſequence of them. See DISTORTION. And it is no uncommon thing to ſee ſchool-boys, who are forced to be continually bending to write upon their knee, or upon a low form, very terribly afflicted by means of the compreſſion which that unnatural and continued *poſture* has given the lower part of the breaſt and the viſcera contained in the epigaſtrium; and particularly thoſe unhappy youths, who, from being ſhort-ſighted, are expoſed to a greater degree of ſtooping than the reſt, have been found terribly afflicted with diſorders of the breaſt and of the lower belly.

On applying for relief in theſe complaints, the phyſician uſually forgets to enquire into the cauſe, and hearing nothing of the continued bending *poſture* of the body, which is the occaſion of all the diſorders, the medicines he gives prove ineffectual with ſome, and with others greatly heighten the diſorder. But when the preſcriber will be at the pains of informing himſelf of the cauſe in theſe caſes, and forbid the continuance of the *poſture* which has been the ſole occaſion of them; nature alone will often make the cure, or if not alone, yet very often with this caution the methods will prove ſucceſsful, which were ineffectual, or even hurtful without it.

Other ſchool-boys have been found ſubject to ſeveral diſorders of the head, the breaſt and eyes, and to many other complaints from which the uſual methods in the like caſes have been found wholly ineffectual to relieve them; or if they have been cured from time to time, they have been always found ſubject to relapſes: and in many of the ſchools of France, no remedy could be found for theſe complaints, till Mr. Winſlow found, on enquiry, that it was a common cuſtom among theſe youths to ſleep all night with their heads thrown back,

and lying over the bolster; and the giving orders, that they should be watched, and not suffered to sleep in that manner for the future, proved with most of them sufficient for the cure, without any further assistance, and that in many cases, even in maladies which had been of so long standing as to become in a manner habitual.

How frequently does it happen, that the not regarding things of this kind, which has been the cause of diseases, occasions the most unhappy events in the course of their cure? nay, sometimes irrecoverable misfortunes happen, without the physicians being able to guess why; and this sometimes after a seemingly perfect cure. A very remarkable instance of a thing of this kind Mr. Winslow gives, in the case of a woman to whom he was called to examine the cure of a fracture of the thigh. The person was lame after the cure, notwithstanding that there were all the common proofs of the fracture's having been perfectly well reduced, and that the bone had united in its proper shape and dimensions, and no way differed from that of the other thigh. He caused the person to be laid flat down, and when she was in that position, placing the knees, legs, and feet perfectly even, the thigh which had been set appeared perfectly like the other; but observing, that in a moment afterwards, the leg on the fractured side thrust itself up, as if of its own accord, out of the level of the other, and appearing then shorter than the other, he examined the hips; and perceiving that they were perfectly even while the leg was thus a little elevated, he again depressed it to the level of the other, and then the hips became uneven and oblique. It appeared very plain from this, that the thigh-bone had lost somewhat of its original length from the irregular coalescence of the fracture; and that the surgeon who had set it, for want of examining the attitude of the hips at the same time with that of the thighs, had deceived himself, by trusting the common method of examination, into a belief that the thigh was of the proper length: what adds greatly to the occasion of error in the common way of examining these reduced fractures, by comparing the length of the two legs is, that the patient, dreading pain, always gives into the deceit, and naturally depresses the hip, without considering why, till the leg, tho' really much shorter, appears of the same length with the other. Mem de l'Acad. Scienc. Par. 1740.

POT *(Cycl.)*—Pot, in our old writers, a head-piece of war. It is mentioned stat. 13 Car. II. c. 6. *Blount.*

Glass-Pots. See Glass-*pots.*

Pot-*ash* (*Cycl.*)—The art of reducing vegetables to this state is a very valuable one; the soap-maker, fuller, scowerer, dyer, and glass-man, as well as the chemist and apothecary, depending greatly on it in many particulars.

The authors who are farther to be consulted in this case, are Glauber, in his prosperity of Germany; but the chemical foundation of the whole appears in Boerhaave's chemistry, and the papers of Stahl on this subject.

This salt has been made in New England in considerable quantities from rotten wood. What gave the occasion of knowing it, was, that a white oak in that province decayed, and a third part of its substance became rotten. This rotten part was tried to burn, and was found to turn a'most wholly into a fine alkali salt, or pot-ash, much stronger than that which is made in the usual way. What was most observable in the making of this salt was, that while the wood was burning, it would melt of itself, and run down into hard lumps of salt; and this, none of the wood of the same tree, which was found, would do, but only the rotten part: and what was most rotten of all, yielded the greatest quantity of salt, and that the most readily; whereas all the common alkali salts of wood, made by incineration, are blackish at first; and a lixivium made of them, altho' often filtered, will still be of a brown colour, occasioned by some of the charcoal of the wood so closely united to the salt as not to be easily separated from it. This alkali made from rotten wood was very white, even before solution; and the lixivium made with it was not at all tinged with brown, but clear like pure water, only a very small quantity of ashes subsided to the bottom. The lixivium was easily decanted from this, without the trouble of filtration; and when evaporated to a driness, left the salt perfectly fine and pure. In the making this salt, as the fire grows more intense, the wood is seen to run together into great lumps, and bubble with a hissing noise.

The weight of the *pot-ash* prepared in the common way is very inconsiderable, in proportion to the wood used; but in this, the salt nearly equals the whole weight of the wood. In the common way of making the *pot-ash*, the salt is never distinguished by the eye among the ashes, nor even causes them to run into lumps; but in this case the salt always runs into large lumps, and is as easily distinguished from the rest of the ashes, tho' white, as salt of tartar of the purest kind would be.

It is very certain, that rotten wood in many places has been found, on trial, to yield much less salt than sound wood; but the sound wood of this tree being tried, was found to yield no more salt than other wood, and consequently much less than the rotten part of it. On examining this tree on the spot, it was thought by good judges, that it had been at some distance of time struck with lightening, it being evidently torn from the top to the bottom: on that side where the decayed part separated from the sound, there had been a channel of about five inches wide all the way down; but this was closed over by succeeding bark, and shewed no trace of the accident till on examining underneath, where the tree was found black for such a space, and the bark not of a piece with the rest.

From this it may be conjectured, that the wood having been for so long a time, as till the growth of this bark, exposed to the wind and weather, naturally became rotten from the wet it received; and that the lightening having penetrated the wood, had so altered and disposed the parts and pores of it, that they attracted and retained the nitrous salts of the air in great abundance, even as salt of tartar, and other the like salts, do; which, as Glauber observes, will be reduced, in continuance of time, to an absolutely nitrous salt, and the quantity also considerably increased.

The parts of this rotten wood were of a very different structure from those of ordinary wood in this condition; and tho' the lightening had not calcined it into a salt, yet it had, as appears, sufficiently altered it to give that tendency to imbibe, and a power to retain the nitrous particles from the air, as well as the alkalies of vegetables perfectly calcined will do. If it should be objected, that nitre alone will not calcine into an alkali, it is easily answered, that nitre with charcoal will; and the remaining wood might very well serve as charcoal in this process. Phil. Transf. N°. 360 p. 121.

Some sort of *pot ashes* have been found to contain a large quantity of sea-salt, which is probably mixed with them by the makers; not only as it is much cheaper, but as it makes them whiter, and more easily run into large masses. Med. Ess. Edinb. abr Vol. I. p. 165. Not.

The French have two kinds of *pot-ash*, the produce of their own manufactures; the method of making which M. du Fay, of the academy at Paris, describes in the following manner.

The first which is the common or coarser kind, is made of the beech or elm; the first of which trees they always find to yield the largest quantity.

They cut down the largest and most full grown trees, and cutting them into pieces of ten or twelve foot long, they lay them together in form of a pile, and burn them to ashes in the open air. They gather up the ashes, and make a very strong lixivium of them in water; into this liquor they throw pieces of old rotten and spungy wood, which is, from its texture, capable of imbibing a great quantity of humidity: they use so many of these pieces as are sufficient to soak up the whole quantity of their lixivium. When this is done, they dig a square pit in the earth; over this they lay some iron bars, to sustain a quantity of dry wood, to serve as fuel. When they have laid together a sufficient quantity of this, they pile upon it the rotten billets which have imbibed the lixivium; and when the dry wood underneath is set on fire, and heats the top of the pile, the lixivium loses its water by the heat, and the salt contained in it is seen running down through the fire, in form of a shower: this is received in the pit made on purpose for it. When all is melted out of the billets at first laid on, they bring others, which the fire acts upon in the same manner; and so on, till the whole pit is filled with *pot-ash*.

When this is done, they remove the fire as quickly as they can; and with rakes clear the surface of the *pot ash* as well as they can from pieces of charcoal and ashes which have fallen into it: but with all their care, they are not able to prevent a great deal, both of coals and ashes, remaining in it; as is easy to conceive from the manner of the process. The salt after this forms one solid cake or mass, and this they dig up out of the pit while it is yet hot; and barrel it up for fear of its receiving damage from the humidity of the air, which it is very ready to imbibe. This is the French *pot-ash* of the common or coarse kind.

The finer or purer kind is made of the same wood with the other, and the process is conducted in the same manner, so far as to the making of the lixivium; but, when this is prepared, instead of soaking it up with rotten wood, they pour it off into an iron caldron of a large size, and evaporate it, still adding more lixivium as the former boils away, till they have employed all they have made; they then continue the fire till the whole humidity is evaporated: they then take the dry mass of salt out of the bottom of the vessel, and put it into a furnace made with a close arched top; by means of which the flame is reverberated from all parts upon the salt. They here give it so much fire as serves to calcine it to a whiteness, and then the whole operation is finished.

It is seldom, however, quite white; but usually retains somewhat of the colour it had before its calcination. This the workmen say is owing to the nature of the wood the ashes were made from. They say that those trees which grow on the tops of high hills, yield a *pot-ash* of a pale blue colour; and those which grow in wet marshy places, yield a reddish salt. Trees which have stood in other soils and situations, they say, yield a white *pot-ash*; but they observe, that none yield it in so large a quantity as those which grow on the tops of mountains. Mem. Acad. Par. 1727.

POTAMOGEITON, *pondweed*, in the Linnæan system of botany, a genus of plants, the characters of which are these: the

the flower has no calyx or cup; but is compofed of four obtufe, roundifh, hollow, and open petals, which fall off before the ripening of the feeds. The ftamina are four plane, obtufe, and very fhort filaments; the antheræ are double and fhort; the piftillum has four germina, which are all oval and pointed: thefe have no ftyle, but obtufe ftigmata. There is no other fruit than four feeds fucceeding each flower; thefe are of a roundifh, but flatted figure, gibbofe, and pointed. *Linnæi* Gen. Plant. p. 55.

The characters of this genus, according to Tournefort, are thefe: the flower confifts of four leaves, difpofed in form of a crofs, and having no cup; the piftil becomes at length a congeries of four feeds, of an oblong figure, collected into a fort of head.

The fpecies of *potamogeiton*, enumerated by Mr. Tournefort, are thefe: 1. The roundifh-leaved *potamogeiton*. 2. The long-leaved ferrated *potamogeiton*. 3. The plantain-leaved alpine-*potamogeiton*. 4. The broad fhining-leaved *potamogeiton*. 5. The curled-leaved *potamogeiton*, called *frog's lettuce*. 6. The narrow undulated-leaved *potamogeiton*. 7. The leffer *potamogeiton*, with denfe fharp-pointed, and not ferrated leaves. 8. The narrow-leaved branched *potamogeiton*. 9. The graffy-leaved *potamogeiton*, with flatted ftalks. 10. The fmall graffy-leaved *potamogeiton*, with round ftalks. 11. The *potamogeiton* with flowers at the knots of the ftalks, called *water-milfoil*. 12. The pennated-leaved *water-milfoil*, called by fome *feathered water-milfoil*. *Tourn.* Inft. p. 233.

POTAMOPITYS, in botany, a name given by Buxbaum to a new genus of plants, fomewhat refembling the limnopeuce in its general external appearance; but greatly differing from that plant in its flower and fruit.

The ftalk is about four inches high, and is made up of feveral joints, fixed in the manner of fo many cups one into another. The leaves ftand in form of a ftar, eight, or thereabout, at every joint: thefe are narrow at the lower part of the plant; but toward the top, they are broader, and ftand fewer at a joint, fometimes only two. The flowers grow out of the alæ of the leaves, and are white and compofed of four petals, difpofed in form of a crofs: they ftand in a four-leaved cup, and have no pedicle. The piftil occupies the center of the flower, and is furrounded by four ftamina. The feed veffel is round, divided into four cells, and filled with flender and lunated feeds. It flowers in May, and is common in the marfhy grounds in Thrace, near the Bofphorus. Act. Petrop. Vol. 1. p. 243.

POTATOE. The moft advantageous way of propagating *potatoes* is, the planting them at large diftances, and digging or horfehoeing the ground feveral times between them.

Mr. Tull gives an example of this, in which the hoeing fucceeded much better than dung, and without the expence of it. A piece of ground was planted with *potatoes*, the greater part of it in the common way; but in one part, worfe than the reft, they had been fet at a yard diftance every way. The reft of the ground was dunged; this poor part had no dung, but was ploughed deep at feveral times four different ways, fo that the ground was ftirred and broken thoroughly every where about the *potatoes*. The confequence was, that tho' no dung was ufed here, and tho' the plants appeared much weaker than in the dung part, yet the crop was greatly better than that of the other part of the field. The roots here were all large, and in the other parts of the field, where the dung had been ufed without ploughing, they were fo fmall, that the crop was fcarce worth taking up.

This is one of many inftances of the no great ufe of dunging land, without properly ftirring it up; and ferves to prove, what the crops of corn and every thing elfe confirm upon trial, that the ftirring the earth fufficiently, without any farther trouble, will anfwer better without any other manure, than all the manure in the world without it. *Tull's* Horfehoeing Hufbandry.

POTENTILLA, in botany, a name given by many authors to the argentina, or filver weed; and by fome with the addition of the epithet major, or the greater *potentilla*, to the ulmeria, or meadow-fweet. *Ger.* Emac. Ind. 2.

POTERIUM, a word ufed by many for the prickly pimpernell. See PIMPINELLA.

POTHOS, in botany, a name ufed by Theophraftus, and fome other of the old writers, for the aquilegia or columbine. *Ger.* Emac. Ind. 2.

POTINCOBA, in botany, a name by which fome authors call water-pepper, or the fharp arfmart. *Pifo*, 221.

POTIRONE, in botany, a name given by the people of Burgundy to a ftinking kind of fungus, found about the roots of trees. They have alfo extended the name much farther, and ufe it for a fort of touchwood, or rotten wood of the oak, and other trees common in the forefts of thofe countries, which fhines in the night, and has the fame fmell with that fungus.

POTRIMPOS, the name of an antient Pruffian idol, worfhiped under oaks, and to which human facrifices of enemies were offered. Mem. de l'Acad. de Berlin, Tom. 2. p. 358. Peicunos and Picolos were idols of the fame kind.

POTTERN-*ore*, a kind of lead ore. See LEAD-*ore*.

POUCH, in the military art. A grenadier's *pouch* is a fquare cafe or bag of leather, with a flap over it, hanging in a ftrap of about two inches broad over the left fhoulder, in which he carries his granadoes.

POUDRE *des Chartreux*. See KERMES *mineral*.

POUNCE (*Cycl.*)—POUNCE, among writing-mafters, a powder made of gum-fandarac, which being rubbed on the paper, makes it lefs apt to imbibe the ink: it is therefore ufed in this manner by thofe who are curious in the art of the pen, by which means the writing appears more precife, fharp, and determinate.

The varnifh-makers alfo ufe to diffolve it in oil of turpentine, or in linfeed oil, or in fpirit of wine; from which mixture is produced a kind of liquid varnifh.

POUND (*Cycl.*)—In Scotland the *pound* is divided into two marks, or fixteen ounces, the ounce into fixteen drops, and a drop into thirty-fix grains. Tr. Pract. Geom. p. 153.

POUND *averdupois*. The Englifh *averdupois pound*, taken from the reputed ftandard, is about 7000 Troy grains, and the ounce about 437 and an half fuch grains. But it is to be obferved, that the ftandards kept at the Exchequer differ a little from each other.

The Scotch, Paris, or Amfterdam *pound*, is to the *pound averdupois* as thirty-eight is to thirty-five. Tr.Pract.Geom.p.153.

POUND *breach*, in law. If a diftrefs be taken, and impounded, though without juft caufe, the owner cannot *break* the *pound*, and take away the diftrefs; if he doth, the party diftraining may have his action, and retake the diftrefs wherever he finds it: and for *pound breaches*, &c. action of the cafe lies, whereon treble damages may be recovered. 1 Inft. 161. 2 W. & M. c. 5.

Alfo it is faid, that all *pound breaches* may be enquired of in the fheriff's turn, as they are common grievances, in contempt of the authority of the law. 2 Hawk. P. C. 67. *Blount.*

POUND *land*, of old extent. This is alfo called *librata terræ*, and is ufed in Scotland to denote a certain portion of arable land, containing four oxengate, or fifty-two acres. Tr. Pract. Geom. p. 87. See Ox-*gang*.

POUND *Troy*, in Scotland, which by ftatute is to be the fame as the French *pound*, is commonly fuppofed equal to fifteen ounces and three quarters Troy Englifh weight, or 7560 grains. But by a mean of the ftandards kept by the dean of gild of Edinburgh, it weighs $7599\frac{1}{16}$, or 7600 grains.

POUR *fair proclaimer, que null injett fines ou ordures en foffes ou rivers pres cities*, &c. in law, an antient writ, directed to the mayor or bailiff of a city or town, requiring them to make proclamation, that none caft filth into the ditches or places near fuch city or town, to the nufance thereof; and if any be caft there already, to remove the fame. It is founded on the ftatute 12 Rich. II. c. 13. F. N. B. 176. *Blount, Cowel.*

POUR *feifer terres la femme que tient en dower*, in law, an antient writ, whereby the king feized the land which the wife of his tenant *in capite* had for her dowry, after his difeafe, if fhe married without the king's leave; by virtue of the ftatute of the king's prerogative c. 3. F. N. B. 174. *Blount. Cowel.*

POUSSE-*pied*, in natural hiftory, the French name for a genus of fhell-fifh, called by writers of other nations the *policipes*. See POLICIPES.

Rondeletius has very improperly confounded this genus of fhells with the balani marini; but the two genera are extremely different, as well in their general figure as in this, that the *pouffe-pied* always has a pedicle to which it is affixed, and the balanus never has any. Every *pouffe-pied* is compofed of feveral pointed fhells or valves; the bafes of the larger of thefe are affixed to the pedicles. The outer furface of the fhell is of a moufe colour, and is rough like chagrin; but the infide is filled with a white flefh, which, when boiled, becomes very red, and is of a fine tafte and good nourifhment, being in nothing inferior to the flefh of cray-fifhes.

The *pouffepied* differs from the concha anatifera in this, that the anatifera is only compofed of five pieces; and the pedicle is longer and flenderer, and rarely adheres to that of any other fhell of the fame kind; and the fhell is only filled with a mucous fluid, and a few plumofe fubftances. On the contrary, the *pouffepied* is never found fingle; it is always feen in clufters, the pedicles joining and adhering to rocks under water, fo that it is bare only at the time of the tide being out. The union of the bafes of the pedicles of thefe fhells forms a fort of tree, of which the loofe part of each pedicle makes a fort of branch; and the tops of thefe are furnifhed with feveral triangular pieces, each of which has its plume belonging to it. This pedicle is fhorter and thicker than that of the concha anatifera, and is eatable; and, indeed, is the only part of the animal that is fo. The fifh contained in the fhell, is nearly the fame with the fifh in the concha anatifera, excepting the difference in the length and thicknefs of the arms, or branches of feathers. Hift. Nat. Eclairc. p. 359.

POUST, an Indian name for a very poor and coarfe kind of opium, made by boiling the ftalks and leaves of the opium poppy in water, and then evaporating the clear liquor to the confiftence of a folid extract.

POUTING, or *whiting*-POUT, in ichthyology, a name given to a fpecies of bearded gadus. See GADUS.

POWCHES, in a ſhip. The ſeamen call by this name the ſmall bulk-heads made in the hold, to ſtow corn, goods, or the like, that it may not ſhoot from one ſide to the other.

POWDER *(Cycl.)*—*Gun*-Powder. See Gun.

Powder-*flasks*, in artillery, are moſt commonly made of horn, of any convenient ſize and figure, to carry *powder* for priming of cannon: this is their chief uſe in armies.

Sometimes they are ſo made as to have a meaſure for the charge of the piece at top, but this is of more uſe to gentle men in fowling, &c. than to ſoldiers, who have the charges of their piece put into cartridges, which they bite off, and firſt prime, and then load.

Powder-*room*, in a ſhip, that part of the hold wherein the *powder* is ſtowed.

POWER *(Cycl.)*—If any *power* of a quantity be divided by a greater *power* of the ſame quantity, the quotient muſt be ne gative. For the rule for dividing any *power* of a quantity by another *power* of the ſame, is to ſubtract the exponent of the diviſor from the exponent of the dividend, and make the difference the exponent of the quotient.

For inſtance, $\frac{a^6}{a^4} = a^{6-4} = a^2$ and $\frac{a^m}{a^p} = a^{m-p}$. Hence if p be greater than m, the exponent $m-p$ muſt be negative. Thus if $p=m+n$, then $\frac{a^m}{a^p} = \frac{a^m}{a^{m+n}} = a^{-n}$.

It is obvious that $\frac{a}{a} = a^{1-1} = a^0$. But $\frac{a}{a} = 1$; and therefore $a^0 = 1$. In like manner $\frac{1}{a} = \frac{a^0}{a^1} = a^{-1}$; $\frac{1}{aa} = \frac{a^0}{a^2} = a^{0-2} = a^{-2}$; $\frac{1}{aaa} = a^{0-3} = a^{-3}$, ſo that the quantities a, 1, $\frac{1}{a}$, $\frac{1}{a^2}$, $\frac{1}{a^3}$, $\frac{1}{a^4}$, &c. may be expreſſed thus, a^1, a^0, a^{-1}, a^{-2}, a^{-3}, a^{-4}, &c.

This change of expreſſion is often of great uſe in the computation of fluxions and infinite ſeries.

When the quantity to be raiſed to any *power* is poſitive, all its *powers* muſt be poſitive. And when the radical quantity is negative, yet all its *powers*, whoſe exponents are even numbers, muſt be poſitive. For — × — gives +.

The *power* then can only be negative, when the exponent is an odd number. Thus the *powers* of $-a$ are $-a$, $+a^2$, $-a^3$, $+a^4$, $-a^5$, &c. Thoſe whoſe exponents are 2, 4, 6, &c. are poſitive, but thoſe whoſe exponents are 1, 3, 5, 7, &c. are negative. *Mac. Laur.* Algebr. p. 37, 38.

Hence if a *power* have a negative ſign, no root of it denominated by an even number, can be aſſigned; ſince no quantity multiplied into itſelf an even number of times can give a negative product. Thus the ſquare root of $-aa$ or $\sqrt{-aa}$ cannot be aſſigned, and is what mathematicians call an *impoſſible*, or *imaginary* quantity or *root*. See Root.

Obſerve, that every *power* has as many roots, real and imaginary, as there are units in the exponent of the *power*. This holds true of unity itſelf. *Mac. Laur.* Algebr. p. 128. See the article Unity.

Imperfect Power, in algebra, is uſed for a *power* that has a fractional exponent; thus $a^{\frac{1}{2}}\, a^{\frac{2}{3}}\, a^{\frac{3}{5}}\, a^{\frac{7}{8}}$, &c. are imperfect *powers*. *Mac. Laur.* Algebr. p. 44.

Theſe are otherwiſe expreſſed by placing the given *power* within the radical ſign $\sqrt{}$, and placing above the radical ſign the number that denominates what kind of root is required. Thus,

$$a^{\frac{3}{2}} = \sqrt[2]{a^3};\quad a^{\frac{5}{3}} = \sqrt[3]{a^5};\quad a^{\frac{m}{n}} = \sqrt[n]{a^m}.$$

Theſe imperfect *powers* are alſo called *ſurds*. See Surd, *Cycl.*

Negative Power, in algebra. See Negative *power*.

POWTER, *or Engliſh* Powter, the name of a peculiar ſpecies of pidgeon, called by Moore the *columba gutturoſa Anglica*.

It was firſt bred in England, and is of a mixed breed, between what is called the horſeman and the cropper. It is a very beautiful ſpecies, and is valued for its length of legs and body, neatneſs of crop, and ſlenderneſs in girth, added to the beauty of its feathers. This ſpecies is often eighteen, ſometimes twenty inches long from the end of the bill to the extremity of the tail. Its legs, from the upper joint of the thigh to the toe-nail, is ſometimes ſeven inches; the crop is large and round, eſpecially toward the beak, filling alſo behind, and making almoſt a perfectly orbicular figure. They are either blue-pied, black-pied, red-pied, or yellow-pied; the laſt colour is moſt valued. *Moor's* Columbarium, p. 35.

Pariſian Powter, a ſpecies of pidgeon called by Moore *columba gutturoſa Pariſiorum*.

It was firſt bred at Paris, and thence ſent to Bruſſels, whence it was afterwards brought into England. It reſembles the Engliſh *powter*, but is ſhort-bodied, ſhort-legg'd, thick in the girth, and long-cropp'd. It is admired for the beauty of its feathers, which is peculiar to itſelf; it reſembling in this a fine piece of that ſort of needle-work which the ladies call the Iriſh ſtitch, being chequered with various colours in every feather, except the flight, which is white. It has generally a good deal of red intermixed with the other colours, and the more it has of this the more it is eſteemed.

Horſeman POWTING, a name given to a mixed breed of pidgeons, produced between thoſe two kinds known by the names of the *cropper* and the *horſeman*, according to the number of times that the young are bred over from the *cropper*. They are diſtinguiſhed by the names of the firſt, ſecond, or third breed.

Theſe are a very agile and nimble pidgeon; and by their continually flying up and down about the dove-houſe, are apt to bring in other ſtray pidgeons, which cannot find their houſes. They are obſerved to breed often, and take great care of their young ones. *Moore's* Columbarium, p. 38.

POX *(Cycl.)*—*Small* Pox. Dr. Hahn endeavours to prove, that the *ſmall pox* was deſcribed by the old Greek phyſicians under the name of carbuncle.

Dr. Hahn's treatiſe on the antiquity of the *ſmall pox*, has been criticized by Dr. Werlhoff, who endeavours to ſhew, that Dr. Hahn's quotations from the old Greek writers concerning the carbuncle, cannot be underſtood of the *ſmall pox*, which is a diſeaſe we have no account of till the Saracens diſperſed it. Med. Eſſ. Edinb.

Dr. Hilſcher recommends cutting off the hair in the *ſmall-pox*, by which perſpiration may be increaſed. This method was practiſed on the king of Spain's ſon Don Carlos, and on a Saxon prince with ſucceſs. Med Eſſ.

Dr. Martin of Lauſaunne, recommends bathing the face and body with cloths dipped in tepid water every four hours during the eruption of the *ſmall pox*; aſſuring that it has excellent good effects. Hiſt. de l'Acad. des Sciences, 1737.

Dr. Haller tells us, that camphor aſſiſts greatly to fill the puſtules of the *ſmall pox* of the confluent kind with petechiæ. Commerc. Norimb. 1736. Hebd. 10. § 1.

Dr. Lobb diſapproves entirely of blood-letting in the *ſmall pox*, and thinks the diſeaſe may be prevented, or cured, without any eruption, and that a ſpecific may be found: he propoſes the Æthiops mineral as ſuch, and relates ſome examples of the diſeaſe being, in his judgment, prevented by the timely uſe of it. The biſhop of Cloyne ſeems to aſcribe the ſame virtues to tar-water. See Tar-*water*.

Dr. Wintringham ſays, he never obſerved antiphlogiſtic medicines, which open the belly, diluting clyſters or ſuch like, to have any bad effects in this diſtemper; but on the contrary, has always ſeen them ſerviceable to young, vigorous, plethoric patients; while too bound a belly frequently at laſt produces a dangerous diarrhœa. He propoſes in urgent caſes of the confluent *ſmall pox*, where from the reſorption of the variolous matter there is great danger of increaſing the ſecondary fever, that the puſtules ſhould all be opened, and treated as ſo many ulcers. See his Commentar. Noſologicum.

Bloody urine is looked upon as a forerunner of death in the *ſmall pox*; but we have inſtances of perſons recovering under ſuch ſymptoms. See Phil. Tranſ. N° 470. Sect. 11.

Great Pox. For the cure of the *lues venerea*, Dr De Sault, in his treatiſe on this diſeaſe, recommends frequent frictions with large quantities of mercurial ointment made with one third of quickſilver; to wit, from two or three drams to an ounce, or an ounce and an half every night, or every other night, taking care to keep the belly in a purging way, by clyſters, laxatives, or the ſtronger purgatives, if the mercury begins to affect the mouth. He ſays this method is ſure, and altogether ſafe, and he relates ſeveral hiſtories of cures performed by it, not only in the *lues venerea*, but in many other diſeaſes, particularly in obſtructed hardned glands, the liver, teſtes, &c. Med. Eſſ. Edinb.

Mr. Douglas greatly commends De Sault's method, and it is ſaid that it has been practiſed with ſucceſs in ſome of the hoſpitals in London. See A Letter on the cure of the venereal diſeaſe.

Dr. Werlhoff prefers frequently repeated ſmall doſes of mercury to a ſalivation, for the cure of the *lues venerea*. Commerc. Norimb. 1235. Hebd. 13. § 4

Mr. Macky, profeſſor of hiſtory in the univerſity of Edinburgh, ſent the Royal Society a voucher for the grandgor *(lues venerea)* raging at Edinburgh in 1497. It is a royal proclamation, ordering all who had the diſeaſe, or who had attended people under it, to repair forthwith to an iſland in the Frith of Forth. Phil. Tranſ. N° 469. § 5.

PRACTORES, Πράκτορες, among the Athenians, officers appointed to receive the money due to the city from fines laid upon criminals. *Potter*, T. 1. p. 81.

PRÆBIUM, a name uſed by medical authors to expreſs a doſe of any thing, or the quantity of a medicine to be exhibited at one time.

PRÆCIÆ, among the Romans, the ſame with *præclamitatores*; which ſee.

PRÆCIPE *(Cycl.)*—Precipe *in capite*, a writ iſſuing out of the chancery, for a tenant holding of the king *in capite*; *viz.* in chief, as of his crown. Magn. Chart. c. 24. Reg. Orig. 4. *Terms of law.*

PRÆCLAMITATORES, among the Romans, officers that went along the ſtreets of Rome before the *flamen dialis*, to oblige all people to give over their work on public holydays;

for if the *flamen* saw any one at work, the service of the gods could not be performed. *Danet.* in voc.

PRÆCLAVIUM, among the Romans, was used to signify the *prætexta*. See PRÆTEXTA, *Cycl.*

PRÆCO, among the Romans, the public crier, an officer whose business it was in the assemblies of the people to call the classes and centuries according to their order, and to order silence to be kept in the temples during the time of sacrificing.

The assistance of the *præco* or public crier, was used on many other occasions, as at public sales or auctions, funerals, games, in courts of justice, to publish things lost, &c. *Pitisc.* Lex. Ant in voc. See CERYX.

PRÆCOCIA *mala, apricocks.* The method of cultivating and propagating the several sorts of this fruit, is this: They are all to be propagated by grafting them on plumb-stocks, and will readily take with almost any species of plumb, provided that the stock be in a thriving condition. See GRAFTING.

The Breda and Brussels *apricocks*, are best to be made standard trees, all the rest are to be propagated against walls, and should have an east or west aspect. The borders under these walls should be four feet wide at least, and should be two feet deep in earth. If the place where they are planted be a loamy soil, the beds are to be raised pretty high above the level of the ground, and if chalk or gravel, it must be removed to a considerable width, to make room for fresh soil to be put in, but it need not be dug more than two feet deep. The best soil for them is fresh earth from a pasture ground, taken to ten inches deep, and laid with the turf among it to rot together, for a twelvemonth before it is used.

Such trees should be chosen for planting as are but of one year's growth from the budding, and where the soil is dry or moderately so, October is the best season for planting. For the manner of planting, see the article APPLE-*tree*.

No part of the head should be cut off at this time, unless there are some foreright shoots which will not come near the wall. In a good strong soil, or against a low wall, these trees should be planted at eighteen feet asunder; the stem is to be placed four inches from the wall, and the head inclined toward the wall, the branches should be then nailed up to the wall, and the surface over the earth must be covered with rotten dung, to keep out the frosts. In February the dung is to be removed, and the tree being held very steady the top is to be cut off to about three eyes above the bud, leaving the sloping side toward the wall. If the weather proves dry after this, they must be gently watered, and some turf or mulch laid round the root to keep off the sun's heat; and what branches are produced must be nailed up, except such as are produced foreright, which must be cut off.

At Michaelmas, when the trees have done growing, the branches must be again unnailed and cut off to a proper length, the stronger shoots being left of nine or ten inches long, the weaker five or six inches. After they are thus shortened, they must be again nailed up, and that as much in an horizontal direction as possible. The second and third summer the same rules must be observed, all the foreright shoots must be displaced as they are produced, nailing in the others horizontally to the wall; so that the middle of the tree may be kept open; and never shorten any of the shoots in summer, unless to furnish branches to some vacant spaces on the wall; and this should never be done later than April. The *apricock* produces its blossom buds not only on the last year's wood, but also on the cursons or spurs from the two year old wood; great care must therefore be taken not to injure or displace these.

The Brussels and Breda *apricocks* being planted for standards, require very little management, only in autumn or spring cut away all the dead wood, and such branches as cross one another. The Brussels *apricock* is the finest of all the kinds: it is ripe in the middle of August. *Miller's* Gardner's Dict.

PRÆCONISSUS, in natural history, the name given by Ludovicus Dulcis, and other writers of his time, to a gem famous for its imaginary virtues: it is described to have been of the nature of the sapphire, but somewhat approaching to the colour of the chalcedony: this seems to make it the leucosapphirus of other authors.

PRÆFECTURÆ, among the Romans, towns in Italy, which were neither municipal, nor had the privilege of choosing magistrates of their own, like the colonies; but were governed by a magistrate sent from Rome, who was called *præfectus*, and his government a *præfectura*. *Pitisc.* in voc.

PRÆFERICULUM, among the Romans, a vase with a large prominent mouth used in the sacrifices of Ops. *Pitisc.* in voc.

PRÆFICÆ, among the Romans, were mourning women hired to attend funeral solemnities; where they praised the deceased, made a lamentation, beat their breasts, and distorted their faces, to excite others to mourn. *Danet.* and *Pitisc.* in voc.

PRÆFINE, in law, that fine which upon suing out the writ of covenant on levying *fines of lands*, is paid before the time is passed. 22 and 23 Car 2. *Blount.*

PRÆFURNIUM, a word used by chemical writers to express the anterior part of a furnace, by which the coals, or fuel are put in, and the ashes taken out.

PRÆMORSUM *folium*, among botanists. See LEAF.

PRÆNOTION is used by Lord Bacon for breaking of an endless search, which he observes to be one of the principal parts of the art of memory. For when one endeavours to call any thing to mind, without some *previous notion* or perception of what is sought for, the mind exerts itself and strives in an endless manner: but if it hath any short notion before hand, the infinity of the search is presently cut off, and the mind hunts nearer home, as in an inclosure. Thus verse is easier remembered than prose; because if we stick at any word in a verse, we have a *previous notion* that it is such a word as must stand in a verse. Hence also, order is a manifest help to memory; for here is a *previous notion* that the thing sought for must be agreeable to order. *Bacon's* Works, abrid. Vol. I. p. 136. and Vol. II. p. 474. See PRÆNOTION, *Cycl.*

PRÆPOSITUS *sacri cubiculi*, among the Romans, an officer who was to take care of the emperor's bed-chamber. His office was the same with that of our lord chamberlain, and he had the privilege of marching next to the captain of the horse-guards. *Danet.* in voc.

PRÆSALTOR, among the Romans, an appellation given to the chief director of the *salii*. *Pitisc.* in voc. See SALII.

PRÆSEPIA, a word used by authors to express the sockets of the teeth.

PRÆSICIA, in antiquity, those parts of the intrails of sacrifices which were cut off, and offered to the gods. *Hofm.* Lex. Univ. in voc.

PRÆSUL, among the Romans, the name of the chief of the *salii* or priests of Mars. He was so called *a præsiliendo*; *i. e.* dancing at the head of the *salii*. *Hofm.* Lex. Univ. in voc. See SALII, *Cycl.*

PRAMNION, in natural history, the name of one of the semipellucid gems, so distinct from all the others as to make properly a peculiar genus of fossils. It is called by many of the antients *morio* or *morion*, and by our lapidaries the *black agate*.

It is a stone of a very great concealed beauty. Our lapidaries, who know it by the name of the *black agate*, are very indeterminate in the application of that name, calling by it not only this, but every black stone capable of a good polish by the same name, and never looking for its great character, its hidden colour. It is found in the shape of our common flints and pebbles, but seldom larger than an egg; it appears on a slight inspection, to be of a fine deep black, but held up against the sun, or the light of a candle, it discovers itself to be of a fine strong red, without the least admixture of any other colour. It is most frequently of a purplish tinge, like the amethyst, but is at times found of all the degrees of red, from the pale flower colour of the hyacinth to the deep red of the carbuncle. It is of great hardness, and capable of an elegant polish.

It is produced only in the East Indies; and we sometimes have it thence among other stones, but it is not much regarded with us. The Romans were fond of it for engraving on, as we find by Pliny, and by a much more undeniable proof, many of the valuable antiques being cut on it. *Hill's* Hist. of Foss. p. 471.

PRAMNOS, a name given by the antients to a sort of austere wine which looked of a black colour till held up against the light, and then appeared of a deep purple: it is recommended by Hippocrates in hæmorrhages.

PRASINUM *viride*, a word used by the antients for verdigrease.

PRASION. The antient Greek writers have expressed three very different plants by this name.

The most common signification of the word is the common *marrubium* or horehound. It is in many places used also to signify the leek, and often for that sort of marjoram which we call *origanum onitis*, or pot-marjoram. Pliny describes this plant, and says that it was called *onitis* and *prasius*, and had the appearance of hyssop. This is but a bad description of the plant, and much inferior to the Greek epithet, which calls it the *capitated*, or *corymbous prasium*, for it bears its flowers in a sort of heads or corymbi.

Hesychius tells us, that the sea-weeds of the fucus and alga kinds, the sea-oaks, and sea-wracks, are called by some of the Greek writers *prasia*; and Theophrastus in one part of his works seems to have given this name to those plants.

The antients having used the word *prasion* in this sense, explains a passage in Galen which cannot otherwise be well understood, that is, where he calls the *empetrum marinum*, *prasioides*, like the *prasion*.

Dioscorides had called it *fucoides*, like the sea-fucus, and he was very well understood; but Galen coming after him, and expressing his sense by the word *prasioides*, which was supposed to signify resembling leeks, or horehound, or origanum, his readers were perplexed to find out what alliance the epithet he had chosen to use could have, either to the plant, or to the epithet of Dioscorides; but when it is found that *prasion* signifies the same as *fucus*, the whole is very intelligible.

PRASIS, a word used by some authors to express what they call green chalk, an earth used by the painters, and known among us by the name of *terre verte*.

PRASIUM, in botany, the name of a genus of plants, the characters of which are these: the perianthium consists of one leaf, and is of a turbinated bell-like shape, and divided at the end into two lips; these stand erect, and are permanent; the

upper one is broad, and divided into three acute segments; the under one is somewhat smaller, and is divided only into two. The flower is composed of one petal, and is of the labiated kind. The upper lip is erect and hollow, of an oval figure and emarginated; the under lip is broad and reflex, and is divided into three segments, of which the middle one is the largest. The stamina are four subulated filaments pressed closely under the upper lips of the flower; they stand expanded, one pair of them are shorter than the other, and the longest do not reach to the verge of the flower. The antheræ are oblong and lateral. The germen of the pistil is square. The style is slender, and is of the length and situation of the stamina. The stigma is acute and bifid, one of the segments being shorter than the other. The fruit consists of four roundish berries, which lie in the bottom of the cup, and each contain one seed. *Linnæi* Genera Plant. p. 280.

PRASIUS, in natural history, the name of a gem much approaching to the nature of the emerald, but of a coarser green, and wanting its hardness, and having in its green a cast of yellow.

It is the stone which the antients called *prasites*; and when of a greater than ordinary admixture of yellow, the *chrysoprasus*, and of which the gem distinguished by later authors under the name of the *smaragdoprasus*, is only one of the varieties.

The *prasius*, even in its most perfect state, is much less beautiful than most of the other gems: it is found of various sizes, and not unfrequently considerably large: it is seldom met with smaller than a pea; from that to the size of a horse bean is its most usual standard, from this to the size of a nutmeg it is more rarely found; and the larger specimens are coarser and less frequent than these.

It is of various figures, but is never found in a columnar or crystal-like form; this is declaring against the sense of our dealers in gems, indeed, who frequently buy and sell columns of the shape of sprig crystal, under the name of the *smaragdoprasus*; but these are all truly no other than crystals tinged to a coarse and dead green, and without any mixture of yellow; so that they are more properly *pseudosmaragdi*, or bastard-emeralds, than any thing of the *prasius* kind.

The *prasius* is frequently of an orbicular form, flatted on one side and convex on the other, and often oblong or oval; but more usually it is of a perfectly irregular shape, made up of a number of flat faces, as we often see some of the coarser nodules of the debased crystals from the German mines; and it is usually of an obscure or much less polished surface than many other of the native gems. Its colour is a dusky green, with a mixture of yellow, and often of bluish; and its most valuable pieces are of the hardness of the garnet; and its worst, which are truly *prasii*, are considerably harder than crystal; the columnar *prasii*, as they are called, are, on the contrary, often as soft, or softer than pure crystal. It is like the other gems, found in the different specimens of all degrees of colour, from its usual dusky green to the mere colour of water; it is at times found also with more or less yellowness in the different specimens, or in the different parts of the same specimen, and has sometimes a milky cast among the green: authors have distinguished it according to these its different appearances, by four names.

1. The *prasius* or *prasites*, simply so called. This is the name given to the gem in its most perfect state, in which it has a considerable share of yellow with the green, and the green is of a more pure and grassy colour.

2. The *smaragdoprasus*. This is the name given it when there is less yellow in the colour and some mixture of blue with the green.

3. The *chrysoberyllus*. This is the name given to the *prasius* when it has the same bluish cast, with a greater admixture of yellow.

4. The *chrysoprasius*. This is the name given it when it has a large admixture of yellow, and its green is a pure but a very pale one.

And, finally, De Boot mentions another species, as he calls it, of *prasius*, which was more opake than the rest, and had but little green, and a large admixture of white among the yellow; but this is in reality only a species of nephriticus.

The finest of the *prasii* are found in the island of Ceylon; but there are many of them in New Spain. We have them also from Silesia and Bohemia; but these are very poor ones. *Hill's* Hist. of Foss. p. 597.

PRECATORES, in church history, a sect of heretics, who under the pretence of praying always, refused to work. *Hofm.* Lex. Univ. in voc.

PRECEDENCY. See the articles PRECEDENCE, *Cycl.* and CEREMONIAL, *Suppl.*

PRECIPITATION, *(Cycl.)* in assaying, is the separation of any part of a compound body while melting in the fire, or when cooling from fusion from the rest of the mass, in such manner that it sinks to the bottom, while the remainder continues at top and makes the surface. The heavy part thus *precipitated* from the rest, is called the *regulus* of that body.

This is an operation which almost always requires the addition of such ingredients as serve to take away the mutual connection and coherence of the parts of the body to be separated; that is, such as have a menstrual virtue, and keep others in a state of dissolution. For instance, the reguline part of antimony, and mineral sulphur, dissolve each other mutually, and constitute crude antimony; nor can they be separated from each other by fire alone without destroying the regulus; but if you add iron, copper, silver, &c. which are more thoroughly penetrated by sulphur, and are thus reduced to the state of ore, then the regulus of antimony is freed of its sulphur, and sinks to the bottom, as it is heavier than the additional bodies, when joined to the sulphur.

Such a *precipitation by fusion* happens in vitrifications, scorifications, and coppelings, while one part of the body turns into dross, or *scoriæ*, and the other metallic part, if there be any, keeping still its metallic form, is collected at the bottom of the spherical vessel. Therefore silver and gold, which are hardly subject to a perfect vitrification, constantly remain and shew themselves in their own form; and on this account, tho' they were in ever so small a quantity in a *coppel*, they always shew themselves very clearly to the eye when the *scoriæ* are absorbed; whereas so small a regulus of the other metals would have been as it were buried and hidden under so great a quantity of *scoriæ*.

Nor is *precipitation by fusion* less necessary to obtain almost all the other metals, which on this account are called less perfect, unless perhaps you except a very small quantity of native metal, which nevertheless can scarce be properly called pure. Beside, they are all to be had either in form of earth, or of that of a solid ore. In the first case you may make a glass by a bare fusion: in the second, if the sulphur and arsenic, which, together with the metallic part, constitute an ore, are dissipated in roasting; the ore destitute of the oily phlogiston, becomes glass in a pure fire, which glass may be mixed with unmetallic stones and earths; but by adding a phlogiston or inflammable principle to it, this metallic glass is again reduced to its metalline form; and so long as it keeps under this form it cannot be united with the glass of the other species, but sinks to the bottom of it, except only a very small quantity of it, which is detained by the clamminess of the glass. The *precipitating* body in this case, therefore, is truly the phlogiston, or inflammable principle: any body that takes away the connection, by the removal of which a *precipitation* is made, is properly called the *precipitating* body. *Cramer's*. Aff. p. 187.

Precipitation of solid bodies from fluid menstrua, is performed either by extracting, or evaporating over a gentle fire the dissolving menstruum out of the dissolved fixed body, or by adding such a body, as is greedily dissolved by that menstruum: as if one metal dissolved by an acid is *precipitated* by another metal, or by an alkaline salt: for instance, silver dissolved in aqua fortis is *precipitated* by copper, copper by iron, iron by zink, and all metals and semi-meals, either partly or entirely by pot-ashes, volatile, and urinous salts.

A *precipitation* is also made by pouring on a solution, such things as either cannot dissolve the body in hand, whether alone, or joined to a menstruum that contains the said body; or dissolve it in another manner; or in a lesser quantity than if the menstruum had been used pure. In the first case a total *precipitation* is performed, as may be seen in the *precipitation* of silver out of aqua fortis, by means of spirit of salt. In the second a great deturbation and *precipitation* is made, but a second solution soon follows, as it happens when iron being dissolved in aqua fortis, you add to it in a proper manner a liquor perfectly free from alkaline fixed salt; but then there remains usually a certain part which is not perfectly dissolved a second time. In the third case there is but a partial *precipitation* made. You have an instance of this, if mercury dissolved in aqua fortis, and the menstruum thoroughly saturated with it, is *precipitated* either by common salt, or sal armoniae, or by their acid spirit. A *precipitation* is also sometimes made only by adding a large quantity of fair water to dilute; such is that made on the regulus of antimony dissolved in spirit of common salt, or in aqua regia, when a large quantity of cold water is poured on this solution; for these menstrua do not dissolve this semi-metal, unless concentrated.

All these *precipitations* are promoted greatly by a gentle heat, by means of which the *precipitating* body enters more easily into the menstruum, and a considerable quantity of water is next necessary to dilute with, except in the *precipitations* of the first kind; for most commonly the more concentrated dissolutions assume the consistence of a paste so soon as the *precipitating* body is added to them, which hinders this from mixing equally with the solution. Id. ibid. p. 196.

Boerhaave makes the following observations on the different manner in which *precipitation* is performed by several different agents.

Thus 1. By water poured on oils dissolved in alcohol, where the liquor turns milky.

2. By water poured to solid resins dissolved in alcohol, where also the liquor turns milky.

3. By water in the distillation of oily spirits, if any water run after the spirit is drawn off.

4. By acids on acids; thus silver and mercury are *precipitated* out of spirit of nitre, in which they had been dissolved by adding spirit of salt.

5. By metals with metals, and other bodies. Thus for example, dilute an ounce of silver dissolved in spirit of nitre, with

with twelve times the quantity of rain water; put polished plates of copper into this liquor, and the silver will be precipitated and the copper dissolved: then put this solution of copper into another glass, and add to it polished plates of iron; the copper will be precipitated and case over the iron; finally the copper falls to the bottom, and the iron dissolves. Pour this solution of iron into a fresh glass, and drop upon it oil of tartar, per deliquium; the dissolved iron immediately falls to the bottom, and the alkali unites with the acid, and regenerates true nitre, after so many changes.

Thus does this salt travel from one body to another almost unaltered, tho' it is more attracted by one than another, till at length it rests in that which in this respect is the strongest, and is only thence expelled when oil of vitriol is poured upon the nitre thus regenerated. On these two principles *precipitation* depends, and is the true, and often abstruse cause of numberless wonderful operations, both in art and nature. Take a grain of white or red *precipitate*, rub it upon a polished and heated copper-plate, and wherever the matter has passed the copper will immediately look like silver; for the copper attracts the acid of the nitre from the calx of the mercury, and thus presently makes an amalgam upon the surface of the copper, and then acquires a silver colour.

6. Alkalies often *precipitate* things dissolved by acids. This happens frequently, but not always, nor in perfection: alkali *precipitates* copper dissolved by an acid, but the copper is afterwards dissolved by a salt made of the two.

7. Acids generally *precipitate* things dissolved by alkalies; but in this case also there are some processes which shew us exceptions.

8. Sharp salts, without being changed, and lying perfectly concealed, have strange and unexpected effects by means of *precipitation*. If an ounce of luna cornea, which is perfectly scentless, insipid, and unactive, and affords no sign of acrimony in the fire, be ground, and united in a strong heat in a glass retort with half an ounce of inodorous and perfectly insipid regulus of antimony, there instantly arises an extremely strong poison, or an exceedingly corrosive butter of antimony, the exhalation of which proves mortal. We see in this one instance how dangerous the art of mixing is, and with what care we ought to go about the compounding of bodies. *Boerh.* Chem. P. II. p. 338.

PRECIPITATE (*Cycl.*)—The different absorbent salts which are commonly used for the *precipitations* of metals, from their solutions in acid menstrua have no effect upon those metals as to the colour of the *precipitate*; but when the solution is clear and limpid, and the matter left on the evaporation of it would have been white, the *precipitate* in this case, by whatever salt it is made, will be white also. And when that solution has any particular colour, whether it be that of the metal alone, as in solutions of gold; or a colour that is the result both of the metal and menstruum, as is the case in the solutions of copper and iron, the *precipitate* obtained from the solution will always be of the colour the solution was of, whatever was the salt employed to make it. Tho' this is, however, the case in regard to the metals in general, yet it is to be observed that mercury dissolved in spirit of nitre, or reduced to the state of corrosive sublimate, and afterwards dissolved in water, affords phænomena perfectly different from all these: for tho' it gives no colour to the menstruum in which it is dissolved, but lets it remain limpid; and if the solution be evaporated to a driness, leaves only a white residuum, in the manner of the solutions of silver, tin, or lead; yet instead of giving a white *precipitate*, in the manner of those metals, it affords a differently coloured one, through a great many varieties, according to the nature of the salt used to make it. As mercury is soluble in more acids than one, and as the experiments made on one of the solutions of this metal often have different phenomena from the same experiments made on other solutions, Mr. Lemery, who has employed himself very nicely on this subject, chose the solution in spirit of nitre as the basis of a long series of experiments.

As this solution was a mixture of two bodies, it was first necessary to consider them separately, as to their colours. In this examination it is to be observed,

1. That spirit of nitre, when first made, and while it yet contains a great quantity of fiery particles, is of a red colour; and that afterwards, as these gradually evaporate and fly off, the spirit by degrees loses that colour.

2. That crude mercury, when exposed a long time to the action of the fire, becomes of a red colour.

3. That when a simple solution of spirit of nitre is evaporated, and the matter which remains after the evaporation is calcined, it changes from its white colour, which it had at first, to red, after passing through all the shades of yellow. Now since, in the change of its state from the white to the red colour, the mercury loses a great part of the acid particles which it had carried away from the solution, we might at first be apt to conclude, that its change of colour proceeded from this; but on the contrary, experience proves, that of whatever quantity of its acids mercury is divested after solution, provided that no fresh particles are admitted in their room, it always continues white so long as it contains acid enough to preserve it in this form, or keep it in the condition of a *precipitate*.

As we know that fire is itself a fluid of a peculiar nature, and which has a power like other fluids of insinuating itself into the pores of the other bodies, and there, like them, preserving its essential properties; and as we also know, that the mixture of the particles of fire, either singly with mercury, or with spirit of nitre, gives to either a red colour; it is very natural to conclude, that the quicksilver, when it has been penetrated by the acid of spirit of nitre, and afterwards acted upon by calcination, is not changed from white to yellow, and from yellow through all its changes to red, by any other means than by the particles of fire which introduce themselves into the *precipitate* as they drive the acid particles out: and this is evinced the more clearly by this experiment, that if fresh acid be added to this *precipitate*, now become red, in such proportion as to divest it again of the fiery particles, and lodge its own in their places, then the whole loses its red colour, and either becomes colourless, or else white as it was before.

The common white *precipitate* acted upon by a slow fire, thus loses its white colour, and advancing through all the degrees of yellow, becomes at last red, as in the former instance; but if, instead of this slow heat, there is a stronger fire employed, and that continued so long as to raise this *precipitate* in a matrass into the form of a sublimate, in this case it preserves its white colour, notwithstanding the violence of the fire and the loss of its acid particles, which in this process cannot but be very considerable; nay, and tho' the sublimation be repeated several times, the whiteness of the matter will not be altered by it. From this observation it may be seen, that when nothing is added to the matter in the place of the acid particles which are driven off, it suffers no change of colour by their loss; and that in cases where larger fires are used, and consequently the fiery particles are driven through the body of the *precipitate*, there is no change of colour made in it by them; but that in order to make this change of colour, the fire must be slow, and the particles must be driven in with a force that is not sufficient to drive them out again, and consequently must remain there. It is evident, that the deprivation of the acids alone, does not change the white *precipitate* red; because in this case, where there is no such change of colour, there is, however, a manifest deprivation of a great part of those acids; since there are always many globules of revived mercury found among the masses of the sublimate.

Experiment proves, that mercury becomes more or less able to resist the force of fire, as it is more or less highly impregnated with acids: and hence the same degree of fire applied to two quantities of mercury, differently charged with acids, shall have different effects, and shall give a red colour to that which is so sated with acids that it will not be raised in sublimation; and the other, which is less charged with them, shall be sublimed and left white. The white *precipitate* made in the common way, is at the utmost only able to bear a much smaller degree of fire than that necessary to make the common red *precipitate*; and crude mercury itself can only bear a much weaker than either, as is seen in the making the common calcined mercury, improperly called *precipitate per se*.

There is this, however, very remarkable in the making this calcination, that after the mercury has been calcined some time with the necessary gentle heat, it becomes able to bear a much stronger degree than it could at first. This is exactly the contrary of what is found in making the common red *precipitate*; in doing which the fire must necessarily be gradually diminished, for the same degree of fire which it at first bore, nay, which was necessary to it, if continued, would certainly sublime and evaporate it. The explanation of this is, that in each case the mercury becomes able to resist the force of the fire in proportion as it receives particles which increase its weight. This both fire and the acid are capable of doing to it; but the acid does it in so greatly superior a degree, that while in the one case crude mercury, receiving particles of fire into its body, becomes by their means capable of resisting a stronger heat; in the other, these particles of fire being only received in the place of acid ones before dissipated, which added much more to its weight than they, it becomes much less able to resist a violent heat by the change, and gradually, as it receives the fiery in the place of the acid particles, requires the heat to be decreased, otherwise it must be evaporated.

In fine, we see that crude mercury requires a long time to be reduced into a red powder by means of calcination; whereas the same mercury, when loaded with acids, may be converted into this red powder in a few hours; the one bearing a tolerably strong heat, the other only a very weak one.

It appears that the mercury loaded with acids yields, therefore, a more easy access to the particles of fire than the crude; and what proves this, and evidently shews that the acids accelerate the effect of the fire on this body is, that if the common white *precipitate* be exposed to the same gentle degree of heat with crude mercury, it becomes red much sooner; and as the difference here is only, that the one is plain mercury, the other mercury penetrated by acids, there can evidently be no reason for the latter turning red sooner, but its being so penetrated.

After thus examining the effects of fire on solutions of mercury, this author proceeds to examine the effects of the different

ent falts on the folution in aqua fortis; and in thefe difquifitions it appeared, that thofe falts which gave the mercury a yellow or a red colour, only produced this effect, as they had been expofed to a longer or a fhorter calcination, by which their acids had been driven out, and particles of fire received in their places, and retained there, infomuch that thefe all heat water on being put to diffolve in it, as they contain a larger or fmaller quantity of thefe particles. Now as it is evident that thefe falts give a heat to water, by no other means than by the fiery particles they contain, it is very naturally fuppofed, that they give the yellow or red colour to the diffolved mercury, by the fame means as we know that thefe are the colours that fire itfelf gives to this body. Thefe falts, before their calcination, make no fuch change in mercury: and it appears, that they act upon it as alkalies only, or bodies which have paffed a violent calcination; and that the fiery particles they contain make them act upon it as fire would; and upon the whole, that fire and alkalies produce the fame effects on the folution of mercury in aqua fortis.

On the other hand, thofe falts which have not been expofed to the action of fire, and which cool, inftead of heating the water they are diffolved in, or fuch as having been calcined have acquired but little of an alkaline nature by the procefs; that is, have collected few particles of fire in the place of the few acid particles which they have loft; thefe do nothing to the diffolved mercury but carry off a part of its acids, its whitenefs being not at all affected by them: nay, even falt of tartar, which is a very powerful alkali, if there be acids mixed with it to drive off the fiery particles it contains, and place themfelves in their room, becomes wholly like one of thefe falts, and makes no change in the colour of the mercury.

In fine, the volatile falts, if they are pure, always give a white *precipitate* from the folution of mercury; but as thefe falts ufually contain a large portion of oil, this generally becomes feparated from them in the operation, and mixing itfelf with the *precipitate*, makes it of a mixt colour between its own natural white and the natural colour of the oil. As thefe oils in the falts have paffed a ftrong fire, they are ufually burnt, and naturally of a blackifh colour; and therefore the refult of their mixture, with the white *precipitate*, is a dirty grey. On the other hand, when urine is ufed, as the oily matter attending its falts has not been burned by fire, and as it naturally, by becoming exalted, by fermenting with the folution, acquires a deep blood-red colour, the confequence is, that the *precipitate* is of the middle colour between this blood-red and its own natural white, and fhews itfelf of a pale damafk rofe colour.

Thefe are the effects of the abforbent falts, when added fingly to the folution of mercury; the next thing to be enquired into is, how they act when added one after another to the fame quantity of the folution? When we have given this folution a yellow colour, by adding falt of tartar, which, as an alkali, occafions that effect; if we afterwards pour upon this fpirit of fal armoniac, or other volatile falt diffolved in phlegm, and raifed by diftillation, the yellowifh or reddifh colour immediately difappears, and the whole becomes of a dirty greyifh colour, which afterwards becomes blackifh; but if oil of tartar, per deliquium, or any other powerful alkali be added, it does not again deftroy this colour, and produce what it naturally would, if fimply mixt with the folution, but only extends the dark or blackifh colour which the mixt matter before had received from the fpirit of fal armoniac.

If falt of tartar, or any other fixed alkali be added to a folution of mercury, which has before been rendered white by a mixture of common falt, or any other falt that has little alkali in it, the liquor becomes immediately yellow, and that colour remains unalterable by any frefh addition of falt whatever. Salt of tartar is therefore in this cafe to the other falts that the fpirit of fal armoniac is to falt of tartar. If oil of tartar and fpirit of falt be alternately added to a folution of mercury, the folution becomes alternately yellow and white, according to the laft liquor that was added; fo that thefe two oppofite liquors feem to be of equal force, each making the folution of the colour it naturally gives, when fuperior to the other in quantity. Thus far, however, only two different liquors have been mentioned; it is poffible to employ feveral others in the fame manner one after another, and by that means to produce many more changes of colour in the folution. All that is to be taken care of in this experiment is, that the weaker liquors be ufed firft, fince otherwife they cannot produce any change; and what is to be concluded from the whole is this: 1. That mercury when it is penetrated by acid fpirits, is naturally of a white colour. 2. That when it is changed to a red or yellow colour, it is wholly owing to particles of fire introduced into it. 3. That it never changes from white to red, or from red to white again, otherwife than by receiving or parting with the fiery particles it had before received. 4. That when the folution acquires a colour, the mercury lofes its acids, or part of them. 5. That every time it changes its colour it either lofes it acids, or gains frefh ones; and that this lofing and gaining its acids, is a condition without which the mercury can neither admit, or throw off the particles of fire. 6. That when an abforbent does nothing to the folution but take away the acids, without communicating any thing to the mercury in their place, it always gives a white colour to the *precipitate*, or to fpeak more properly, it makes the *precipitate* appear in its proper colour. 7. That it makes fome other colour appear, when in the place of the acids, of which it has robbed the mercury, it gives it other fubftances which colour it according to their nature and quantity. 8. That in feveral abforbents calculated to produce feveral colours, that which is the moft powerful alkali is always capable of deftroying all the reft; but that there does not neceffarily follow a change of colour, on the liquor becoming altered from a lefs alkaline to a more ftrongly alkaline nature. 9. That a liquor of a very ftrongly alkaline nature, added to the folution after one which was a weaker alkali, will make no change in the colour of the liquor, if it have no other effect than the abforbing more of the acids from the *precipitate*, and does not give it other particles in the room of thofe acid ones which it takes away; and, finally, that weak acids are capable of changing the *precipitate* from red to white, but that ftrong ones utterly deftroy all colours. Mem. Acad. Par. 1714.

PREDY, a fea word fignifying the fame as *ready*. Thus, *predy the fhip*, or *predy the ordnance*, is as much as to make things ready for a fight. *Predy the hold*, is to lay or ftow every thing there in its due order and proper place.

PREGNANCY, *graviditas*, (*Cycl.*) the ftate of a woman going with child. This is a time in which women fuffer many diforders, which tho' no way to be cured abfolutely but by childbirth, yet may be greatly mitigated by medicines. Before any one venture to do any thing, however, in thefe or the like cafes, it is very neceffary to be perfectly affured, whether the patient is with child or not; and this is known by the following fymptoms, in cafes where there is no occafion for diffimulation, or no other diftemperature joined with this; but when the woman chufes to conceal it, and there is a complication of diforders, the utmoft proofs amount but to prefumptive ones.

The ftoppage of the menftrual difcharges is the firft fign of it, provided that there be no other apparent caufe. But this, tho' the moft plain and obvious fymptom, is by no means a certain one; for a fuppreffion of this kind may happen from latent caufes. A fecond fymptom is, a particular naufea at the fight of meat, or even the fmell of it, while the perfon is otherwife well in health, and can eat heartily of other foods. A third fymptom is, a fwelling of the belly; which appears regularly round or globofe, not irregularly protuberant, as is the cafe in diforders of the liver, and other vifcera. This fwelling, alfo, increafes placidly, and without the legs fwelling, or any other fymptom, if the perfon is otherwife in health. After this, the twentieth week of *pregnancy* gives the moft certain of all the figns, the motion of the fœtus; but this is to be carefully diftinguifhed from motions of the bowels in flatulencies, which often fo much refemble it as to deceive the unwary.

If the mother has a mind to hide the fymptoms, the thing may, however, ufually be found out at this period; for if a cold hand be laid upon the belly when warm, or a warm hand when it is cold, the fœtus ufually foon ftirs, and the very figure and appearance of the belly will give very probable affurances to a perfon accuftomed to fuch infpections. In cafes of a certain conception, a living fœtus is only to be diftinguifhed from a mole or falfe conception by its moving; therefore when a perfon grows toward the full time, without ever perceiving the child to ftir, it is very much to be fufpected that it is a mole; which alfo is the more probable, if the menftrual difcharges have come on at times and irregularly, during the time, and the fwelling of the belly be irregular, the woman fubject to violent flatulencies, and efpecially if fhe go beyond the natural period of nine months.

Thefe fymptoms are not all, however, to be expected in every *pregnant* woman; for many of the laborious people of the lower clafs of life, go thro' their whole time in the midft of fatigue and trouble, and that without any of thefe fymptoms; fo that they are in a great meafure to be attributed to the courfe of life, not the courfe of nature, in the *pregnant* women of better fortunes. Thofe women are moft fubject to them who are of a tender and delicate frame, and thofe who are of a plethoric habit, an idle life, or given to intemperance, or fubject to paffions of various kinds, fear, anger, grief, or the like.

Thefe are the more natural and lefs troublefome fymptoms of *gravidation*, but this time is frequently attended with others more troublefome or hurtful, which art is able in fome degree to mitigate. Some are fubject to violent hæmorrhages at the nofe, which are to be treated in the common way, and are ufually as eafily cured as any other complaints of that kind. In others the hæmorrhoidal difcharges are very large during the time. Thefe are to be affwayed by giving powders of nitre, cinnabar and crab's eyes, once or twice a day. Some are alfo fubject to an hæmorrhage of the uterus itfelf, but this very rarely happens; when it does it may be owing to two caufes, and therefore appear in two manners. In the

firſt it flows as in the common way of the menſtrual diſcharges, during the firſt months of *pregnancy*, and by that means greatly diſturbs the regular calculation of the time. In the other caſe it ſtops during the firſt months, but comes on again about the middle of the time, or later than that, and in this caſe it uſually continues regularly to the time of delivery; both theſe caſes bring on great danger of miſcarriages. In theſe caſes nitrous cinnabarine and abſorbent medicines are to be given; to theſe are to be added corroborating ones, and bleeding in the arm muſt never be omitted.

Head-achs often alſo attend women during their *pregnancy*: theſe are principally owing to occaſional cauſes; ſuch as violent emotions either of the body or mind, an improper cooling of the lower parts of the body, or the drinking ſpirituous liquors. The method of taking off this troubleſome ſymptom is, by giving the attemperating and nitrous medicines, with laxatives of the moſt gentle kind, and externally the head ſhould be rubbed with ſpirit of wine and camphor, if the perſon can bear the ſmell of it, which often in this caſe they cannot.

A wearineſs and laſſitude of the limbs is another very common and very troubleſome accident attending *pregnancy*, and is to be remedied by proper bleedings and gentle exerciſe; and if theſe fail, the nitrous powders before given may be added to quiet the emotions of the blood, and this uſually takes effect.

A dry cough and difficulty of breathing are alſo not unfrequently attendant on this ſtate: theſe require the ſame methods; but when the difficulty of breathing comes on after meals, the ſaline and digeſtive powders may be given in ſmall doſes; ſuch as the vitriolated tartar, with the nitrous and abſorbent powders; and when it comes on only in the latter months, and ariſes merely from the preſſure of the diſtended uterus, there is no cure but patience till the time of delivery; when the ſymptom always goes off of itſelf on the ſubſiding of the womb. *Junk.* Conſp. Med. p. 701.

The French memoirs give us an account of a very unhappy ſtate of *pregnancy* in a young woman of ſeventeen, attended with ſymptoms not common to that ſtate. The child lay on the right ſide, and grew to ſo conſiderable a ſize that ſhe could not ſtir; it died ſoon after, and was taken from her dead and in ſeparate pieces. In the latter months of her *pregnancy* ſhe was troubled with a terrible oppreſſion in the breaſt and difficulty of reſpiration, attended with violent palpitations of the heart: her delivery gave her no eaſe as to theſe ſymptoms, but they continued increaſing in violence for five years. In this time, as ſhe was young ſhe grew in height, and had two children, which both lay on the right ſide alſo, and of which ſhe was delivered without any particular bad ſymptoms. After theſe five years the bad ſymptoms of her diſeaſe became at a ſtand, and in her thirty-ninth year ſhe died.

The body being opened after her death, the round and the broad ligament of the uterus were both found much ſhorter on the right ſide than on the other, and were more compact and thick on that ſhort ſide. The uterus was larger than uſual, and inclined a little to the right ſide; and the great lobe of the liver, which ought to be hollow behind, convex before, and narrow and ſtrait at the bottom, large and thick at the top, and wholly included in the cavity of the belly, was in this ſubject of a conic figure, nine inches long, and four inches broad at the baſe, which was its lower part, and two at the point; and half its quantity was depoſited in the cavity of the breaſt, and all the parts on the ſame ſide. The kidney, the diaphragm, and the lungs, appeared, as well in regard to one another as to the neighbouring parts, to have been all conſiderably puſhed upwards by the matrix. The too great force of the ligaments of the uterus on the right ſide, had drawn the uterus itſelf to that ſide, and determined the fœtus to that part; and unhappily that had been particularly large, and had extended the influence of its preſſure upon the viſcera above it, even to the lungs. The duration of the ſymptoms was owing to this, that the parts having been diſplaced for a long time together during the latter months of the firſt *pregnancy*, could not reſtore themſelves to their places again, even when the obſtacle was removed; ſo that the ſymptoms continued, even tho' the firſt cauſe was removed; and the growth of the young woman only increaſed them. Mem. Acad. Par. 1709.

The miſcarriage of *pregnant* women is principally owing to a plethora, and is moſt frequent with young plethoric women, in the firſt months of their firſt *pregnancy*. There are, however, ſeveral other cauſes which concur to it; ſuch are, any violent paſſions of the mind, as ſudden anger, fear, or the like; an habitual great diſcharge at the time of the menſes, a high-ſeaſoned diet, with much wine or other ſtrong liquors; the taking of ſtrong purges, or violent emetics; diarrhœas, eſpecially when of long continuance and of the aromatic kind, as they drain off the nouriſhment from the fœtus; a teneſmus, or violent motion to ſtool, and hence the uſe of ſtimulating glyſters may alſo bring on abortion; as alſo any commotions of the body, ſuch as running, leaping, the carrying heavy burthens, falls, or blows on the abdomen: a too frequent uſe of venery may alſo occaſion it, as may the effect of ſtrong emmenagogues, copious bleeding in the foot, the ſmell of burning oil or any other ſtinking ſubſtance, nephritic complaints, cachexies, a fluor albus, or other diſorder of the womb; the taking opiates, and the death or great debility of the fœtus while in the womb. The beſt methods of preventing abortion, are the uſe of the attemperating and particularly the nitrous medicines after every commotion of the blood; bleeding at proper times, corroborating medicines, and the milder carminatives; and to theſe are to be added a temperance in diet, and placid motion of the body. Egg-ſhells are by ſome greatly recommended, and by others the ſtones of reſins, which are, indeed, manifeſtly aſtringent.

Coſtiveneſs in the time of *pregnancy* is very common, and is uſually owing to the want of drinking and exerciſe; ſometimes, indeed, it is owing to the immediate preſſure of the womb upon the rectum; but this caſe is known from the others, as it is always attended with a teneſmus. This complaint is to be relieved by a lubricating diet, the drinking more liquids than before, and the uſing placid motion of the body, or gentle exerciſe. Gum ammoniacum is alſo found a very uſeful medicine in this caſe, and ſometimes gentle infuſions of ſenna are neceſſary; but theſe can only be given in very ſmall doſes. Some uſe ſuppoſitories that are not acrid or pungent, and others glyſters of water-gruel.

Flatulencies are another very frequent complaint with *pregnant* women: theſe are removed by the milder carminatives, ſuch as, orange-peel, pimpernel-root, and the ſeeds of aniſe, ſweet fennel, &c. taken in powders or in decoctions.

Diarrhœas, in *pregnant* women, are uſually from the ſame cauſes with thoſe in other perſons; but they require in this caſe a very peculiar regard, as they, when long continued and accompanied with a teneſmus, uſually bring on abortion. They are to be gently reſtrained, and finally ſtopped, in the following manner: ſtrengthening, carminative and ſtomachic medicines are to be given, ſuch as candied orange-peel, preſerved ginger, calamus aromaticus, galengals and zedoary, and the marmalade of quinces; and while theſe are taken internally, balſams and ſtomachic plaiſters applied to the ſtomach have alſo a very great effect.

The fluor albus. This is a complaint that very rarely affects women with child, eſpecially if their huſbands be honeſt; but when it does, it is very difficult of cure, becauſe the purging medicines neceſſary to be given in it are by no means to be allowed of in the time of *pregnancy*. In this caſe it can only be reſtrained by the uſe of correctives, depuratives, and carminatives: of this kind are infuſions of the bitter herbs, with pimpernel-root, balm, ſouthernwood, and white dead nettle-flowers; or theſe ingredients may be made into powders, and taken in red wine.

Beſides all theſe complaints, women in their *pregnancy* are ſubject to ſeveral others which depend upon the mere weight and preſſure of the uterus. Of this kind are:

Pains in the loins and back. Theſe are principally felt in the laſt months, when the belly is greatly ſwelled and drawn forwards; in others, at the ſame period, the belly itſelf is pained, and looks red in many places, as if it threatened to burſt. Theſe complaints are made worſe by all motion, and they admit of no cure but child-birth, which immediately takes off the whole pain.

Varicous tumors of the legs. Theſe are alſo very common and very troubleſome, and in phlegmatic habits have alſo very frequently œdematous tumors joined with them; and in other perſons livid marks appear upon them, ſuch as are ſeen in others after bruiſes. Theſe diſtemperatures of the legs attend *pregnant* women at all times from the ſecond month to the time of delivery, and are owing to the preſſure of the uterus upon the iliac or crural veſſels. Theſe always go off on delivery, but in many perſons return again at every *pregnancy*: in ſome caſes they are ſo ſlight as not to be worth regard in others they are very violent and painful; theſe are to be treated in the following manner: the common antiſpaſmodic powders are to be given internally once or twice every day, and externally, a moderate bandage, with camphorated medicines and friction; and if theſe fail, a liniment made of lime-water, oil of elder, and ſugar of lead, will be found of great ſervice; and when the perſon is delivered, gentle ligatures are to be uſed all up the leg, from the ankle to the knee. In order to prevent theſe tumors for the future, early in the time of *pregnancy* the perſon ſhould be blooded, the bowels are to be kept from coſtiveneſs; and it is a thing of the greateſt conſequence, that the perſon uſe herſelf to ſit upon a high ſeat, the low chairs in which *pregnant* women uſually love to ſit making the belly preſs greatly more on the crural veſſels than it would otherwiſe. Too much exerciſe alſo is to be avoided, and particular care taken that the womb is well cleanſed before the month of a former lying in is over.

Frequent deſire of voiding the urine often attends, and is very troubleſome to *pregnant* women; but eſpecially in the latter part of their time, particularly in the laſt weeks: if it happen ſooner, as it ſometimes does, it is owing to the womb's hanging too much downward, from a laxity of the ligaments. This is a complaint of no ill conſequence, and therefore, tho' troubleſome, is to be borne with patience, delivery being its proper cure.

A Strangury and temporary ſuppreſſions of urine happen alſo frequently

quently to *pregnant* women. In these cases powders of nitre and cinnabar are to be given internally, and externally emollient cataplasms are to be applied warm till the disorder ceases.

Hæmorrhoides. These in *pregnant* women often swell into a sort of bladders, and are attended with a violent burning pain, and sometimes with an ulcerous erosion, and are usually a very troublesome complaint to persons of plethoric habits. They are to be cured by giving internally nitrous and other attemperating medicines, and applying externally the unguentum linariæ, made of the herb toad-flax, cut and boiled in lard. A decoction or extract of yarrow is also a good medicine.

Swellings of the feet are another of the troublesome complaints that attend *pregnant* women. These, when they are confined to the feet, or do not extend above the knees, are of no great harm; but they sometimes reach up to the abdomen, and there leave the symptoms of an ascites: but even in this case, it is best to let the tumor alone during the time of *pregnancy*, or at the utmost only to attempt mitigating and allaying its symptoms; for the cure requires such medicines as cannot be safely given at that time. The patient must avoid standing as much as possible, and after delivery the cure is to be attempted in the common way. When women in their *pregnancy* lose their flesh, and become extenuated and thin, the child is usually found to be the lustier and more robust for it: the woman in this case should feed on jellies, and other the most nourishing foods, and should use very little exercise, avoiding all fatigue of body and mind. Others, on the other hand, are subject to grow remarkably fat during their *pregnancy*: these generally bring forth small and lean children. Women to whom their fat grows troublesome in this time, should bleed, use moderate exercise, a thin diet, and now and then take a very gentle dose of some laxative medicine.

Many are very weak and subject to frequent faintings during *pregnancy*: these should take at times a gentle dose of some laxative medicine, and in the intermediate days, the strengthening and stomachic medicines, with the milder carminatives.

A voiding of the waters too soon always threatens abortion, or an untimely delivery, which are to be guarded against by strengthening medicines of all kinds. Many women during *pregnancy* are troubled with large brown spots, or lichenes, in the neck and face: these principally happen to persons of bilious habits, and are in some attended with a continual paleness, in others with frequent flushings of heat and redness: the good women apply many remedies to these, but they are much better wholly let alone; for they always go off of themselves after delivery.

The too great motion of the fœtus is a complaint not uncommon with *pregnant* women; but this is principally owing to themselves, and is brought on by the violent passions of the mother, especially those of anger: the keeping the abdomen too hot will also occasion this, and sometimes it is owing to some indisposition of the fœtus itself. If any medicines are to be given in this case, it must be the attemperating ones, and such as can correct the acrimony of the bilious juices; nervous epithems may also be externally applied, and the person is to be kept in as tranquil a state as possible, both as to bodily motion and the passions of the mind.

The child's kicking in the uterus is a complaint very frequent in the last months of *pregnancy*, and in persons of tender habits it often occasions tears, and sometimes faintings. Some suppose that this threatens abortion; but this is wholly erroneous, for the fœtus has no power of contributing to its own birth. This is a symptom for which there is no remedy but patience, but it goes off before the time of delivery.

Weakness of the fœtus is known by its feeble motion in the womb, and usually depends on the bad constitution of the mother, or else on her having been subjected to violent frights, or to great sorrow. Internal medicines of the strengthening kind are proper in this case, and externally, balsamic and aromatic plaisters may be applied.

The secundines sometimes concrete or grow to the uterus, out of their proper order and place: this is a disorder we have but very slender opportunities of guessing at, and is principally caused by too much sitting still during the latter part of *pregnancy*. When this is suspected to be the case, internal medicines are of no use; and the externals are only the fat of tender animals, or spirit of wine impregnated with oils of annise or caraway, frequently rubbed in on the belly.

The winding of the navel-string about the neck of the child is often a very unhappy accident and proves fatal to it: the good women suppose this to be owing to the mother's reaching upwards, and straining her arms above her head near the time of her delivery; but this is an idle opinion, and the case is owing to no sudden accident, but is probably an unlucky turn of the string from the beginning. *Junker*'s Consp. Med. p 708. See LYING-*in*.

PRENANTHES, in botany, the name of a genus of plants, the characters of which are these: the flower is of the composite kind; the common cup is of a cylindric figure, and has a wide mouth; there are five equal squammæ, and three unequal ones, which are smaller, and placed at the base. The flower is compound, not imbricated; it is composed of equal flowers of the hermaphrodite kind, placed in a single circle; each single flower is composed of one petal, and is ligulated, truncated, and divided into five segments at the edge; the stamina are five very short and capillary filaments; the antheræ are cylindric and tubular; the germen of the pistil is placed below the flower; it is small; the style is capillary and longer than the stamina; the stigma is bifid and reflex; the cup, after the flower is fallen, joins its several segments lightly at the top; and the seeds are single, of a cordated figure, and winged with a slender downy filament; the receptacle is naked. There is one species of this plant in which the down has a pedicle. *Linnæi* Gen. Pl. p. 374.

PREPARATION (*Cycl.*)—PREPARATION, in anatomy, is used for the art of preserving the parts of animal bodies for anatomical uses.

It is also used to signify the parts themselves so preserved. Mr. Monro has given us an essay on the method of *preparing* and preserving the parts of animal bodies for anatomical uses. Med. Ess. Edinb. Vol. III. Art. 10.

The manner of preserving anatomical *preparations*, is either by drying them thoroughly in the air, or putting them into a proper liquor.

In drying parts which are thick, when the weather is warm, care must be taken to prevent putrefaction, fly-blows, insects, &c. This is easily done by the use of a solution of corrosive sublimate in spirit of wine, in the proportion of two drachms of sublimate to a pound of spirit: the part should be moistened with this liquor as it dries, and by this method the body of a child may be kept safe even in summer. Dried *preparations* are apt to crack and moulder away in keeping; to prevent this their surface should be covered with a thick varnish, repeated as often as occasion requires. Med. Ess. Edinb. abr. Vol. II. p. 8.

Tho' several parts *prepared* dry are useful, yet others must be so managed as to be always flexible, and nearer a natural state. The difficulty has been to find a proper liquor for this purpose. Mr. Monro says, the best he knows is a well rectified colourless spirit of wine, to which is added a small quantity of the spirit of vitriol or nitre. When these are properly mixed, they neither change their colour nor the consistence of the parts, except where there are serous or mucous liquor contained in them. The brain, even of a young child, in this mixture grows so firm as to admit of gentle handling, as do also the vitreous and chrystaline humours of the eye. The liquor of the sebaceous glands and the semen are coagulated by this spirituous mixture; and it heightens the red colour of the injection of the blood vessels, so that after the part has been in it a little time, several vessels appear which were before invisible. If you will compare these effects with what Ruysch has said of his balsam, you will find the liquor above mentioned to come very near to it.

The proportion of the two spirits must be changed according to the part *prepared*: for the brain and humours of the eye, you must put two drachms of spirit of nitre to one pound of spirit of wine. In preserving other parts which are harder, thirty or forty drops of the acid will be sufficient; a larger quantity will make bones flexible, and even dissolve them. The part thus preserved should be always kept covered with the liquor, therefore great care should be taken to stop the mouth of the glass with a waxed cork and a bladder tied over it, to prevent the evaporation of the spirit; some of which, notwithstanding all this care, will fly off; therefore fresh must be added as there is occasion. When the spirits change to a dark tincture, which will sometimes happen, they should be poured off, and fresh put in their room; but with somewhat less acid than at first.

The glasses which contain the *preparations* should be of the finest sort, and pretty thick; for through such the parts may be seen very distinctly, and of a true colour, and the object will be so magnified as to shew vessels in the glass which out of it were not to be seen.

As the glass when filled with the liquor has a certain focus, it is necessary to keep the *preparation* at a proper distance from the sides of it, which is easily done by little sticks suitably placed; or by suspending it by a thread in a proper situation. The operator should be cautious of putting his fingers in this liquor oftener than is absolutely necessary; because it brings on a numbness on the skin, which makes the fingers unfit for any nice operation. The best remedy for this is to wash them in water mixed with a few drops of oil of tartar per deliquium. Med. Ess. Edinb. abr. Vol. II. p. 9.

Dr. Christ. Jac. Trew prefers the rectified spirit of grain for preserving anatomical *preparations* to spirit of wine, or compositions of alcohol, amber, camphor, &c. because these soon change into a brown colour; whereas the spirit from malt preserves its limpid appearance. When any part is to be preserved wet, wash it with water till it is no more tinctured. The water is next to be washed away with spirits, and then the *preparation* is to be put among spirits in a glass, the mouth of which is to be closely covered with a glass head, over which a wet bladder and leaf-tin are to be tied. Com. Lit. Norimb. 1731. Semest. 1. Specim. 9.

PREPARATION *of insects*, in anatomy. See INSECTS.

PRESA, in the Italian music, is in general a character which shews when and where a performer in a concert is to begin to sing

fing or play: but in particular, in fugues or canons it is thus marked + over the note at which the fecond part, which is to follow or imitate the firft, muft begin. If the mark be repeated a fecond time, it is to fhew the place where the third part muft begin, to imitate the fecond; and fo on through all the parts. See USUS.

PRESBYS, in zoology, a name ufed by many of the antient naturalifts for the *regulus criftatus*, or golden-crowned wren. *Ray's* Ornithol. p. 163. See REGULUS *criftatus*.

PRESERVATION *of Corn*. A fuccefsful method of *preferving corn*, for the ufe of armies, and againft times of fcarcity, is a moft ufeful and curious object of enquiry.

It is well known that accident often preferves *corn* very long, when all the care in the world fuffers it to decay in a few years, the owner knows not why. One very remarkable inftance we have recorded in the memoirs of the academy of fciences at Paris, in 1708, of fome *corn* laid up in the citadel of Metz, in the year 1578, which had kept good to that time without any particular care. It was on this occafion that the fubject of *preferving corn* in general became the employment of the thoughts of the members of the academy, and Mr. Reneaume obferved,

1. That *corn* can never be too dry when it is brought into the granary, if intended for long keeping; and that in order to keep, it muft be preferved quite dry and quite clean.

2. That tho' fome have imagined that *corn* increafes in fize in the granary, and therefore fhould be cut after a wet feafon, and in dewy mornings; yet on the contrary, *corn* never fwells, if well preferved, but always fhrinks and wrinkles up a little: and that the *corn* of dry feafons is always obferved to keep much better than that of wet ones, which ufually heats and decays. And that as to dewy mornings, they are never to be chofen for reaping, unlefs on particular occafions; as when the feafon has been fo remarkably dry, that the *corn* is loofe in the ears: then, indeed, there is danger of its being loft by falling out while the reaper cuts the ftalk, and this is prevented by cutting it while the dew has wetted the hufks, or the grains of *corn*, and retains them in their places.

4. It is very certain, that any *corn* which is dry will, on laying it in a moift place, fwell and increafe in bulk, and will become larger by this means. The merchants generally are able to find this out, however, and do not care to buy fuch *corn*, well knowing that it is very fubject to mould and decay. There is another yet more artful method than this in too common ufe among the petty merchants, who buy up *corn* to fell it to the larger dealers, which is this: they heat a large piece of freeftone, and inclofing it in an iron box, they thruft it under the heap of *corn*, and carefully remove it about to every part, at the fame time gently moiftening the *corn*; the effect of this is a very confiderable fwelling of the *corn*, infomuch that what they buy as fixteen bufhels, they fell after this for feventeen; but there is no wonder that *corn*, treated in this manner cannot keep. This is an artifice often practifed alfo on oats, and is more profitable in that, as the oats will gain at leaft twice as much in quantity by it as wheat or barley.

5. If it is abfolutely neceffary at any time to lay up *corn* in a place that is damp, it is beft to lay it up in the ear, not in the loofe ftate, fince in that cafe the ftalk and hufks will abforb a great quantity of the moifture, and preferve the *corn* in fome degree from it. The leaving the chaff with the *corn*; that is, the threfhing, but not fanning it, may alfo be of ufe in many cafes, and this takes up but little room in a magazine, and it is much the fame thing to the proprietor, whether it be all fanned together, or be only fanned in quantities fufficient for a certain number of days, as it is wanted to be ufed; but tho' the trouble is the fame, the advantage is not fo, but is greatly on the fide of the latter practice: we all well know the ufe of chaff, and the like dry fubftances in preferving fruits for the winter; and this might alone give a hint that *corn* might fare the better for it; but we have alfo this additional mark of its ufe in preferving *corn*, that the zea or fpelta, called fpelt *corn* and white *corn*, and ufed for food in many parts of Germany, is always preferved in the hufk, and is found the leaft fubject to decay of all *corns*.

From thefe confiderations it is eafy to learn, what are to be the principal objects of our care in the preferving *corn* for the ufe of armies, &c. The granary muft be a well chofen place; and according to Vitruvius's rules, fhould always be at the top of a houfe, and have its openings only to the north or eaft, that the *corn* may not be expofed to the damp winds from the fouth and weft, which are very deftructive to it; whereas the contrary ones are very neceffary and wholefome to it, ferving to cool and to dry it from all external humidity, from whatever caufe. There muft alfo be openings in the roof to be fet open in dry weather, partly to let in frefh air, and partly to let out the warm effluvia which are often emitted by the *corn*. The covering of the roofs fhould always be of tiles, becaufe in the worft feafons, when the other openings cannot be fafe, there will always be a confiderable inlet for frefh air, and a way out for the vapours by their joinings, which are never clofe. If there happen to be any windows to the fouth, great care muft be taken to fhut them up in moift weather, and in the time of the hot fouthern winds.

There muft never be a cellar, or any other damp place under a granary, nor fhould it ever be built over ftables; for in either of thefe cafes the *corn* will certainly fuffer by the vapours, and be made damp in one and ill-tafted in the other. Mem. Acad. Par. 1708.

The accidents that attend *corn* in public granaries, are of the utmoft importance, and ought to be well underftood and guarded againft. See GRANARY.

Dantzic is the grand ftorehoufe, or repofitory of all the fruitful kingdom of Poland. The wheat, barley, and rye, of a great part of the country are there laid up in parcels of twenty, thirty, or fixty lafts in a chamber, according to the fize of the room; and this they keep turning every day or two, to keep it fweet and fit for fhiping. A thunder ftorm has fometimes been of very terrible confequence to thefe ftores. All the *corn* of the growth of former years having been found fo much altered by one night's thunder, that tho' over night it was dry, fit for fhiping or keeping, and proper for ufes of any fort, yet in the morning it was found clammy and fticking. In this cafe there is no remedy, but the turning all fuch *corn* three or four times a day for two months or longer; in which time it will fometimes come to itfelf, tho' fometimes not.

This effect of thunder and lightning is only obferved to take place in fuch *corn* as is not a year old, or has not fweated thoroughly in the ftraw before it was threfhed out. The latter inconvenience is eafily prevented by a timely care; but as to the former, all that can be done is carefully to examine all ftores of the laft year's *corn* after every thunder ftorm, that if any of this have been fo affected, it may be cured in time; for a neglect of turning will certainly utterly deftroy it Phil. Tranf. N°. 96.

PRESERVATION *of other vegetables*. This is to be done feveral ways in the feveral kinds, and many more might certainly be invented; for we are not yet arrived at the perfect method of *preferving vegetables* with their colours, odours, and all their fenfible qualities, as well as their natural form for a number of years. Fruits may be long *preferved* in fpirit of wine, firft well faturated with the fkins and tinging parts of thofe fruits; and many may be tolerably *preferved* in perfectly fermented liquors, which generate no more air. The more folid *vegetable* fubftances may be *preferved* by gently drying in the fun fhade, or other flack heat. Thus peas or beans may be dried young in a flack oven in their proper feafon, and may afterwards be boiled in the winter, and will eat young and tender, as if juft gathered. The ways of *preferving* fruits both dry and moift, with fugar, are now univerfally known; and there are in the feveral ways many fecrets in the hands of particular artifts, which it would be well to have generally known. *Shaw's* Lectures, p. 196.

PRESS *(Cycl.)*—PRESS, in the manege. A horfe is faid to refift, or *prefs* upon the hand, when either through the ftiffnefs of his neck, or from an ardour to run too much a head, he ftretches his head againft the horfeman's hand, refufes the aid of the hand, and withftands the effects of the bridle.

If your horfe is too fiery, and *preffes* upon the hand, endeavour to pacify him, by making him go more foftly, and pulling him backwards; and if it proceeds from a ftiffnefs of the fhoulders and neck, you muft fupply him with a caveffon made after the Duke of Newcaftle's way. See HEAVY.

PRESS is alfo ufed for pufhing a horfe forewards, by affifting him with the calves of your legs, or even fpurring him, in order to make him go on.

PRESS, or PRESSING, in the fea language. See MANNING.

PRESTER, *(Cycl.)* a word ufed by fome to exprefs the external part of the neck, which is ufually inflated in anger: with others it is a name for the ferpent *dipfas*.

PRESTESSE, in the manege, is ufed to denote the readinefs and diligence of a horfe in working a manege.

PRESTISSIMO, in the Italian mufic, intimates to perform extremely quick, haftily, and with fury.

PRESTO, in the Italian mufic, is ufed to fignify that the part it is joined to fhould be performed gayly, faft and quick, yet not with rapidity.

Non tropo PRESTO, or *men* PRESTO, in the Italian mufic, fignifies not too quick, or lefs than *prefto*.

Piu PRESTO, in the Italian mufic, is ufed to intimate that we fhould fing, or play the part to which it is annexed, a little brifker and quicker than the *prefto* alone requires. When *piu* is added to other words, as *adagio*, *grave*, *vivace*, &c. it adds in like manner to the flownefs, or quicknefs of the movements, refpectively.

PRESTO, PRESTO, in the Italian mufic, the fame with *preftiffimo*. See PRESTISSIMO.

PRESUMPTION, *præfumptio*, in rhetoric, the fame with *prolepfis*. See PROLEPSIS.

PRETERNATURAL *rains*. See the article RAINS.

PRIAPE *de mer*, in natural hiftory, a name given by the French to a peculiar fpecies of canalis, or tubulus marinus, called alfo by fome authors of that nation, the *arrofoir*.

It is an oblong, and thick-fhell of this kind, with a large head, which is pierced thro' with a great number of holes, fo as at once to refemble, in fome fort, the glans of the penis, and the head of a common gardener's watering-pot. This fpecies is found at Amboina. See CANALIS.

PRIAPEIA, *(Cycl.)* in botany, a name given by John Bauhine and fome other authors, to the fmall fpecies of tobacco called by Mr. Tournefort and others, *nicotiana minor*. See the article NICOTIANA.

PRIAPOLITHUS, a name given by fome authors to a ftone found about Caftro in Italy, which very aptly refembles the figure of the human penis.

PRICK *(Cycl.)*—PRICK, or PINCH, in the manege, is to give a horfe a gentle touch of the fpur, without clapping them hard to him. To *prick* or *pinch*, is an aid; but to *appuyer*, or bear hard with the fpur, is correction.

PRICKING *(Cycl.)*—PRICKING *of a horfe's foot*, in the manege, is the hurt received by a nail driven too far into the foot, fo as to reach the quick, or prefs the vein in the horfe's foot when he is fhod.

PRICKLE *back*, in natural hiftory, a fmall fifh fo called from the *prickles* on its fides and back. Vaft numbers of thefe little fifh are to be found in almoft all frefh waters, wherever it is poffible for fifh to live, as Mr Arderon informs us, Phil. Tranf. Nº. 482. fect. 15. who gives us fome account of thefe creatures. They are very deftructive to the fpawn of all forts of fifh; and they themfelves are tormented to death by a kind of loufe of an oval figure, with eight legs and a very tranfparent body. This loufe has little fins always in motion, whether it be fwimming about or fixed on the fifh

PRIDE *of the Ifis*, a name given by Dr. Plot to the common lampern, from its being found very plentifully and very delicate in that river.

It is to be obferved, that we diftinguifh between the lampern and lamprey, which, tho' words very nearly the fame in found, are yet the names of two different fifhes: what we call the lampern, is the *lampetra parva fluviatilis* of Willughby; this is the fifh found in the Ifis. The lamprey is the *lampetra* of Willughby, and others: they are both fpecies of the petromyzon of Artedi. See the articles PETROMYZON and LAMPETRA.

PRIDE *gavel*, a cuftom in the manor of Rodely in the county of Gloucefter; by which to this day a rent is paid to the lord, by certain tenants. in duty and acknowledgement to him for their liberty and privilege of fifhing for lampreys or lamprids in the river Severn. *Tayl.* Hift. Gavelk. 112 *Blount.*

PRIMIER *(Cycl.)*—PRIMIER *ferjeant*, the King's firft ferjeant at law.

PRIMING *(Cycl.)*—PRIMING-*iron*, in gunnery, a fmall fharp iron, which is thruft into the touch-hole of a great gun, and pierces into the cartridge that holds the powder, that fo they may put in the *prime*-powder, or touch-powder, to fire off the piece.

PRIMO *(Cycl.)*—PRIMO, in the Italian mufic, is often abridged thus, Pº. or Iº. and added to other words, as, *primo canto*, the firft treble; *alto primo*, the firft counter tenor; *tenore primo*, the firft tenor; *baffo primo*, the firft bafs; *fagotto primo*, the firft baffoon; *choro primo*, the firft chorus, &c.

PRIMULA, *or* PRIMULA *veris*, in the Linnæan fyftem of botany, the name of a genus of plants, the characters of which are thefe: the cup is a general involucrum, fmall, compofed of many leaves, and containing feveral flowers. The feparate perianthium of every flower is tubular, and of a pentagonal figure, compofed of one leaf, divided into five fegments, placed erect, and remaining when the flower is fallen. The flower is compofed of only one leaf, in form of a cylindric tube, of the length of the cup, terminated by a fmall hemifphere neck. The margin is fpread open, and divided into five fegments, which are obtufe, inverted in the fhape of a heart at their ends, and have a rim round their edges. The ftamina are five very fhort filaments, fituated within the tube of the flower. The antheræ are erect, pointed, and converge toward one another at their ends. The germen of the piftillum is globofe. The ftyle is flender, and of the length of the cup, and the ftigma is globofe. The fruit is a cylindric capfule, nearly of the length of the cup, covered, containing only one cell, and fplitting open. Its top is dented into ten fegments. The feeds are numerous and round. The receptacle is of an oblong oval figure and free. *Linnæi* Genera Plant. p. 63.

The characters of this genus, according to Mr. Tournefort, are thefe: the flower confifts of only one leaf, which is expanded wide at the mouth, and divided into feveral fegments. The cup is tubular, and from it arifes a piftil, which is fixed like a nail into the hinder part of the flower, and afterwards becomes a fruit, or an oblong cafe, clofely furrounded by the cup, and containing fmall roundifh feeds, affixed to a placenta.

The fpecies of *primula*, enumerated by Mr. Tournefort, are thefe: 1. The fweet yellow-flowered fingle *primula*, commonly called the *cowflip*. 2. The taller fingle *primula*, with a paler flower. 3. The fcentlefs *primula*, which has no cup to the flowers. 4. The fcentlefs *primula*, with double flowers. 5. The fweet *primula*, with indented or diffected cups. 6. The *primula*, with a foliaceous head inftead of flowers. 7. The yellow, mountain, hairy *primula*. 8. The red-flowered *primula*. 9. The white-flowered *primula*. 10. The great fcarlet umbellated *primula*, with a foliaceous ftalk and foliaceous flower. 11. The leffer yellow umbellated *primula*, with a foliaceous ftalk and flower. 12. The garden umbellated yellow *primula*. 13. The garden white umbellated *primula*. 14. The garden red umbellated *primula*. 15. The ferrugineous umbellated garden *primula*. 16. The common wild manyflowered *primula*. 17. The double many-flowered fpring *primula*. 18. The fweet proliferous *primula*. 19. The largeflowered proliferous *primula*. 20. The white-flowered proliferous *primula*. 21. The purple-flowered proliferous *primula*. 22. The ferrugineous-flowered proliferous *primula*. 23. The great-flowered, pale, whitifh, fingle *primula*. 24. The pure white fingle-flowered *primula*. 25. The green-flowered fingle *primula*. 26. The double green-flowered *primula*. 27. The green and white fingle-flowered *primula*. 28. The doubleflowered feparately divided *primrofe*, called *Hefket's primrofe*. 29. The deep green-flowered *primula*, with fimbriated edges. 30. The Conftantinople *primula*, with a pale purple flower. 31. The Conftantinople *primula*, with a large purple flower. 32. The Conftantinople *primula*, with fmaller purple flowers. 33. The Conftantinople *primula*, with a fcarlet flower. 34. The Conftantinople *primula*, with a ferrugineous flower with white fpots. 35. The Conftantinople *primula*, with white flowers. 36. The Conftantinople *primula*, with pale flefhcoloured flowers. 37. The Conftantinople *primula*, with yellow flowers. 38. The Conftantinople *primula*, with pale lemon-coloured flowers. 39. The Conftantinople *primula*, with a rufty whitifh flower. 40. The Conftantinople *primula*, with a bruwnifh flower.

The flowers of this plant are efteemed greatly cephalic and nervine. They are recommended in palfies, apoplexies, and all nervous diforders.

The *primula* may be known when not in flower, by their having rugged and wrinkled leaves of a thin confiftence. *Tourn.* Inft. p. 124, 125.

PRIMUS *(Cycl.)*—PRIMUS *Brachii moventium*, in anatomy, a name given by Vefalius, and fome others who have copied from him, to a mufcle generally known under the name of the *pectoralis*. See the article PECTORALIS.

PRIMUS *communium laryngis*, in anatomy, a name given by Cafferius and fome others to the mufcle more generally known by the name of the *fternothyroidæus*, or *fterno-thyroides*. See the article STERNOTHYROIDÆUS.

PRIMUS *hyoidis offis mufculus*, in anatomy, a name given by Fallopius and fome others to the mufcle of the *os hyoides*, called by Albinus *fternohyoidæus*.

PRIMUS *oculum movens*, in anatomy, a name given by Vefalius to one of the four *mufculi recti* of the eye, called by Albinus and others the *adductor*. It is called by Fabricius the *rectus interior*, and by fome the *bibitorius*.

PRIMUS *propriorum auriculæ mufculus*, in anatomy, a name given by Cafferius to one of the mufcles of the head, called by Albinus the *auriculam attollens*, and by Cowper and Winflow *fuperior auriculæ*, which fee.

PRINCE *(Cycl.)*—PRINCE *of the Senate*. There was one member of the Roman Senate diftinguifhed always from the reft by the title of *Prince of the Senate*. This title was given of courfe to that perfon whofe name was called over the firft in the roll of the Senate, whenever it was renewed by the cenfors. He was always one of confular and cenforian dignity.

After the inftitution of the cenfors. it became a cuftom to confer this title of *Prince of the Senate* on the oldeft fenator then living of cenforian dignity. Yet there were no peculiar rights annexed to this title, nor any other advantage, except an acceffion of authority, from a notion which it would naturally imprint of a fuperior merit in thofe who bore it. *Middleton* of Rom. Sen. p. 147, 149. See SENATE.

PRINCE *of pleafantry, prince de plaifance*, in the cuftoms of Flanders. See SPORTS.

PRINCE *of the horfe-comb*, in the cuftoms of Flanders. See SPORTS.

PRINCES *feather*, in botany, a name given to the amaranth. See AMARANTH.

PRINCES *metal*. Copper, tho' one of the lefs precious *metals*, yet has been found of fo great ufe in the common affairs of life, that fcarce any other has been fubject to fo many trials for its improvement, or the rendering it either more beautiful or more fit for certain purpofes.

One of the firft difcoveries in thefe attempts was the making it into brafs, by means of an addition of lapis calaminaris; and tho' it was not at that time known to be a ftone which contained any *metal*, yet the brafs was always found to weigh one third more than the copper which had been ufed in the procefs.

This yellow metal gave many people hopes of making copper approach yet nearer to gold, and without knowing that zink was the feparated metalline part of lapis calaminaris, the experimenters foon found, by happy accident or repeated chance mixtures, that it would give copper a yet finer and purer yellow; but it was alfo found, that this mixed *metal* was much more brittle than brafs made in the common way. This, however, did not prevent the world from ftill valuing it for fuch works as were to be finifhed by cafting, and did not require the hammer: and we, who firft had it in perfection,

called it *princes metal*, from Prince Rupert, whom fome fuppofed to have been the inventor of it; but the greateft perfection this *metal* was ever brought to, was by two Frenchmen, Mr. La Croix and Mr. Le Blanc. Their methods of making the compofition, tho' both beautiful, were very different. Mr. Le Blanc's was the brighteft, and of the moft elegant and lively colour; but Mr. La Croix's was greatly fuperior to that in ductility and foftnefs, fo that it was very eafily malleable.

Mr. La Croix invented a fort of varnifh or lacquer for his *metal*, which added a fomewhat deeper tinge to it, as it was naturally rather too pale; and had this farther advantage, that while it remained on the *metal*, it preferved it from ruft or decay. This is a very material point in regard to a *metal* of which copper is the bafis, fince that is, of all other *metals*, moft fubject to be injured by the air, or by the contact of liquids of almoft any kind. Mr. Le Blanc's *metal* is of a deeper, yet equally lively colour, and remarkably bright; and is of fuch a temper as to be admirably fitted for working. The whole hiftory of thefe *metals* is certainly, that they are compofed of zink and copper in different proportions the one to the other; but it is not eafy, without the help of numerous experiments, to determine what is to be the true proportion for either.

The microfcope, however, fhews a manifeft difference, which may lead fomewhat towards it; for the *metal* of La Croix is feen to be compofed merely of a number of irregular ftriæ, while the other is difcovered to confift of always two regular beds of them, which meet in the center of the piece; hence it is that this is always brittle, and will not well polifh. The fabrick of thefe *metals* was long kept a fecret; but it was always to be difcovered by melting it in a crucible in a ftrong fire, when it always fent up plain flowers of zink, and the remaining *metal* appeared no other than copper altered by calamine; that is, common brafs. Mem. Acad. Par. 1732.

PRINCIPALIS, in fome antient Latin writers of mufic, is ufed for the chord or note called ὑπατη by the Greeks. See the articles HYPATE, TETRACHORD, and DIAGRAM.

PRINCIPIUM *recti abdominis*, in anatomy, a name given by Vefalius to a mufcle generally known at this time under the name of the *pyramidalis*.

PRINCIPLE (*Cycl.*)—Some antient philofophers diftinguifhed between *principles*, αρχαι, and elements στοιχεια. *Principles* according to them, were neither compofed nor produced; but the elements were complex or compounded beings. *Plutarch*, ap. Ellet. in Mem. de l'Acad. de Berlin, 1746.

It would be endlefs to enumerate all the opinions of philofophers concerning the elements of bodies. A late author has given us a fummary of many of thefe opinions; and, laftly, adds his own, that fire and water are the only things which properly deferve the name of elements, or *principles* of natural bodies; fire being the active, and water the paffive *principle*. According to him, water is convertible into air, and into earth, by means of fire. Hence the four, vulgarly called elements, may be reduced to two. He endeavours to eftablifh his doctrine on the experiments of Boyle, Hales, and Mufchenbroek. Vid. *Eller*, in Mem. de l'Acad. de Berlin, 1746.

Original PRINCIPLE, *principium originale*, a name given by Tachenius and fome other authors, to falt, without confidering it as acid, alkali, or of any other particular kind, or any mode of exiftence. The falt of wood or vegetables, not being alkali till after burning, and fo on; but falt that is the bafe of thefe, being evidently exiftent in the bodies, and, in regard to wood, feeming indeed to conftitute its character as fuch, fince the evaporation of it caufes the wood to loofe all its ftrength and to decay: for we find that in rotten wood there is no alkali at all; and the Venetians, who fink their timber for fhip-building into water while it is green, prevent, by that means, the evaporation of thofe falts, and leave the wood little lefs durable than ftone. On thefe and the like principles, Tachenius fuppofes falt to be the true *original principle* of bodies; but many others allow this name only to water, or at leaft that water is, in almoft all natural bodies, the moft copious, the moft active, and the moft influencing part; yet even this is found to agree much better with fome bodies than with others. The birch and elder feed more kindly on a thin uliginous moifture; the elm, the pine, the fir, and cedar, chufe a ftronger liquor; yet thefe and many more, the moft widely different that can be from one another, are often feen to draw their whole fuftenance and bulk, whether annual or perennial, from the fame piece of ground, impregnated fo far as is poffible to be judged of with the fame fort of juices, and from the ambient air and dews, when as yet by our beft diligence we cannot diftinguifh the liquors or falts approaching clofely to their feveral roots; and if we wholly take away, and exchange all the earth from the roots of trees whofe barks, fap, and fruit, have very much differ ing falts, and are of very different kinds, yet we fhall find each tree to profper better by the exchange, inftead of being injured by it.

Hence we may fufpect, that the very contextures of the bodies of plants, from the firft germination of the feed, and as they form gradually from the invifible *principles* of their feeds, are, however fmall and imperceptible, the natural alembics, where the common water and air are changed into the different juices, gums, refins, &c. as the animal organization in the body of the cow changes the juices of every fort of grafs and efculent vegetable, into one and the fame milk. The fea-plants growing on fhells, or affixed to yet harder ftones, taking no nourifhment from the thing they grow on, but being as it were all root, and taking the whole from the ambient water; yet that water giving to different fpecies of them, tho' itfelf the fame to all, the different textures of herbaceous to fome; tough and horny to others; and to fome, abfolutely ftony; as to the corals, many of which have been efteemed by the generality of authors, abfolute ftones.

Trees of feveral different kinds are found in America growing out of the fame dry and hard rock, and the various kinds of fucculent plants; the poifonous ones and their oppofites, or remedies, as the euphorbium and the antieuphorbium; the moft acrid and pungent, and the moft foft and emollient, out of the fame barren lands of Arabia, where it could not be expected that any plant could grow at all. Hence it is eafy to apprehend, how the feeds in their time, and after them the roots, ftems, and leaves of trees, may be the proper ftrainers to feparate and prepare the feveral faps and juices, and to ferment the liquors into their feveral particular falts. See the article VEGETATION and SALT.

PRINCIPLE, in chemiftry. It is impoffible to difcover the virtues of any body, or to find how mixed bodies of different kinds ftand related to the human body, either for the prefervation of its functions entire, or the reftoring them when loft or impaired; or, finally, for the total deftruction thereof; till we know the *principles* of which they confift, and likewife the mixture and proportion of fuch *principles* in bodies to which their effects are chiefly owing. Wherefore having difcovered by various ways the parts into which a true chemical analyfis refolves bodies, we muft look upon fuch fimple parts into which all mixts are refolvable, and of which they feem to be compounded, as their true and genuine *principles*.

The antient chemifts having obferved, that in analyfing all bodies whatever, they obtained a fpirit, or mercury, fulphur, falt, water, and earth, concluded the number of *principles* to be five. If wine, for inftance, be diftilled in a proper alembic, a burning water or fpirit will firft arife, and next an infipid water, which they call phlegm; a thick vifcid mafs alone remaining in the ftill; this put into another veffel, or retort, and expofed to a more intenfe and violent heat, a fmall portion of phlegm comes over firft, then an acid water, which according to them is ftill fpirit or mercury, and next a fat oily fubftance, called fulphur: what remains ftill in the retort is next burnt to afhes in an open fire; thefe afhes are thrown into an earthen veffel, with a proper quantity of boiling water, which they impregnate with their falt; this water being filtred thro' cap paper, and afterwards evaporated, leaves the falt at the bottom of the veffel; and the other part of the afhes, which the water could not take up, or have any effect on, is termed the earth of the fubftance, or its caput mortuum.

Of thefe five *principles* the chemifts have reckoned two to be paffive, water and earth; and three to be active, fpirit, fulphur, and falt; and on thefe laft they have thought the whole virtue of the mixed body depended. In this analyfis we may obferve, that there is a twofold fpirit; one oily and inflammable, which rifes firft by a gentle heat, and is termed fpirit of wine, another acid penetrating like that of vinegar. Befide thefe, the chemifts give the name of fpirit to other penetrating volatile, or urinous liquors, obtained from the parts of animals; fuch as the fpirit of urine, hartfhorn, and fuch like fubftances: but the later chemifts have banifhed thefe fpirits from the number of their *principles*, as being nothing elfe than fulphur and falt diffolved in water. Thus fpirit of nitre, and others of that kind, are only acid falts in water; fpirit of hartfhorn, or urine, alkaline falts; and fpirit of wine, or of turpentine, an æthereal attenuated oil.

Some of the moderns deny likewife, that either fulphur or falt deferve the names of *principles* or elements, as not being the moft fimple fubftances producible by chemiftry. For fulphur, when heated with due care, may be refolved into falt, water, and earth; as is evident by diftilling fetid diftilled oils feveral times with quick-lime, which by this treatment yield in large quantities a volatile falt, diffolved in phlegm, together with a caput mortuum or earth. Æthereal oils alfo are only fat thick oils, like that of olives, attenuated by falts and diffolved in water; as may be proved by thefe two experiments. If oil of olives, or any other of that kind be mixed with a fermenting liquor, fuch as a folution of honey in water; the whole may be converted into an inflammable fpirit. And if a quart of fpirit of wine, diluted with fix quarts of common water, be expofed in a cold place to the open air, the volatile falts will fly off and leave drops of oil fwimming at top, which are in every refpect the fame with oil of olives or almonds.

Salt is no more a *principle* than fulphur; becaufe it may, by proper management, be at length reduced to earth and water.

Thus nitre by distillation may be almost wholly reduced to an acid spirit; but if it be burnt with tartar, or charcoal dust, it becomes an alkali salt, called fixed nitre: this, if suffered to run per deliquium, and afterwards filtred thro' cap paper, will leave a large quantity of earth behind; and if the same liquor be distilled to dryness, an insipid water will come over, and the salt remaining at the bottom of the retort, will be found to have lost a great part of its quantity; and if the operation be often repeated, nothing will at length remain but earth. Again, the vitrification of alkaline salts seems to be nothing but the conversion of them into earth; for glass has no qualities different from those of earth.

What we have proved by experiments, in resolving bodies, may be farther confirmed by others relating to the formation and composition of them; and particularly by Van Helmont's famous experiment of the willow. He took about two hundred pounds of earth dried in an oven, and put it into a vessel covered with an iron-lid full of holes: in this earth he set a branch of willow, weighing about five pounds; which soon took root, and grew so much, that in eight years time it weighed one hundred and sixty pounds; the earth it stood in having, during all this time, lost only a few ounces; so that the whole increase of the tree must have been owing to rain water, with a very small proportion of earth; and the salts and sulphurs therein must have been composed of two elements alone. The experiments of this kind, made by the illustrious Mr. Boyle on small sprigs of mint, marjoram, balm, pennyroyal, &c. set in small vials filled only with pure water, are yet more to be depended on. These increase in a short time to double their first weight; and being afterwards distilled, they yielded the very same principles they would have done, had they grown in the most proper soil. From all this it cannot but be allowed, that salt and oil owe their original to water and earth.

Water and earth do indeed, in the strictest sense, deserve the name of *principles*; but in the formation of mixed bodies a third *principle* must necessarily concur with them; for as they are of themselves wholly unactive, something must be supposed to give them their motion and activity: without this, water would immediately turn to ice; and as there are few bodies out of which fire may not be drawn, it is evdient that there must be some active, moveable *principle* in them all, to which the motion of the other parts is owing. Therefore, tho' this *principle* should not fall under our senses in the same manner as the others do, that can be no reason for doubting its existence, since it must concur in the composition of all bodies; which, if they were made of water and earth alone, would remain for ever without any virtue or energy. This they must receive from another *principle*; and according to the different combinations of all the three, bodies are formed with different properties and powers. We acknowledge, therefore, three simple substances in bodies, which are properly elements or *principles*; one active, which may be termed fire; and two passive, water and earth. From the most simple union, or connection of these three, salt arises; which consequently is to be looked upon as the most simple of all mixed bodies. The next to that in simplicity is sulphur or oil, made by an union of these three *principles*, and of salt. *Geoffroy*, Tract. p. 5.

Elementary earth is the same with the *terra damnata*, or *caput mortuum* of the chemists; being a simple, friable, porous substance, without smell or taste, consisting of particles of no regular figure, and altogether unfit for motion. The porosity of earth seems to arise from the irregular figure of its particles; and as these particles oftentimes touch one another only by their angles, the whole mass must necessarily be friable, and the want of taste and smell may be owing to the inaptitude of the particles of earth to motion.

In any analysis of bodies, the last thing is always this *principle* earth; and in their composition it seems to serve as a basis or foundation to the other parts of the mixture, and to it the dryness, solidity, and hardness of bodies is in a great measure to be ascribed. *Geoffroy*, Tract. p. 11.

Elementary water is a simple liquid, insipid, inodorous, pellucid substance: its fluidity is owing entirely to the action of fire, and when that action is very great, its parts are actually divided, and the whole turned to vapours; but when it is very small, they cohere strongly, and turn to ice. This element some chemists call *phlegm*, and it may be conceived to consist of small smooth particles, of an oblong or oval figure, and perfectly rigid and inflexible. From the minuteness of its particles it easily penetrates the pores of almost all bodies. An oval figure seems more agreeable to the fluidity of waters, as also to its motion, than a sperical one; and likewise to the solidity we observe in ice, the points of contact in spherical bodies being too few to form so strong a cohesion. Were its particles angular and flexible, they would be too weak to penetrate and dissolve salts, and would likewise be too much resisted; but as their surface is smooth, they can easily enter the substance of salts, and afterwards as easily separate their parts, that is, dissolve them by their rigidity and oval figure. The want of taste and smell in water seems to be owing to the smoothness, obtuseness, and smallness of its particles, which cannot vellicate the nerves of the tongue and nostrils. The fluidity of the water arises from the smallness, smoothness and figure of its particles, and from their easy motion by the fire contained in their interstices. Without the action of fire separating these particles, and keeping them in continual motion, their fluidity would presently be lost, how much soever their natural figure may dispose them to it, and they would become one solid mass. On the other hand, if the action of fire upon them be very great, they are farther separated from one another, and fly off in vapour and smoke. In fine, water is transparent, because its pores are so disposed, as readily to transmit the rays of light. *Geoff.* Tract. p. 10.

We reckon elementary fire the first *principle* of bodies, as being that from whence all the rest receive their activity: it is a simple and most subtle body, in a continual swift motion, filling and easily penetrating the pores of all other bodies. Its immense subtlety is evident from this, that it pervades all bodies whatsoever, and its swift motion from that rapidity which it is capable of communicating to them. Its force is in proportion to the quantity of it any where collected. In the sun, which may be looked upon as a vast congeries of this substance, its motion is most violent. In culinary fires, the quantity and motion of it are not so great, but still greater than in spirituous and volatile liquors, where it is hardly to be perceived, except when they are set on fire. Not only all motion, but also heat is owing to fire, which as it exists in bodies, is nothing else but the excessive motion of their parts. It is too subtle and active ever to be collected pure in chemical analyses; wherever it is found it is always united with water and earth in salts and sulphurs; and is sometimes concentred in bodies in so great quantities, as considerably to increase their weight; as is evident in calcined antimony, in which there is in the operation an addition made of almost a fifth part. *Geoffroy*, Tract. p. 9.

What the chemists call oil or sulphur, is not a simple substance, but a body compounded of earth, fire, water, and salt; but as it is usually separated entire in chemical analyses, it has been usually esteemed a chemical *principle* or element of bodies; and is, indeed, tho' a real compound, yet not without considerable difficulty to be reduced to its *principles*. It may be defined to be a fluid, viscid, inflammable, transparent body, without taste or smell, (tho' by mixing it differently with salts these different qualities are produced) compounded of fire, water, earth, and salt; and it may be conceived to consist of many flakes, or flocculi, each of which is again made up of very small flexible filaments, formed of the four *principles* before mentioned, by fermentations, as well in the bowels of the earth, as in the bodies of vegetables and animals; thus an aromatic plant growing in water will, by distillation, yield an oil, which could never have been obtained from the water in which it stood; and all oils may by art be resolved into water, earth, and salt: from these filaments variously concreted arise the flakes already mentioned, which are of different thicknesses; and in the pores thereof is lodged the element of fire, which also runs in little streams thro' their interstices. On these depend the specific levity, inflammability, and fluidity of oil; but as notwithstanding the intestine motion caused by the element of fire, the flocculi still adhere, in some measure, together; this fluid must necessarily be more viscid than any other.

From what has been said concerning the nature of alkaline salts, and the figure and structure of the oily flocculi, it is easy to conceive why all alkalies dissolve sulphurs; for since the alkaline particles are spherical and prickly, they cannot enter the interstices of these flocculi, without carrying away some of them from the rest, and thus by degrees thoroughly dissolving them. But the dense, rigid, and pointed moleculæ of acids being laid into these interstices, increase the density, and strengthen the texture of the flocculi; and from the diversity of these and of the acid spicula mixed with them, arise the different kinds of sulphurs.

Sulphurs formed in the earth, of fire, acid salt, water, and a very fine earth, are termed simple bitumens, and these bitumens dissolved in a large quantity of water, form the mineral oils or petrolea; but if they are mixed with earth and salt, the common solid bitumens are produced, differing from one another in degrees of purity, according to the quantity and grossness of the earth, or different degrees of mixture. Thus fossile or pit-coal, jet, amber, and the common bitumens, and bituminose earths are produced. If there be but a small quantity of earth and much acid salt, the common mineral sulphur or brimstone is formed: if the mineral original bitumen is joined to a fusible earth, capable of vitrification, it communicates to it a metallic form, that is the sound, brightness, softness, ductility, malleability, and all the other sensible qualities of metals.

This origin of mineral bitumens may be confirmed by many experiments. If a mixture of equal parts of oil of vitriol, and oil of turpentine, be digested together for a considerable time in a very gentle heat, and afterwards distilled in a retort, there will come over first a yellowish liquor resembling petroleum both in smell and consistence; and what remains in the retort is at first a soft bitumen, and afterwards turns into a hard black mass, easily inflammable, and smelling in the burning exactly like fossile coal. But if the distillation be continued, a white acid liquor will next be obtained, which by

by ſtanding lets fall a grey powder, which is true common brimſtone; a yellow ſubſtance of the like nature adhering likewiſe to the neck of the retort; what is left behind being a black, ſhining, light, ſubſtance, diſpoſed in thin diſgregated ſtrata or plates, like ſome of the foliaceous talcs, and in theſe iron may be diſcovered by the help of the loadſtone. Thus therefore all theſe bitumens may be artificially produced; and the moſt accurate analyſes of the natural ones, confirm the manner of their formation

Thus the chemiſts have ſhewn, that metals are nothing but bituminous ſubſtances, which have undergone a long digeſtion; for by depriving them of their ſulphur they are firſt reduced to aſhes, and afterwards to glaſs; this is eaſily ſeen in the imperfect metals; for if any of them be expoſed to a long heat, and eſpecially if to the rays of the ſun collected by a large burning glaſs, the ſulphureous *principle* flies off, and only a calx or aſhes will be left behind; which in a more vehement degree of fire are preſently vitrified, and by reſtoring the ſulphur this glaſs may be again reduced to metal.

The inflammable ſubſtances in animals and vegetables, conſiſt of a different combination of the *principle* of ſulphur and acid ſalt; for the oil or ſulphur in theſe is formed by a ſmall portion of earth joined to the elementary fire, water, and acid ſalt; this oil when joined to an acid ſalt produces gums; when joined to a fine acid, and a new acceſſion of fiery particles, it produces eſſential oils and inflammable ſpirits; but if the acids are more groſs, by reaſon of a larger quantity of earth joined to them, it forms reſins, as we learn from the artificial compoſitions of all theſe ſubſtances. By mixing ſpirit of wine with volatile ſpirit of urine, we obtain a mucilaginous concretion, or thin gum: oil of olives and ſalt of tartar melted together, make a kind of ſoap or thick gum; and if ſpirit of wine be digeſted for a long time with oil of vitriol, and then diſtilled, an inflammable oil is obtained, reſembling in ſmell and other qualities the eſſential oils of plants, a true reſin being left behind in the retort.

In animals this ſame oleaginous *principle* forms the fat and other glutinous or gelatinous ſubſtances; theſe laſt being compoſed of an acid volatile ſalt and oil, as appears from their analyſis: but fat is made of the ſame oil and acid ſalt; for, if oil of olives and ſpirit of nitre be mixed together, and digeſted, a ſubſtance will be formed in all particulars reſembling the fat of animals.

Sulphureous ſubſtances found in bodies are either fixed or volatile. The fixed ſulphurs are either ſolid, ſuch as, fat, reſin, and the bitumens; or fluid, as oils Volatile ſulphurs are ſuch as fly off with a ſmall degree of fire, and have an appearance compounded of that of oil and water Such are inflammable ſpirits obtained from the fruits and flowers of plants. *Geoff.* Tract. p 17.

Tho' ſalt be in reality a mixed body, yet in the common analyſis of bodies it is obtained intire, and has therefore paſſed with many for a true chemical *principle*: a great deal of pains is neceſſary to decompoſe and reduce it to its natural *principles*, but with accuracy and caution it is reduced to water and earth. It is the ſole origin of taſte, ſmell, and many other of the moſt obvious properties of bodies, and may properly be defined to be a mixed body, formed by the concretion of fire, water, and earth, into a ſolid, rigid, ſubſtance, ſoluble in water, and fuſible by fire. As its particles may be conceived to cohere by large ſurfaces only, ſalt cannot be friable, like earth; but requires a conſiderable force to ſeparate its parts, which fly off from one another with a ſenſible noiſe like thoſe of glaſs. It becomes the cauſe of taſte and ſmell, becauſe its particles terminate in ſtrong points, which vellicate the nervous membranes of the tongue and noſe.

Salt is properly of three diſtinct kinds, acid, acrid or alkaline, and neutral, or ſal ſalſus, compounded of the other two. *Geoff.* Tract. p. 12.

Acid ſalt is a congeries of inflexible ſolid parts, of an oblong figure, pointed at both ends. That its particles are rigid and hard, appears from the force with which it divides and diſſolves ſolid bodies; and their ſharpneſs and pungency are evident from the effect they have on the tongue, different from the corroſion of the acrid or alkaline ſalts. Acid ſalt is eaſily diſſolved by water; and after this ſolution, its parts are equally diſperſed through that fluid, and have the ſame motion with it. Hence it appears, that the particles of both theſe ſubſtances have nearly the ſame ſpecific gravity; and likewiſe, that the motion of the aqueous parts is great enough to overcome the cohеſion of the parts of the ſalt.

Concerning the manner in which the particles of acid ſalt are compounded of fire, water, and earth, nothing can with certainty be determined. It may be conjectured, however, that ſeveral particles of water being collected into one little maſs, are cemented together by ſome particles of fire and earth, lodged in the interſtices left between them; and that all theſe taken together are diſpoſed in one oval form, or that of two cones joined by their baſes. This configuration, however, is not the ſame in all acid ſalts; but the differences may all be reduced to three, the nitrous acid, the muriatic, and the vitriolic. *Geoff.* Tract. p. 13.

Salt alkali has its name from the Arabian *kali*, a plant, from whoſe aſhes a ſalt proper for glaſs-making was obtained; and from thence it came to be uſed for the fixed ſalts got from the aſhes of all plants, and afterwards for all ſalts and other ſubſtances whatever, that will ferment with acids.

Acrid or alkaline ſalt ſeems to be a congeries of ſpherical particles, with rough, prickly ſurfaces; becauſe of their great diſpoſition to motion, and their corroſive burning taſte. The points of their ſurfaces act on the nervous papillæ of the tongue like ſo many files; whereas acid ſalt is only pungent. But then by theſe points a larger ſurface is expoſed to the action of the fire than could otherwiſe be, and thus the particles of ſome alkaline ſalts are very volatile, or eaſily raiſed by a gentle heat. The origin of this ſalt is probably from a connection of acid points and terreſtrial particles; becauſe, in many operations in chemiſtry, ſuch ſalts ariſe from the mixture of acid ſalts and earth; as we ſee particularly in the preparation of fixed nitre and fermentation of urine.

Nitre being diſtilled, leaves a compound fixed ſalt behind, of the ſame nature with ſea-ſalt; out of which, by a nicer diſtillation, an acid liquor may be extracted without any volatile ſalt, or at leaſt but a very ſmall quantity: but if the ſame fixed ſalt be previouſly fermented, and then diſtilled, it yields a large quantity of volatile ſalt, and a very little fixed ſalt or acid; becauſe by fermentation or calcination, the acid and terreſtrial particles are intimately mixed, the acid ſpicula entering the pores of the earth, and ſo forming new molecules, which are denſe and cloſe toward the center, and prickly on the ſurface by the acid points ſticking out. Such are the particles of volatile alkalies, of which, if a great number be joined together, they muſt cohere very ſtrongly by means of their points, and form maleculæ of irregular figures; in the pores of which, watery, ſulphureous, earthy, or acid particles may be received and abſorbed.

Hence it is, that theſe ſalts are ſeldom pure; and as they are very often filled with particles of earth, they reſiſt the moſt violent degree of fire, and will ſooner melt than be raiſed by it. This is the true nature of fixed alkaline ſalt, ſuch as ſalt of tartar, or the ſalts got from the aſhes of plants, called lixivial ſalts. If they be impregnated with ſulphureous particles, they continue very volatile, and are raiſed by a ſmall degree of fire; as we ſee in ſalt of urine, hartſhorn, and others got from animals.

Acrid ſalts eaſily melt, when expoſed to a moiſt air, becauſe the particles of water contained in ſuch air readily enter their pores: when thus melted, they become properly lixivia, and are commonly termed oils, as oil of tartar per deliquium. Volatile alkaline ſalts, diluted with water, are called volatile urinous ſpirits; ſuch as the volatile ſpirit of urine, of hartſhorn, of blood, and others. *Geoff* Tract. p. 14.

Neutral ſalt is a kind of ſalt compounded of acid and alkaline moleculæ united together, and the figure of its particles is chiefly owing to the kind of acid that enters its compoſition. The impreſſion theſe particles make on the tongue is more dull and languid than that made by acid or acrid particles alone; becauſe the moleculæ formed by the union of theſe are larger in bulk, and conſequently leſs diſpoſed for motion; and therefore, tho' there is a greater quantity of aculei, or points, in one of theſe moleculæ than in one of the former; yet their bulk make them leſs capable of entering the pores of the ſkin, and vellicating the nervous papillæ, than when they are in a disjoined ſtate. The taſte of theſe ſalts is termed ſaline, and varies according to the differences both of the acid and alkaline particles that compoſe them, according to the thickneſs of the ſpicula, their number, and the other parts that may be mixed with them. That this is the true original of this kind of ſalts, is evident from the artificial compoſition of ſuch a ſalt from acid and acrid particles blended together, and from the reſolution of them into the ſame. Thus by pouring ſpirit of nitre, of ſea-ſalt, or of vitriol, on ſalt of tartar, new ſalts are produced exactly of the ſame appearance with nitre, ſea-ſalt, and vitriol; and by analyſing theſe three ſalts, the eſſential ſalts of plants, ſal armoniac, and others of the neutral ſalts, an acid and an alkaline ſalt may be obtained, in ſome fixed, in others volatile. *Geoff.* Tract. p. 15.

PRINOS, in botany, the name of a genus of plants, the characters of which are theſe: the perianthium is very ſmall and permanent; it is compoſed of one leaf, lightly divided into ſix ſegments The flower conſiſts of one petal, and is of the rotated kind; it has no tube, but its edge is divided into ſix oval ſegments. The ſtamina are ſix erect tubulated filaments, ſhorter than the flower. The antheræ are oblong and obtuſe. The germen of the piſtil is oval, and terminates in a ſtyle, which is ſhorter than the ſtamina. The ſtigma is obtuſe. The fruit is a roundiſh berry, containing ſix cells, and is much larger than the cup. The ſeeds are ſingle; they are very hard and obtuſe, convex on one ſide, and angular on the other. In ſome ſpecies the ſtamina are but five inſtead of ſix. *Linnæi* Gen. Pl p. 151. *Plukenet*, p 452. *Gronov.*

PRINTING (*Cycl.*)—The arts and ſciences, eſpecially ſtatuary and ſculpture, were arrived at ſo great perfection among the Romans, at the time when that empire was in its greateſt glory,

glory, that it is much to be wondered at that the art of *printing* was not found out among them; an art so nearly allied to that of the cutting seals and the dies of medals.

The making these dies, and the stamping their coins with them, was, in reality, no other than *printing* on metal; and their impressing their seals, cut in cornelians, agates, &c. on wax, was another species of *printing* on this substance. And finally, a third sort of *printing* among them, was the impressing the name of the workman on their pieces of fine earthenware.

Mountfaucon, in his antiquities, gives the figures and descriptions of several very large sigilla of the Romans, in which the names were all cut in hollow, in capital letters; and he imagines, that the use of these was to mark large earthen vessels with, while the clay was soft, and particularly those large vessels in which the Romans kept their wines. It does not seem that this diligent enquirer into antiquity ever met with any of these sigilla with the letters or characters in relief, or standing out in the manner of our modern types for *printing*, since he mentions none such; yet the remains of the Roman antiquities in terra cocta, or earthen-ware, shew that they had some such, tho' they were less common than the others; these vessels sometimes being marked with letters going in, tho' in general they have them all standing out, as must be the case when the impression was given from a sigillum cut in creux.

There is now, in the collection of the Duke of Richmond, a sigillum of the other more rare kind, which brings the discovery very near to that of *printing*: on this all the letters are raised, as is also the verge or rim of the seal, in the manner of our types used this day in *printing*. The stamp is made of true antient brass, and has on it the common green coat of ærugo which distinguishes the true antique medals. The plate is near two inches long, and near an inch in breadth, and has on the back part a ring for the convenience of holding it for making the impression. The letters stand in two rows; they are the common Roman capitals, very well made, and their faces all stand exactly on the level with one another, and with the surface of the verge of the seal. This seal was exactly of the nature of our method of *printing* so many letters at once. It contains the name of one Caius Julius Cæcilius Hermias, some private man, as we have no account of any person of this name upon record. It served him probably to set his name to any thing, to save him the trouble of writing; and the name being that of some private man seems also to prove, that these sigilla were very common among that people. It was evidently made to be used on parchment, or some other such thin substance; and the manner of using it must have been by first dipping it into ink, or some other coloured matter, not plunging it so far as to touch the ground, so that the letters only became marked, and gave their figures on the paper. The ground of this seal is very rough and uneven, and thence also it is plain, that the use of it was not to press down any soft substance, such as clay, or the like; because the imperfection of the ground would, in that case, have been seen, whereas in the use it was really intended for, the ground never gave any impression, and therefore there was no reason for bestowing any pains in the working it even.

The first use of *printing* among the later ages, was by wooden blocks in this very manner; and it was not till long after this invention, that we learned the way of using separate types for the letters; and these were then called *typi mobiles*, in opposition to the blocks, where the whole page was contained together, which were called *typi fixi*. This signet of the Duke of Richmond's, which was found near Rome, is truly and properly one of those *typi fixi*, and prints off its impression on paper with our modern printer's ink, as well as any set of letters cut in this manner can be expected to perform. This seems, therefore, the most antient sample of *printing* that we know of; for, by the appearance of the metal, it seems to be of the higher empire.

It is plain, by this stamp, that the very essence of *printing* was known to the Romans; for they had nothing to do, but to have made a stamp with lines three or four times as long, and containing twenty lines instead of two, to have formed a frame of types that would have *printed* a whole page as well as Coster's wooden blocks, used in *printing* the book called *speculum salutis*, which was the first book *printed*, in the year 1440, and consisted of pictures of stories out of the bible, with some of the verses underneath each page; being *printed* from a block of wood, like a wooden cut. This was the first essay of the fixed types, from which the moveable, or common separate types were soon deduced; and it seems strange, that the Romans, who were as sagacious a people as any in the world, should not as easily have fallen upon the use of separate types, in which the whole art of modern *printing* consists, from such signets as these, as the later ages from Coster's wooden blocks, which were plainly no other than larger works of the same kind.

Cicero, in his book *de natura deorum*, has a passage from which Toland supposes that the moderns took the hint of *printing*. That author orders the types to be made of metal, and calls them *formæ literarum*, the very words used by the first *printers* to express them. It is plain from Virgil, that brands, with the letters of the owner's name, were in use in his time for the marking of cattle. And we have an account of the same artifice that is now used for the painting of cards being used by the emperor Justin, who could not write. There was a smooth board, with holes cut through it, in form of the letters of his name; and when he had occasion to sign any thing, this was laid on the paper, and he marked the letters with a pen or stylus dipped in red ink and directed through the holes. Philos. Trans. N°. 479, p. 393.

PRINTS. To take off printed cuts, so that the outlines and principal strokes may be exactly copied for graving, may be thus performed: if the *print* be not above a year or two old, the paper need only be moistened with water in the manner usually practised for *printing* cuts; but if it be more antient, it should be laid to soak all night in water, and afterwards hung in the air till it becomes dry enough for the press. The paper thus prepared, is to be laid with its *printed* side next the plate, thinly cased over with white wax, which is thus to be committed to the rolling press, whereby an impression of the cut will be obtained. *Boyle's* Works abr. Vol. I. p. 136.

PRIORITES, in botany, a name given by the antient Greeks to a plant which they recommend in medicine; but they do not clearly explain what it was. It is the same with the cestrum and psuchrotrophon of the same writers; and they say it was called *betonica*, *serratula*, or *rosmarinus*, by the Romans. It is evident, from a strict enquiry into their accounts, that the serratula was the plant they meant; for Pliny says, that the betonica was only a Gaulish name for this plant, and the place of growth, which is described to be wet shady places, evidently excludes what we call *rosemary* from any title to the name.

Apuleius has greatly perplexed the cause by saying, that the *priorites*, or betony, has leaves like the docks; but he does not distinguish between the betonica and britannica, which last plant is the hydrolapathum, or great water dock, and has leaves like the other docks; and it is plain, that both Apuleius and Pliny borrow the account of the dock-like leaves from this passage, and attribute them to a plant the original author never meant them for.

PRISMATIC *antennæ*, in natural history, a term used to express the horns or *antennæ* of a peculiar genus of butterflies. As those of the common kind are slender and buttoned at the end, these become very thick a little way from their origin, and continue of that diameter through their whole length, till just at the extremity they turn a little and terminate in a sharp point. The anterior part of these is rounded, as in the other kinds; but behind they are made up of two planes meeting in an angle, and each of these has a row of hairs on it: these meeting at their summits, form an angular vacant space or alley below *Reaumur's* Hist. Inf. See FEELERS.

PRISON (*Cycl.*)—*Breaking of prison*, by the law of Scotland, is a punishable offence; but there are no particular laws against it in that country, so they are guided by the Roman laws in such cases. But tho' this law seems to make the punishment of this crime capital, yet this is thought too great severity in Scotland, where an arbitrary punishment, greater or less, according to the circumstances of the escape, and the violence with which it was accomplished, is thought sufficient and adequate. *Math.* de Crimin. Carpz. Part 3. *Bayne's* Crim. Law.

PRISTIS, the *saw-fish*, a fish of very large size, and armed with a very remarkable weapon like a saw, at his nose, from whence he has his name See Tab. of Fishes, N° 5.

This fish, from its large size, is generally reckoned a kind of whale, but erroneously; for it is truly of the same genus with the galei or hound-fishes It is ash-coloured on the back, and white on the belly; its head is of a heart-like shape, and flatted; its mouth is placed far below the end of the snout, and in the under part of the head, as in the zygæna; its lips are rough and sharp, like a file, but it has no other teeth; its head is terminated by a long and flat, bony substance, furnished on each side with jaggs or points like deep teeth of a saw. There are from twenty to thirty of these teeth on each side. The body is round, and grows small towards the tail. The sword of this fish is sometimes five feet long. It is found in the western ocean.

PRIVET, *ligustrum*, in botany. See LIGUSTRUM.

The leaves and flowers of *privet* are cooling, drying, and astringent, and consequently good in ulcers and inflammations of the throat and mouth, bleeding of the gums, and relaxation of the uvula.

PRIVET-*fly*, in natural history, the name of a species of *fly* very common on the shrub from whence it has its name. It is called the *erinopterus*, and is remarkable for having its wings deeply divided into segments, so that they seem composed of feathers like bird's wings. The creature as it sits looks like a small feather.

PRIZES (*Cycl.*)—The officers and seamen of the king's ships, and of other British ships having letters of marque, are intitled to the sole interest, and property of all ships and goods by them taken, and adjudged lawful *prizes* by the court of admiralty. Stat. 13 Geo. II. c. 4. sect. 1 and 2.

The *prize* is to be divided among the officers and seamen of the

the king's ſhips, as he ſhall appoint by proclamation. Among privateers, the diviſion is according to the agreement between the owners. *Ibid.*

The court of admiralty are to finiſh the examination of the perſons to be examined to prove the lawfulneſs of the *prize*, in five days after requeſt for that purpoſe made. The monition is to be executed in three days. And in caſe no claim of the capture be duly entered, giving twenty days notice after the execution of the monition; or if there be a claim, and the claimant does not give ſufficient ſecurity to pay double coſts to the captors, if the *prize* be adjudged lawful, then the court are to proceed to ſentence in ten days. *Ibid.* ſect. 3.

In caſe of doubt, or of witneſſes being remote, the court may releaſe the *prize*, on the claimant's giving good ſecurity to the captors for the payment of the full appraiſed value, in caſe the *prize* be adjudged lawful. *Ib.* ſect. 3. fin.

Judges and officers, on failure of their duty, in reſpect to the condemnation of *prizes*, forfeit 500 l. with full coſts of ſuit; one moiety to the king, and the other to the informer. *Ib.* ſect. 6.

The judges and officers of the court of admiralty in the king's plantations or dominions abroad, ſhall not receive above 10 l. in caſe the *prize* be under an hundred tons burthen; nor above 15 l. if it be of greater burthen. *Ib* ſect. 7.

Commiſſioners of appeals in cauſes of *prizes* are to be appointed under the great ſeal: and appeals may be made to them within fourteen days after ſentence. *Ib.* ſect. 8.

Agents for *prizes* are to be choſen by the captors. *Ib.* ſect. 10. The treaſurer of the navy is to pay to the officers and ſeamen on board ſhips of war, or privateers, in any action where any ſhip of war, or privateer, ſhall have been taken from the enemy or deſtroyed, 5 l for every man on board ſuch *prize* or ſhip deſtroyed, at the beginning of the engagement. *Ib.* ſect. 15.

The captures of Flota ſhips, or galleons, or regiſter ſhips bound from Buenos Ayres, or Honduras, can be tried only in the high court of admiralty. *Ib* ſect. 17.

This ſtatute enacts ſeveral penalties and forfeitures for taking *prizes* by colluſion. Privateers forfeit the *prize*, half to the king, and half to the informer; and the commander of a man of war forfeits 1000 l. to be divided between the king and the informer *Ib.* ſect. 19.

PRO (*Cycl.*)—PRO *partibus liberandis*, in law, an antient writ for the partition of lands between co-heirs. Reg. orig. 316. *Blount*, *Cowel.*

PROBOLIUM, among the Romans, a kind of ſpear, which hunters uſed in hunting boars. *Pitiſc* in voc.

PROBOSCIPLECTANUS, in natural hiſtory, a name given by ſome authors to a peculiar and very elegant ſpecies of penicillus marinus, which has ſomewhat of a funnel-like ſhape, and has its mouth ſurrounded by a number of thin hair-like filaments. See PENICILLI *marini.*

The firſt who has deſcribed this particular ſpecies, is the accurate Fabius Columna, from whom Klein has engraved a figure of it. *Klein* de Tub. Mar. p. 1.

PROBOSCIS, (*Cycl.*)—PROBOSCIS *of flies.* See the article TRUNK.

PROBULEUMA, Προβούλευμα, among the Athenians, a decree or vote of the Areopagus, or ſenate of Athens.

It was ſo called becauſe agreed upon by the ſenate, with a deſign to have it afterwards propounded to an aſſembly of the people, that it might receive from them a farther ratification, without which it could not be paſſed into a law, nor have any force or obligatory power after the end of that year, when the ſenators and other magiſtrates laid down their commiſſions. *Potter*, Archæol. Græc. l. 1. c. 18. T. 1. p. 100.

PROCERS, in glaſs-making, iron inſtruments hooked at the extremity, uſed to ſettle the pots in their places, whether ſet too near or too far off. *Neri's* Art of Glaſs, Append.

PROCESSUS (*Cycl.*)—PROCESSUS *majoris muſculus*, in anatomy, a name given by ſome of the writers of the ear to one of the muſcles of that part, called by Cowper and others the *internus auris*, and by Albinus, more properly, the *tenſor tympani.*

PROCESSUS *minimi muſculus*, in anatomy, a name given by ſeveral authors to one of the muſcles of the ear, called by Cowper and others *obl quus externus*, and by Albinus *tranſverſus auriculæ*. See TRANSVERSUS *auriculæ.*

PROCESTRIA, among the Romans, buildings adjoining to camps, eſpecially winter quarters or ſtanding camps, where ſutlers, ſtrangers, traders, and others that followed the army, reſided; for they were not permitted to mix with the ſoldiers, unleſs when the enemy was near. *Pitiſc.*

PROCHARISTERIA, Προχαριστήρια in antiquity, a ſolemn ſacrifice which the Athenian magiſtrates yearly offered to Minerva, when the ſpring firſt began to appear. *Potter*, Archæol. Græc T. 1. p. 427

PROCHEILA, a word uſed by ſome authors to expreſs the extremities of the lips.

PROCHYMA, a word uſed by the antients to expreſs that kind of muſt which flows ſpontaneouſly from the grapes without their being preſſed.

PROCICADA, in natural hiſtory, a name given by ſome to the inſect which the French call *procigale.* It reſembles the cicada in moſt reſpects, but it has not the power of making the noiſe that inſect does. See PROCIGALE.

PROCIDENTIA (*Cycl.*)—PROCIDENTIA *uteri.* The firſt ſtep towards a cure of a *procidentia uteri*, or falling down of the womb, is to reduce it to its natural ſituation, and to keep it there by means of peſſaries. But as ſome diſadvantages attend the uſe of common peſſaries, Dr. Thomas Simſon has contrived one, and given us the deſcription and figure of it in the medical eſſays of Edinburgh, Vol. III. art. 18. See alſo the abridgment of this work, Vol II. p 224.

PROCIDENTIA *ani.* See the article TENESMUS, under which this is treated of.

PROCIGALE, in natural hiſtory, a name given by Reaumur, and from him by all the French naturaliſts, to a ſpecies of four-winged fly, greatly reſembling the cigale, or cicada, but wanting its power of making a noiſe.

This creature has a trunk of the ſame form with that of the cicada, very long, and laid cloſely upon the belly, and contained in a caſe or ſheath of the ſame ſtructure with that of this inſect. The female alſo has the ſame inſtrument at its tail, prepared for boring holes in wood, and called in that creature the *piercer*, and it uſes it to the ſame purpoſe, depoſiting its eggs by means of it in the branches of trees.

There is alſo another very ſmall inſect mentioned by Reaumur, as reducible to this claſs, if properly of the fly kind; but its ſmallneſs makes the ſtructure of its wings ſcarce diſtinguiſhable with any degree of accuracy; and it is hard to determine whether it has four wings, or two wings, and two caſes of wings: this little fly is extremely common on roſe-trees; its wings are yellowiſh, and its body white; and it can hop as well as fly. It is hardly poſſible to find a roſe-tree in the ſummer-months that is not loaded with theſe inſects, and they are principally found about the extremities of the young branches. The trunk of this ſmall fly is of the ſame kind with that of the cicada, and its buſineſs on the roſe-tree is the laying its eggs, in the ſame manner as the cicada, in the wood of the branches. This operation, however, is performed by a very different inſtrument; for inſtead of the piercer which the female cicada has at the end of her body, this little fly has a ſaw placed on the third ring of the body, and as much differing in ſhape as in poſition from the ſaw of the ſerrate roſe-fly, for it is leſs elegantly faſhioned; it is pointed, however, at the end, and the creature preſſing upon it with the whole weight of its body, forces it into the wood, by which means it makes a cavity, in which to depoſite its eggs. Theſe eggs are ſo ſmall and ſo tender, that they are not to be taken out of their place without breaking them. They finally produce ſmall worms, of a white colour and tenderer nature than the eggs themſelves: theſe, after they have fed a proper time on the juices of the branch leave their holes, and become transformed into nymphs, which yet have the power of moving and feeding, and greatly reſemble the nymphs of the cicada in that they perfectly ſhew the lineaments of the fly contained within them, differing ſcarce in any thing from it, except that they have caſes over their wings, which are ſo ſmall as to leave the rings of the body almoſt entirely bare. *Reaumur's* Hiſt Inſ Vol. IX. p. 241.

PROCINDYNEUONTES, Προκινδυνεύοντες, among the Romans, a deſignation given to the Velites, becauſe they were moſt expoſed to danger. The term anſwers to what we call the *forlorn-hope* See VELITES and FORLORN-HOPE, *Cycl.*

PROCONNESIUM *marmor*, a name given by the antients to a ſpecies of marble called alſo *neuris* and *elaphoneſus*, and by ſome *Cyzicus*, from the works of a famous ſtatuary of that name, many of which were made of it. It was of a bluiſh white, lightly variegated with black; this colour uſually running in ſmall veins, and not unaptly reſembling in many inſtances the courſe of the veins of a human body in the naked ſtatues. It was alſo uſed in the ſumptuous buildings of the Romans.

PROCUBITORES, among the Romans, an appellation given to the Velites, becauſe when the enemy was near, they always formed the outguard. *Pitiſc.*

PROCYON, in aſtronomy, a fixed ſtar of the ſecond magnitude, in the conſtellation canis minor.

PRODUCTION (*Cycl.*)—*Marine* PRODUCTIONS. To inveſtigate the nature of *marine productions*, Count Marſigli moiſtened in ſea-water ſome branches of coral, newly taken up, and found that the tubercles ſo frequent on its branches, after a little time all opened themſelves into regular flowers, each terminated by eight points. Theſe were white, and were ſuſtained by a cup divided into the ſame number of ſegments; and on the taking the branches again out of the water, he found theſe flowers all immediately cloſe themſelves up again, and only make red irregular tubercles; and the vigorous branches of coral retained this property of opening and cloſing their flowers for ſeven or eight days after they were taken out of the ſea. The tubercles, when wounded, yield a milky juice, in which, doubtleſs there is contained the ſeed of the coral.

When this curious naturaliſt had found coral to be a true plant in its organizations, it appeared a very deſirable thing to enquire whether it would yield vegetable principles, or thoſe of another kind, in a chemical analyſis. This experiment

ment he carefully tried, not only on coral but on many other of the ftony plants, and found all of them yielded the fame principles with vegetables. All of them yielded on this trial, a phlegm, a volatile urinous fpirit, with always more or lefs of a fea-water fmell, and a thick reddifh black fœtid oil; and the remainder in the retort being calcined, always yielded a fixt alkaline falt like that of plants.

The fea *productions* all afforded more or lefs of every one of thefe principles; but thofe of which ever kind that had been kept a long time after they were taken out of the fea, afforded always much lefs fluid matter than thofe which were frefh. Mr. Geoffroy was very defirous of following the Count in thefe refearches; and as he had no opportunity of procuring any frefh coral from the fea, he put into a retort a pound of the common red coral, fold by the druggifts, which is what wants the outer bark, and has ufually been a long time out of the fea. This yielded two drams and fix grains of a reddifh volatile urinous fpirit, and two or three grains of a fœtid oil, and the remainder in the retort by the common treatment, yielded afterwards near two drams of a lixivial falt of a faline tafte: the matter remaining after the lixiviation appeared a fort of lime.

The fpirit appeared to Mr. Geoffroy to be wholly the fame with that which the Count had himfelf fent to the academy under the title of the fpirit of old coral; and it appeared fcarce at all different from fpirit of hartfhorn. It turned fyrup of violets green, and made a white coagulation with the folution of corrofive fublimate. Tho' this was much the fame with the Count's fpirit, the falts drawn from the caput mortuum were, however, different; that made by Mr. Geoffroy making a white coagulation with a folution of corrofive fublimate, and that of Count Marfigli having no fuch effect; both the falts, however, turned the fyrup of violets green, and Mr. Geoffroy judged the difference in the other trial to be only from the Count's falt having been lefs carefully made, and containing fome quantity of earth which weakened its power and prevented this effect from it. It follows from all this, that the corals and all the other fea *productions* of that clafs are properly plants, tho' of the hardnefs of ftones: and in the internal ufe of coral it may be proper to confider it not as a mere abforbent, but as a fubftance which contains alfo a volatile fpirit and oil, which may well be fuppofed to poffefs virtues above thofe of mere abforbent earth; and that there is great difference between the virtues of fuch coral as has been long kept, and fuch as is newly taken up from the fea. The Count, after analyfing coral in this manner, tried the fame procefs on feveral parts of the rocks on which the coral grew; but he found this to yield none of thefe active principles; fo that altho' the hardnefs of corals and of ftones feems the fame, there is great difference between them in their principles, their nature, and effects.

There is yet one queftion remaining to be determined in this point, which is, what is the nature of this milky juice contained in the tubercles or flowers, and perhaps not lefs in the other parts of coral. The Count has faid nothing as to its qualities, but Boccone fays it is hot, acrid, and almoft cauftic; whence perhaps it is the natural fap of the plant, and is analogous to the milky juice of the fpurges and fome other plants. It were to be wifhed that this liquor could be tried with acids and alkalies, and in other ways, and its analyfis known: this perhaps would make our knowledge of the nature of this ftony vegetable perfect. Mem. Acad. Par. 1708.

PROEDRI, Προεδροι, among the Athenians, magiftrates whofe bufinefs it was to propofe to the people the things they were to deliberate upon and determine at every affembly, after which their offices expired. *Potter*, Archæol. Græc. l. 1. c. 17. T. 1. p. 93.

They were fo called from the privilege they enjoyed, of always having the firft feats at affemblies.

PROEROSIA, Προηροσια, in antiquity, the fame with *prerofia*. See PREROSIA.

PROFUNDUS, in anatomy, a name given by Albinus, Hunaud, and others, to a mufcle of the wrift, generally known by the name of the *perforans*. Thefe authors called, in the fame manner, the *perforatus* of others the *fublimis*.

PROGALL-INSECT, an animal nearly approaching to the gall-infect clafs, but differing from it in fome refpects, and called by this name from its refemblance to thofe creatures; as the creatures fomewhat approaching to the fcarab or beetle clafs, but not regularly of it, are called *profcarabs*.

This clafs of animals pafs a great part of their lives in the fame manner with the gall-infects, faftened to the bark of a tree, and there remaining motionlefs; fome of them alfo in the manner of the gall-infects cover their young brood with their bodies; but they are eafily diftinguifhable as animals, in all the ftages of their lives, and in that they differ from the others. The annular depreffions of their bodies may in all their ftates be diftinguifhed, efpecially with the help of a magnifying glafs; whereas thofe of the gall-infects all difappear as they grow towards their utmoft bulk.

If the gall-infects are worthy of obfervation on account of the great value of one fpecies of them, the kermes; the *progall-infects* are at leaft equally fo on the fame account, fince the cochineal belongs to this clafs.

The moft common and obfervable fpecies of the *progall-infect* clafs, is that of the elm, and a defcription of that alone may give a fufficient light into the hiftory of the whole clafs, and fhew what characters are to be found in the infects properly reducible to it.

This infect is principally found in the forked branches of the elm, and commonly in thofe of one, or at the utmoft of two years growth; it is fometimes found in other parts of the branches and twigs, but that is much lefs frequently. It is in the months of June and July that this infect is at its full growth; at this time, however, it appears to the naked eye only as a fmall oval convex mafs, of a dirty brownifh red colour, furrounded with a fmall downy white thread. This reddifh oval mafs is the back of the animal, and by the help of glaffes we may fee the annular ridges and depreffions that characterize the infect clafs. This is all that gives an idea of its being an animal; for it is at this time in a ftate of perfect immobility, and fhews neither head, legs, or any other part that might give a proof of what it is; all thefe parts are enveloped and hid by the cottony band that furrounds it, which fuffers no part but the convex furface of the back to be feen.

It is giving but a very imperfect idea of this downy rim, to call it only a border or pad laid round the body of the animal. This matter, in reality, makes a kind of neft in form of a bafket, in which the body of the infect is in a great meafure lodged. Its belly, which is placed on this neft, is feparated by it from the bark of the tree, and lodged on a fort of downy bed; the threads of this down are fomewhat thick and ftrong. The principal ufe this bed or neft feems deftined for, is, the reception of the young, which are produced in the end of June or in July. If the animal be removed from its bed at this feafon, a vaft number of fmall living animals are found in the bottom and fides of the neft. Thefe are of a yellowifh white, and have two fmall horns; their fhape much refembles that of the young gall-infects; their hinder part is more fharp than their fore part, and they run about very fwiftly on fix very fhort legs.

At whatever time however the *progallinfect* is removed from its neft, there are never found any eggs; the creature is viviparous, and the young animal feems to be born with its head foremoft, which is contrary to the manner of the pucerons and fome other fmall animals.

If the body of the parent *progall-infect* be crufhed in the month of June, a great number of fmall oblong bodies are always protruded; thefe are probably the embryo animals, tho' all that the niceft attention can in this ftate difcover in them, is, two fmall black fpecks, which afterwards prove to be the eyes. The nefts of thefe infects are feldom found fo full of young ones as might be expected; but that is probably owing to the length of time taken up in bringing forth fo great a number, probably eight or ten days, and the young ones in a day or two are perhaps fit to efcape and run away; fo that one finds only the laft born there.

The branches of the elm examined with the help of glaffes at this feafon, fhew us multitudes of the young *progall-infects* running about them; thefe, however, continue in this ftate but a little while, they foon choofe their place for fixing for life, and there remain without motion afterwards. They do not lofe the power of moving, however, till the month of April following; for till that time, if the branch on which they are be cut off, when it becomes dry, and furnifhes them no more juices, they will leave it and go in fearch of another; but after April, if the branch be cut off, they die upon the place when it dries, being no longer able to remove themfelves.

Thefe infects, like the gall-infects, do not grow much till after the winter is over: toward the end of April they have ufually arrived at their deftined bignefs; their bodies in the beginning of this month, and in fome part of March, are fomewhat reddifh; but this colour is the lefs to be diftinguifhed, as the rings are all bordered with fhort grey hairs. Thefe hairs are confiderably thick, but the animal is found abfolutely without them again, when it has its cottony bed under it, having then divefted itfelf of them in quitting its fkin, which it changes for one whofe pores are more proper to give paffage to the matter of which that bed is to be made. At all feafons their belly is of a redder colour than their back; and that is in a great meafure owing to the belly being always free from thofe grey hairs. The legs are very fmall and flender, in proportion to the fize of the animal; they are fix in number. Its trunk or fucker is not eafily difcovered, but is placed however in the fame manner with that of the gall-infect, and is like it in fhape.

The cottony matter forming itfelf by tranfpiration from the feveral parts of the animal, forms by degrees the neft, and as this increafes, the animal itfelf increafes alfo in bulk, and becomes gradually more and more red. No obfervation has yet been able to determine the manner of the fecundation of thefe infects; they are never feen to couple one with another, and moft probably the male of this clafs, as of the gall-infects, is a fmall fly. *Reaumur*'s Hift. of Infects, Tom. 4. p. 83.

PROGALL-INSECT, otherwife called COCHINEAL. There have been many conjectures about *cochineal*; but the moft probable feems to be, that it is an animal of the *progall-infect* clafs.

The

The *cochineal*, in the ftate in which it is brought to us, is in fmall bodies of an irregular figure, ufually convex, and ridged and furrowed on one fide, and concave on the other. The colour of the beft is a purplifh grey, powdered over with a fort of white duft. All that the world knew of it for a long time, was, that it was gathered from certain plants in Mexico, and therefore it was naturally fuppofed to be a feed. *Reaumur's* Hift. of Infects, Tom. 4. p 88.

In the year 1692, Father Plumier gave Pomet, the French author of a hiftory of drugs, an account of its being an animal: this, however, was difregarded; but Meffrs. Hartfoeker, De La Hire, and Geoffroy, afterwards evidently proved it to be one; and after this there were printed the depofitions in form of a number of perfons upon the fpot, who all declare it to be a viviparous animal, and that it paffes a great part of its life fixed to the vegetable body on which it feeds; and that it was a creature fubject to no change, nor ever appearing in any other ftate. Thefe and many other qualities found in the *cochineal*, all analogous to thofe of the clafs of *progall infects*, give great room to believe that it is truly and properly an infect of this clafs.

There are two kinds of *cochineal*, the finer called *meftique*, the other termed the wild *cochineal*. The firft is gathered from fuch plants of the opuntia as are prepared and managed properly on purpofe for the production of the animal, the other is found wild on the wild plant, and is much inferior to the *meftique* in value. The *meftique* has its name from the name of the place, where it is propagated in the greateft quantity, Meftique, in the Province of Honduras. As to the other, it is not yet determined whether it be another fpecies of the animal, or whether the fame fpecies in a lefs thriving condition Ibid. p. 91.

The Indians plant about their habitations the opuntias, on which they propagate and raife the *cochineal*; they gather feveral quantities of it in the year, and what they are moft afraid of in regard to it, is, a cold or a wet feafon. In fuch cafes they cut off the leaves of the plant ftored with the infects, and take them into their habitations. Thefe are of fuch a nature as not to dry and wither immediately, like the lefs fucculent plants, but often keep their juices long enough to furnifh the creatures a fufficient nourifhment, till the dangerous feafon is over. The infects are at this time in a ftate to produce their young; and the Indians place them in a fort of little nefts, twelve or fourteen together, on different parts of the opuntias of their plantation. Ibid. p. 93.

The animal is feldom more than three or four days in this condition, before it produces its young ones; each produces many thoufands, each fcarce fo large as the fmalleft mite; the young brood foon quit their neft, and like the other gall and *progall-infects*, wander about the plant for a little time, and then fix themfelves upon it in feveral places. They do not eat the plant, but only introduce their trunks and fuck the juice, and wherever they fix themfelves, which is ufually in the more fucculent parts of the plant, there they remain till they have acquired their full growth, and are in a condition themfelves to produce young ones. Ibid. p. 94.

The figure of this infect is oval, and its utmoft fize is that of a fmall pea. It has fix legs armed with claws, two eyes, and a trunk by which it fucks its nourifhment. Ibid. p. 95.

The ants, and many other little animals, are very fond of eating the *cochineals*; and it is with great difficulty that the Indians defend the young brood from thofe devourers. Ibid.

The firft of the gatherings of the *cochineal*, is at the time the Indians carry the parent animals to the plants; when thefe have produced their young they die in the nefts, and the Indians take down the nefts and take them out. The fecond gathering is three or four months after this, a little fooner or later, according to the feafon. The young ones produced from the former crop, have now acquired their full growth, and are ready to produce their young. In this fecond gathering they take care not to take off the whole generation, but leave enough on the plant to multiply and give them a new crop afterwards. About three or four months after this, they have another gathering from thefe. Soon after this the rainy feafon comes on, and the young ones produced from what are left on the plants from this gathering, are what the Indians houfe, for the parents of the next year's crops. The laft of thefe crops is the leaft valuable, being generally foul and full of fmall infects of the new brood, among the right and full grown ones. Ibid. p. 96.

After the Indians have gathered the *cochineal* they kill it, otherwife they would loofe a great part of their harveft; for the parent race would live fome days after their being taken from the plant, and would produce their young, which would be nimble enough to run away in great numbers. Some to kill the creatures plunge them in hot water, and afterwards dry them in the fun; others kill them by a proper degree of heat. Ibid. p. 97.

The living *cochineals* are covered, like all other infects of this kind, with a kind of white powder; but in the water ufed to kill them they loofe much of this powder, and are therefore of a different colour from thofe killed by heat. Ibid. p. 98.

The accounts from the place where the *cochineal* is produced, give us all thefe particulars; but to decide the long difputed point, whether they are of the animal or vegetable kingdom, we have the means in our own hands even in this part of the world. We need only moiften and foak in water, or in vinegar, a number of *cochineals* till they are fwelled and diftended, to know that every one is the more or lefs perfect body of an infect; the moft imperfect and mutilated fpecimens always fhew the rings of the body, and from obferving others it will be eafy to find the number and difpofition of the legs; parts, or even whole ones being left on feveral, and often compleat pairs. Ibid. p. 100.

People of warm imaginations no fooner knew it to be an infect, but before they were perfectly acquainted with its form, they were for alloting it its proper clafs. Some would have it to be a worm, others a fpider, and others a beetle. Petiver is of the number of the laft, and has been fanguine enough to figure it in all the ftates he fuppofed it to have paffed, the hexapode worm, the nymph, and the perfect beetle; tho' we now find by pofitive accounts from the place, that it undergoes no change at all, and from its whole figure and hiftory, that it is properly of a clafs of animals then not known. Many have alfo been of opinion, that it was only a part of an animal, but a clofer and repeated obfervation would have fhewn them that it comes to us often more perfect than is imagined, and frequently wants only its horns and a leg or two, of being a perfect animal.

It is eafy to fee in fome of thefe the head, and fometimes a tubercle on each fide of it, which may very naturally be fuppofed the eyes, or elfe the roots of the antennæ or horns. The firft pair of legs are thus found to be very near the head of the animal, and placed exactly as in all the gall-infect and *progall-infect* clafs; a little above thefe one may diftinguifh alfo the remainder of the trunk fituated exactly as in the gall infects and *progall-infects*; the anus is alfo eafily diftinguifhed. Ibid. p. 101.

As the manner of the fecundation of the gall-infects was fo long unknown in Europe, it is no wonder that that of the *cochineal* fhould not be very early difcovered in Mexico: but we have an account among Mr. Ruyfche's pieces from whence almoft all the true hiftory of this animal is had, that at the feafon of the *cochineals* becoming big, there is feen continually among them a fmall butterfly, which is bred upon the fame plants, and by means of which the *cochineals* conceive This is fo ftrictly analogous to the manner of the gall-infect clafs, that there is no room to doubt the fact; and it is a farther great proof, how little truth was before in the gueffes concerning the clafs of animals this belonged to. Ibid. p. 103.

It would be an eafy miftake for any one not profeffedly a naturalift to miftake the male gall-infect for a butterfly, as it has white opake wings; and affuredly the male *cochineal* is an animal of the fame fpecies, a true two winged fly.

If a full grown *cochineal* be foaked a confiderable time in water or vinegar, and afterwards gently preffed, there will frequently be protruded from its hinder part a number of fmooth oblong bodies, which might be eafily miftaken for eggs; but a good microfcope will fhew in thefe the traces of the legs and other lineaments fufficient to prove it to be a true embryo fœtus. Ibid p. 104.

The wild *cochineal* differs from the *meftique* in being lefs pure, and confifting of animals of all ages and fizes, as being gathered with lefs care, and without the intent of propagating future crops; the larger fpecimens in this fometimes exceed the finer *cochineal* in fize, and when moiftened and fqueezed, fend forth vaft numbers of the fame oblong bodies. Ibid. p. 105.

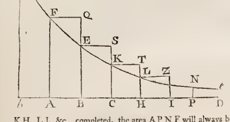
Duhamel, while he refided at St. Domingo, found in that ifland the fame animal which Father Plumier had before obferved there, and accounted the fame creature with the *cochineal* infect; be gathered fome of thefe animals from off the opuntias there, and fent them over to Paris; they were found to have all the exterior marks of *cochineal*; but it is much to be feared they are really no more than that to the *cochineal*, which the common peach and vine gall-infects are to the kermes of the ilex. Poffibly, however, a proper care and attention, and the bringing over the very creatures from Mexico to other parts of the world, might, with many tryals to determine what fpecies of the opuntia it is that they moft thrive on, be a means of propagating them to vaft advantage. Ibid. p. 108.

Joffelin, in his account of the products of New England, mentions a particular kind of fun-flower, called by fome a fpecies of *golden-rod*; the ftalks of which are covered about the knots in the fummer months with infects of the fize of large fleas. Thefe preferved in a proper manner, yield a very elegant fcarlet colour, and the author thinks might be made to fupply the ufe of *cochineal*.

PROGRESSION *(Cycl.)*—As a right line, or figure, may increafe continually, and never amount to a given line or area; fo there are *progreffions* of fractions which may be continued at pleafure, and yet the fum of the terms be always lefs than a given number. If the difference between their fum and this number decreafe in fuch a manner, that by continuing the *progreffion* it may become lefs than any fraction how fmall foever, that can be affigned; this number is the limit of the fum of the *progreffion*, and is what is underftood by the value of

of the *progression*, when it is supposed to be continued infinitely. These limits are analogous to the limits of figures, and they mutually assist each other. The areas of figures can, in many cases, be no otherwise expressed than by such *progressions*; and when the limits of figures are known, they may sometimes be advantageously applied for approximating to the sums of certain *progressions*.

Thus, for instance, let the terms of any *progression* be represented by the perpendiculars A F, B E, C K, H L, &c. standing at a given distance on the base A D; and let P N be any ordinate of the curve, F N e passing over the extremities of those perpendiculars. Suppose A P to be produced; then according as the area, A P N F, has a limit to which it may approach continually, but never exceed, or may be produced till it exceed any given space; there will also be a limit of the sum of the *progression*, or it may be continued till it exceed any given number. For supposing the rectangles F B, E C,



K H, L I, &c. completed, the area A P N F will always be less than the sum of those rectangles, but greater than their sum after the first. Therefore the area A P N F, and the sum of those rectangles, either both have limits, or both have none. The same is to be said of the sum of the ordinates A F, B E, C K, H L, &c. and of the sum of the terms of the *progression* represented by them. If the curve, F N e, for example, be the common hyperbola, b its center, b P the asymptote; and A B being equal to b A, if A F represent unity, the series of ordinates will represent the *progression* $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}$, &c. which may therefore be continued till it exceed any given number, as the hyperbolic area may be produced till it exceed any given space[a]. But if F N e be an hyperbola of any higher order, so that the ordinate P N be reciprocally as any power of the base b P, whose exponent is greater than unity, the area A P N F[b], and the sum of the *progression* represented by the series of ordinates, will have limits. Hence there is always a limit of the sum of the fractions that have unity for their common numerator; and the squares, cubes, or any other powers of the numbers, 1, 2, 3, 4, &c. whose exponents exceed unity for their successive denominators[c].

[[a] See HYPERBOLA. [b] Ibid. [c] See *Maclaurin*'s Fluxions, B 1. p. 290.]

When the area A P N F has a limit, we may not only conclude, that the sum of the *progression* represented by the ordinates has a limit; but when the former limit is known, we may by it approximate to the value of the latter: and *vice versa*, when the limit of the *progression* is given, the limit of the area may be found. See *Maclaurin*, Lib. cit. Art. 352, 353.

Progressions of fractions may be found at pleasure, that shall have assignable numbers equal to the limit of the sum of the terms. Thus a series or *progression* of any number of quantities continually decreasing being given, their successive differences form a new series of terms, the sum of which from the beginning is always equal to the excess of the first term of the first series above its last term. For instance, if A, B, C, D, E, &c. be the terms of the first series, it is manifest that the sum of the difference of A and B, B and C, C and D, D and E, is the excess of A above E. If the terms of the first series decrease in such a manner, that by continuing the *progression* they may become less than any quantity that can be assigned, then the first term of the first series is the limit of the sum of the second series. In like manner, the difference of the alternate terms of the first series, as of A and C, B and D, C and E, &c. form a new *progression* of terms, the sum of any number of which is equal to the excess of the sum of A and B, the first and second term of the series, above the sum of the last and penultimate terms; and the sum of A and B is the limit of the sum of the new series. In general, if a *progression* is formed by taking the difference of the first term A, and the term whose place in the series is expressed by any number n; of the second term B, and that whose place is $n+1$; of the third term C, and that whose place is $n+2$, and so on; then will the limit of the sum of this new *progression* be equal to the sum of the terms A, B, C, D, &c. which precede that term whose place is expressed by n. In this manner *progressions* may be found at pleasure, which may be continued without end, and have given numbers for the limits of their sums.

For example, let the first series be $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}$, &c. the successive differences of the terms of which are $\frac{1}{2}, \frac{1}{6}, \frac{1}{12}, \frac{1}{20}$, &c. and the limit of the sum of this *progression* will therefore be 1.

If we multiply each term of this last series by 2, that the first term may be unit, we shall have $1, \frac{1}{3}, \frac{1}{6}, \frac{1}{10}$, &c. the denominators of which are the triangular numbers, unity being the common numerator, and the limit of the sum of this *progression* is 2. The successive differences of the terms of this latter series being each multiplied by $\frac{3}{2}$, that the term of the new series may be unity, give $1, \frac{1}{4}, \frac{1}{10}, \frac{1}{20}$, &c. which have the pyramidal numbers for their successive denominators; and the limit of the sum of this *progression* is $\frac{3}{2}$. In the same manner, the limit of the sum of the fractions having unity for their common numerator, and the figurate numbers of any order denoted by m for their successive denominators, is found to be $\frac{m-1}{m-2}$.

The same series $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}$, &c. being again assumed, the differences of the alternate terms are $\frac{2}{3}, \frac{2}{8}, \frac{2}{15}, \frac{2}{24}$ &c. the limit of the sum of which *progression* is $1\frac{1}{2}$. Dividing each term by 2, the limit of the sum of $\frac{1}{3}, \frac{1}{8}, \frac{1}{15}, \frac{1}{24}$, &c. is $\frac{3}{4}$. If we take the differences of the first term, and that whose place is m, the second term and that whose place is $m+1$, &c. the common numerator of those differences will be $m-1$; and their successive denominators, the products of $1 \times m$, $2 \times \overline{m+1}$, $3 \times \overline{m+2}$, &c. and the limit of the sum of this *progression* is the sum of as many terms $1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}$, &c. as there are units in $m-1$. Now if each term of the new *progression* be divided by $m-1$, that unity may be the common numerator, the terms $\frac{1}{m}$, $\frac{1}{2 \times \overline{m+1}}$, $\frac{1}{3 \times \overline{m+2}}$, &c. will arise, the limit of which is equal to the sum of the fractions $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$, &c. (continued till their number be $m-1$) divided by $m-1$. In like manner, by assuming other alternate, or any equivalent terms of the series $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$, &c. we may form new *progressions*, the value of which may be found. Thus, if we take the terms $1, \frac{1}{5}, \frac{1}{9}, \frac{1}{13}$, &c passing over three terms, and divide the successive differences of these terms by 96, we shall have the series $\frac{1}{5.24}, \frac{1}{5.9.24}, \frac{1}{9.13.24}, \frac{1}{13.17.24}$, &c. which is equivalent to the series C, given by Monf. de Monmort, in the philosophical transactions, N°. 353, p. 651. viz.

$$C = \frac{1}{1.2.3.4.5} + \frac{14}{5.6.7.8.9} + \frac{55}{9.10.11.12.13} + \frac{140}{13.14.15.16.17.}$$

+ &c. The sum of which will therefore be $\frac{1}{96}$. And if we take the alternate terms of the series $\frac{1}{2}, \frac{1}{12}, \frac{1}{30}, \frac{1}{56}$, &c. above mentioned and divide the successive differences of the terms by 2, we shall have the series $\frac{5}{2.12}, \frac{9}{12.30}, \frac{13}{30.56}$, &c. which is equivalent to the series $\frac{5}{1.2.3.4.}, \frac{9}{3.4.5.6}, \frac{13}{5.6.7.8}, \frac{17}{7.8.9.10}$, &c. mentioned in the said philosophical transactions, and marked A, the sum or limit of which, by the foregoing rule, will be $\frac{1}{4}$. So the limit of M. Monmort's series $B = \frac{1}{1.2.3.4.5} + \frac{4}{4.5.6.7.8}$, &c. will be $= \frac{1}{108}$ See *Maclaurin*'s fluxions, art. 356, where there is an error of the press, in p. 296. l. 11. and 15. for the series which in line 11. is said to be Mr. Monmort's series B, is the series A, p. 651. of the philosophical transactions, N°. 353 aforesaid; so in line 15, for A, read B.

This may suffice to shew how the sums of *progressions* so derived may be found. We refer for the farther application of these principles to the aforesaid treatise of fluxions, art. 357, &c. Mr. Stirling's[a] treatise of the summation of series, ought also to be consulted, as he has improved the method of approximating to the value of *progressions*, which often arise in the solution of problems. See also Mr. de Moivre's *miscellanea analytica*, and particularly the supplement to that work [[a] *Methodus differentialis*: sive *tractatus de summatione et interpolatione serierum infinitarum*. Lond 1730. 4°.]

PROGYMNASMATA, Προγυμνάσματα, in antiquity, certain preparatory exercises performed by all those who offered themselves to contend in the Olympian games. *Potter*, Archæol. l. 2. c. 22. T. 1. p. 448.

PROHIBITO, in the Italian music, is a term applied to such parts of a piece as are not proper, or according to just rule. Thus *intervallo prohibito* is every interval in melody that does not pass the ear easily or naturally, to give it some pleasure; such are the tritone, the sixth major, the seventh, ninth, &c. though under certain circumstances, even these have pleasing effects, in that by their harshness they render the subsequent concords more agreeable.

PROJECTILE (*Cycl.*)—The theory of *projectiles*, as delivered under this head in the Cyclopædia, and by almost all writers on gunnery since Galileo, proceeds on the supposition, that the flight of shot or shells is nearly in the curve of a parabola. Galileo, indeed, has shewn, that independently of the resistance of the air, all *projectiles* would in their flight describe a parabola; and did propose some means of examining what inequalities would arise from that resistance. So that it might have been expected, that those who came after him would have tried how far the real motions of *projectiles* deviated from a parabolic tract, in order to have decided how far

far the reſiſtance of the air was to be attended to, in the determinations of gunnery. But inſtead of proceeding thus cautiouſly, ſubſequent writers have boldly aſſerted, that no conſiderable variation could ariſe from the reſiſtance of the air, in the flight of ſhells and cannon-ſhot; and it is now become an axiom almoſt generally acquieſced in, that the flight of theſe bodies is nearly in the curve of a parabola.

This hypotheſis was ſupported by Anderſon in his Treatiſe *of the genuine uſe and effects of the gun*, publiſhed in 1674; alſo by Monſ Blondel in his *Art de jetter les Bombes*; and the ſame ſubject being treated of by Dr Halley in the Phil. Tranſactions, N°. 216. this learned gentleman, ſwayed by the conſideration of the great diſproportion between the denſity of bullets and of the air, thinks it reaſonable to believe, that the reſiſtance of the air to large metal ſhot is ſcarcely diſcernible, although in light ſhot he acknowledges it ought to be accounted for. But though this hypotheſis was readily admitted by thoſe who contented themſelves with ſpeculation only, yet Anderſon himſelf found it impoſſible to reconcile it to experience, without ſome modification. This led him to ſuppoſe that a bullet at its firſt diſcharge, flew a certain diſtance in a right line, from the end of which line only it began to bend into a parabola. By this means he defended, as he thought, the hypotheſis of a parabolic motion: but ſo ſtrange a ſuppoſition as that of the ſuſpenſion of the action of gravity, needs no confutation. Anderſon was deceived, by his not knowing how greatly the primitive velocity of the heavieſt ſhot is diminiſhed in the courſe of its flight by the reſiſtance of the air.

Practical gunners alſo unanimouſly agree, that every ſhot flies in a ſtreight line to a certain diſtance from the piece, which imaginary diſtance they call the extent of the point-blank ſhot. This flight in a ſtreight line, indeed, ſuppoſing it fact, would be not only a refutation of the parabolic hypotheſis, but a moſt unaccountable difficulty in itſelf, as implying a ſuſpenſion of the action of gravity. But the great velocity of cannon-ſhot, aſſigned by Mr. Robins, ſeems readily to clear up this affair. We need only ſuppoſe, that within the diſtance thus determined by practical gunners, the deviation of the path of the ſhot is not very perceptible in their way of pointing. Now as a ſhot of 24 lb. fired with two thirds of its weight in powder, will, at the diſtance of five hundred yards from the piece, be ſeparated from the line of its original direction, by an angle of little more than half a degree; thoſe who are acquainted with the inaccurate methods often uſed in the directing of cannon, will eaſily allow, that ſo ſmall an aberration as this, may, by the generality of practitioners, be unattended to, and the path of the ſhot may conſequently be deemed a ſtrait line, eſpecially as other cauſes of error will often intervene, much greater than what ariſes from the incurvation of this line by gravity. See new princip. of Gunnery, p. 82.

How raſh and erroneous the opinion of the inconſiderable reſiſtance of the air is, will eaſily appear from what is eſtabliſhed by that ingenious author, who has ſhewn that this reſiſtance to a cannon ball amounts to more than twenty times the weight of the ball. What errors may not be expected from an hypotheſis which neglects this force as inconſiderable? In effect, it will not be difficult to ſhew, that the track deſcribed by the flight of ſhot or ſhells, is neither a parabola nor nearly a parabola. For by that author's experiments it appears, that a muſket ball of three fourths of an inch diameter, fired with half its weight of powder from a piece 45 inches long, moves with the velocity of near 1700 feet in a ſecond. Now, by the common parabolic theory if this ball flew in the curve of a parabola, its horizontal range at 45°, would be found to be about 17 miles. But from practical writers, as Diego, Ufano, and Merſennus, it appears, that this range is ſhort of half a mile; ſo that a muſket ſhot at 45° elevation, with a reaſonable charge of powder, flies not the $\frac{1}{34}$ part of the diſtance it ought to do if it moved in a parabola.

Nor is this great diminution of the horizontal range to be wondered at, when it is conſidered that the reſiſtance of the air to this bullet, when it firſt iſſues from the piece, amounts to 120 times its gravity.

Again, if the flight of the heavieſt ſhot, in common uſe for land ſervice, as of iron bullets of 24lb. weight, be examined, it will appear, that ſuch a ſhot made with a full charge of powder has a velocity of 1650 feet in 1″. And the horizontal range at 45° of this ſhot, would, according to the parabolic hypotheſis, be about 16 miles; but by the experiments of St. Remy it appears, that the range is really ſhort of three miles; which is not one fifth of the diſtance it ought to fly, if it deſcribed the curve of a parabola.

And this deviation from the parabola, happens not only in theſe great velocities, but in ſuch as are much leſs; thus in velocities of about 400 feet in 1″; by ſeveral experiments it appears, that the range of a leaden bullet of three fourths of an inch in diameter, fired at different elevations with this velocity, did not at all anſwer the common theory. So that it ſufficiently appears that this theory, or the ſuppoſition of the inconſiderableneſs of the air's reſiſtance to *projectiles*, is falſe.

Indeed the falſeneſs of this hypotheſis almoſt appears at ſight, even in *projectiles* ſlow enough to have their motion traced by the eye; few there are who do not deſcend thro' a curve manifeſtly ſhorter and more inclined to the horizon than that in which they aſcended, and the higheſt point of their flight, or the vertex of the curve, is much nearer to the place where they fall on the ground than from whence they were at firſt diſcharged. Theſe things cannot be a moment doubted of by any one, who in a proper ſituation views the flight of ſtones, arrows, or ſhells, thrown to any conſiderable diſtance. See new princip. of Gunnery, Part 2. Prop. 6.

What is here advanced may be confirmed from the conſtant obſervation of all who are converſant in the practice of throwing bombs, *viz.* that the ranges at elevations below 45°, conſtantly exceed the ranges at elevations above 45°, which are reſpectively at an equal diſtance from 45°. Thus the range of ſhells at 15°, will go farther than one at 60°, and ſo a range at 20° exceeds one at 65°, *&c.* but it is known that in the parabolic hypotheſis theſe ought to be equal, which hypotheſis is therefore falſe.

There is an odd phænomenon in the motion of bodies projected with conſiderable force, which ſhews the great complication and difficulty of this ſubject. The phænomenon is, that bullets in their flight are not only depreſſed beneath their original direction by the action of gravity, but are alſo frequently driven to the right or left of that direction by the action of ſome other force.

If it was true that bullets varied their direction by the action of gravity only, then it ought to happen that the errors in their flight to the right or left of the mark they were aimed at, ſhould increaſe in the proportion of the diſtance of the mark from the piece only. But this is contrary to all experience; the ſame piece which will carry its bullet within an inch of the intended mark, at 10 yards diſtance, cannot be relied on to 10 inches in 100 yards, much leſs to 30 inches in 300 yards.

Now this inequality can only ariſe from the track of the bullet being incurvated ſideways as well as downwards; for by this means the diſtance between the incurvated line, and the line of direction, will increaſe in a much greater ratio than that of the diſtance; theſe lines being co-incident at the mouth of the piece, and afterwards ſeparating in the manner of a curve from its tangent, if the mouth of the piece be conſidered as the point of contact.

This is put beyond diſpute from the experiments made by Mr. Robins; who informs us, that having taken a barrel carrying a ball of three fourths of an inch diameter, and fixing it on a heavy carriage, he ſatisfied himſelf of the ſteadineſs and truth of its direction, by firing at a board one foot and a half ſquare, and miſſing it but once in 16 ſucceſſive ſhot. Now the ſame barrel being fixed on the ſame carriage, and fired with a ſmaller quantity of powder, ſo that the ſhock on the diſcharge would be much leſs, and conſequently the direction leſs changed, he found that at 760 yards diſtance the ball flew ſometimes 100 yards to the right of the line it was pointed on, and at other times 100 yards to the left. He found too that its direction in the perpendicular line was not leſs uncertain, it falling one time above 200 yards ſhort of what it did at another; altho' by the niceſt examination of the piece after the diſcharge, it appeared not to have the leaſt ſtarted from the poſition it was placed in. New principles of Gunnery, Part. 2. Prop. 7.

If it be aſked what can be the cauſe of a motion ſo different from what has been hitherto ſuppoſed? it may be anſwered, That the deflection in queſtion muſt be owing to ſome power acting obliquely to the progreſſive motion of the body, which power can be no other than the reſiſtance of the air. And this reſiſtance may perhaps act obliquely to the progreſſive motion of the body, from inequalities in the reſiſted ſurface; but its general cauſe is doubtleſs a whirling motion acquired by the bullet about its axis; for by this motion of rotation, combined with the progreſſive motion, each part of the bullet's ſurface will ſtrike the air in a direction very different from what it would do if there was no ſuch whirl; and the obliquity of the action of the air ariſing from this cauſe will be greater, according as the rotatory motion of the bullet is greater in proportion to its progreſſive motion.

PROLAPSUS *oculi*, in ſurgery, a diſtemperature of the eye, in which it is ſo violently inflamed and ſwelled, that it cannot be retained in its orbit or ſocket, but protrudes itſelf out of its natural ſeat. This diſorder is not only attended with great deformity, but alſo intenſe pains, blindneſs, and too often an obſtinate cancer are the effects of it. This is ſometimes ſo violent in degree, that the eye burſts out of its coats.

This diſorder ſometimes ariſes from inflammations, or redundancy of humors; and ſometimes from external violence, or from a cancer. Sometimes, when the diſorder is recent, and but in a moderate degree, it may be carried off by bleeding, bliſtering, and purging, with external applications, as fomentations and the like. When it will give way to none of theſe, the tumor muſt be opened, and the humors diſcharged, and this repeated as often as neceſſary; after every dreſſing, binding on a plate of lead hollowed in a proper degree.

When the natural figure of the eye, and its office of viſion are wholly deſtroyed by this diſeaſe, and the pains become

more intenſe, there is no way left but to make a large inciſion and let out the humors of the eye, and afterwards cut away ſo much of it, that the remainder may be covered with the eye-lid *Heiſter*'s Surg. p. 427.

PROLAPSUS *uvulæ*. The *uvula* is ſometimes ſo much enlarged and elongated, as to reach the larynx and pharynx, and obſtruct the actions both of reſpiration and deglutition, as well as of ſpeech. If it proceeds from a recent inflammation, the patient may be relieved by bleeding and cooling gargles, with ſal armoniac and alum; ſcarifications are alſo very uſeful in this caſe, to prevent its ſpreading and inflammation.

When, on the other hand, this part is too much enlarged and elongated by phlegmatic humors, it appears white and free from pain and inflammation, and is moſt relieved by a gargle of ſpirit of wine and water warm, or a decoction of red roſes, or the like aſtringent ſubſtances with ſpirit of wine, or ſpirit of ſal armoniac added in ſmall quantities to them.

A powder of ginger, pepper, and pomegranate peel, may alſo be applied; but when all theſe methods prove ineffectual, the only remaining one is, to take off as much of the *uvula* as is neceſſary, either by ligature or by the ſciſſars. This latter is much the eaſier and better way; and the great caution neceſſary in it is, neither to take off too much nor too little of the *uvula*. For if too much be taken off, the patient's voice will be the worſe for it afterwards; and if too little, he will be very little the better for the operation.

This is a very common diſorder among the peaſants in Norway, and they have invented a machine with a hole in it, to let thro' a proper portion of the *uvula* when the whole is thruſt into the mouth, and a ſpring knife, which cuts off juſt as much as is let thro'. The ſurgeons have copied and improved on this invention. *Heiſter*'s Surg. p. 470.

PROLATION, *(Cycl.)* in muſic. The ſigns by which the modern antients uſed to ſignify a *prolation* to be made on any note, was a point in a circle or ſemi-circle, thus, ⊙, Є. This point was the length of a ſemi-breve and minim.

Prolation was either *perfect* or *imperfect*. *Perfect prolation* was marked after the cleff as above, and then the ſemi-breve contained three minims, for which reaſon they placed the figure 3, or $\frac{3}{2}$, or $\frac{3}{1}$, after the circle, to ſignify that three ſuch notes were required to a bar. See example A.

Imperfect prolation was marked with the ſame characters, but without points, and then the ſemi-breve contained but two minims. See example B.

A B

Theſe characters are almoſt entirely diſuſed in the modern practice; but as they are often met with in antient muſic, 'tis therefore neceſſary that a muſician ſhould have ſome knowledge of them. Tho' even now the Italians have two ſorts of *prolation* in muſic, which are ſignified by characters reſembling thoſe above deſcribed in the example A. The firſt they call *prolatione maggiore perfetta*, and it is marked thus, ⊙ and $\frac{3}{2}$. The ſecond they call *prolatione minore perfetta*, the characters of which are, Є, or $\frac{3}{1}$, or $\frac{3}{2}$, but oftener C and $\frac{3}{2}$; but in both caſes the ſemi-breve contains a whole bar, and its pauſe the ſame; the minim one third of the bar, and its pauſe the ſame; and ſo of the reſt in proportion.

Prolation is alſo uſed for a ſeries of ſeveral ſounds or notes on the ſame ſyllable or vowel.

PROLECTATIO, a word uſed in chemiſtry to expreſs an extraction of the finer ſubſtances of a mixed body by the attenuation of the ſubtler particles; ſo that theſe being rarefied, ſeparate ſpontaneouſly from the reſt, and leave the groſſer and leſs valuable part in form of a reſiduum behind.

PROLEPTICOS, an epithet uſed by the antients to expreſs a fever the fits or exacerbations of which were apt to return before their regular time.

PROLOGIA, Προλογια, in antiquity, a feſtival celebrated by the inhabitants of Laconia, before they gathered their fruits. *Potter*, Archæol Græc. T. 1. p. 427.

PROMACHIA, Προμαχια, in antiquity, a feſtival in which the Lacedæmonians crowned themſelves with reeds. *Potter*, Archæol. T. 1. p. 427.

PROMALACTERION, the name of the firſt apartment in the hot baths of the antients; this was a hot and cloſe room, in which the perſon was kept a while before he plunged at once into the warm water.

PROMETHEIA, Προμηθεια, in antiquity, an Athenian ſolemnity celebrated in honour of Prometheus, with torch-races, in remembrance that he was the firſt that taught men the uſe of fire. *Potter*, Archæol. Græc. T. 1. p. 427.

PROMYTHION, Προμυθιον, in rhetoric. See FABLE, *Cycl.*

PRONATOR *(Cycl.)*—PRONATOR *quadratus, ſive tranſverſus*, a ſmall fleſhy muſcle nearly as broad as it is long, lying tranſverſely on the inſide of the lower extremity of the fore arm

It is fixed by one ſide or edge in the long eminence, at the lower part of the internal angle of the ulna, and by the other in the broad concave ſide of the lower extremity of the radius. It is wholly fleſhy, without any mixture of tendinous fibres. It is ſituated tranſverſely; but that extremity which lies on the radius is nearer the carpus than that on the ulna. It is of a moderate thickneſs; the fibres neareſt the ſurface are longeſt, the reſt decreaſing in proportion as they lie nearer the interval between the two bones, and the interoſſeous ligament. It has a ligamentary or tendinous frænum belonging to it, one end of which is fixed in the interoſſeous ligament, the other in the inner edge of the baſis of the radius. *Winſlow*'s Anatomy, p. 190.

PRONATOR *teres ſive obliquus*, a ſmall muſcle broader than it is thick, ſituated on the upper part of the ulna, oppoſite to the ſupinator brevis, with which it forms an angle like the letter V.

It is fixed to the internal condyle of the os humeri, partly by fleſhy fibres, and partly by a tendon common to it with the ulnaris internus; from thence it paſſes obliquely before the extremity of the tendon of the brachiæus, and reaches to the middle part of the convex ſide of the radius; where it becomes flat, and is inſerted below the ſupinator brevis, by an extremity almoſt wholly fleſhy.

It is called *teres*, to diſtinguiſh it from the quadratus; but the name of *pronator ſuperior* is much more proper; but that of *pronator obliquus* is certainly propereſt of all. *Winſlow*'s Anatomy, p. 190.

PRONG-*hoe*, in huſbandry, a term uſed to expreſs an inſtrument uſed to *hoe* or break the ground near, and among the roots of plants.

The ordinary contrivance of the *hoe* in England is very bad, it being only made for ſcraping on the ſurface; but the great uſe of *hoeing* being to break and open the ground, beſide the killing the weeds, which the antients, and many among us have thought the only uſe of the *hoe*, this dull and blunt inſtrument is by no means calculated for the purpoſes it is to ſerve.

The *prong-hoe* conſiſts of two hooked points of ſix or ſeven inches long, and when ſtruck into the ground will ſtir and remove it the ſame depth as the plough does, and thus anſwer both the ends of cutting up the weeds and opening the land. The antient Romans had an inſtrument of this kind, which they called the *bidens*; but they were afraid of its uſe in their fields and gardens, and only uſed it in their vineyards. The *prong-hoe* comes into excellent uſe even in the horſehoing huſbandry; in this the *hoe*-plough can only come within three or four inches of the rows of the corn, turneps and the like; but this inſtrument may be uſed afterwards, and with it the land may be raiſed and ſtirred, even to the very ſtalk of the plant *Tull*'s Huſbandry

PRONOMÆA, a word uſed by ſome naturaliſts to expreſs what is uſually called the trunk, or proboſcis in inſects; an inſtrument ſomewhat reſembling the trunk of an elephant, which moſt of thoſe ſmall animals are provided with for the extracting the juices of plants, &c deſtined for their food.

PRONTIA *lapis*, a name given by the writers of the middle ages to a foſſile of which they relate ſeveral extraordinary things; but their reſembling it to the head of a tortoiſe, and giving it the virtue of preſerving people from injuries by lightning, ſeem to make it plain that the word is only a corrupt ſpelling of the *brontia* of the antients, of which Pliny has related the ſame things.

This was a ſpecies of echinites, ſuppoſed to fall from the clouds in thunder ſtorms. See BRONTIA.

PROOF *(Cycl.)*—PROOF, in the ſugar trade, a term uſed by the refiners of ſugar for the proper ſtate of the diſſolved ſugar when it ſhould be ſet to harden

The proceſs in the bringing ſugar to this ſtate may be underſtood by performing the whole work in little in this manner: Take ſix pounds of coarſe, or unrefined ſugar, diſſolve it over the fire in ſix pints of lime water; add to this the whites of four eggs beat up to a froth, ſtir the whole together; then boil the liquor to a higher conſiſtence than a ſyrup, or till, when expoſed to the cold it will concrete into grains. This is what the ſugar-bakers call *proof*. Pour this ſyrup into an earthen mould, with a hole at its bottom, ſtop the hole and ſet the veſſel in a moderately warm place.

The ſugar in a few days will ſet and harden, then open the hole at the bottom, and lay over the top of the ſugar ſome tobacco-pipe clay, made into a ſoft pap with water. The clay muſt be afterwards weted at times, and the water from among it will gradually be ſoaked up by the ſugar, and running thro' it will waſh away the treacle, without diſſolving the grained part. And thus all the treacle will by degrees be drained out of the maſs, and a loaf of white ſugar procured. *Shaw*'s Lectures, p. 149.

PROOF *ſpirits*, among diſtillers. See SPIRITS.

PROPAGATION *(Cycl.)* — PROPAGATION *of plants*. The number of vegetables that may be *propagated* from an individual, is very remarkable, eſpecially in the moſt minute plants.

It has been recorded, that in ſo large a plant as the common mallow, the annual product of one ſeed was no leſs than 200,000; but it has been ſince proved, by a ſtrict examination into the more minute parts of the vegetable world, that ſo deſpiſed a plant as the common wall maſs produces a much more numerous offspring. In one of the little heads of this plant

plant there have been counted 13824 seeds. Now alloting to a root of this plant eight branches, and to each branch six heads, which appears to be a very moderate computation, the produce of one seed is $6\times13824=82944$; and 8×82944, gives 663552 seeds, as the annual produce of one seed, and that so small that 13824 of them are contained in a capsule, whose length is but one ninth of an inch; its diameter but one twenty third of an inch, and its weight but the thirteenth part of a grain. Phil. Trans. N°. 478. sect. 12.

PROPEMPTICON, Προπεμπτικον, in poetry, a poem wherein are expressed ardent wishes and solemn vows for the safety of a person going upon a journey or voyage. Such is that of Horace, L. 1. Od. 3. addressed to Virgil on his setting out for Athens. It was otherwise called *apopempticon*. *Hofm.* Lex Univ. in voc. See APOPEMPTIC, *Cycl.*

The word is derived from προπεμπω, I send forward, or accompany on the way.

PROPHECY *(Cycl.)*—The *prophecies* in the Old Testament, particularly those relating to the Messiah, are allowed by all Christians to have been accomplished in Jesus Christ; but the dispute is, as to the sense or manner wherein they have received their accomplishment.

Opposite systems have been framed on this head; Grotius, Vitringa, Le Clerc, Whiston, Collins, Chandler, &c. Some hold the *prophecies* to have been accomplished in one sense, some in another, and some in both. Mr. Whiston's opinion is mentioned in the Cyclopædia.

A modern learned advocate for Christianity shews, that it was the custom of Jewish writers to say a thing was accomplished when they only made allusions to it, more or less remote; that however there are some formal *prophecies* which literally relate only to the Messiah; other typical *prophecies* which are also to be applied in a literal sense to the Messiah; and that others are only cited as accomplished allegorically, by way of *argumentum ad hominem*, to the Jews only who admitted this way of reasoning *Chandler*'s Defence of Christian. passim. Bibl. Angl. T. 12. p. 458, seq.

Grotius's method is to look for a literal accomplishment in the Jewish affairs about the time when the prophets wrote; or in the affairs of the neighbouring nations with whom they had wars. This method, disapproved by Vitringa and many others, is defended by Le Clerc, Masson, L'Enfant, &c. who even carry it further, so as to maintain that there is no *prophecy* in the Old Testament which has not had a literal accomplishment, and that if there be any wherein this is not known, 'tis thro' the defect of history. Vid. Hist. Crit. Rep. Lett. T. 6. Art. 2. p. 43, seq.

Grotius allows that the *prophecies* applied to the Messiah in the New Testament, tho' they had a literal accomplishment before, had another more sublime and peculiar accomplishment in Christ. This appears from his notes on Matthew and Isaiah, where he says expressly, that what he interprets literally of Jeremiah, agrees in a more sublime manner, and even more literally to Jesus Christ. See also his notes on Psalm XXII. 1. and his Treat. de Veritat. Relig. Christ. l. 5. c. 14. §. 17.

This opinion touching the double sense of *prophecies* is not new. The greatest allegorists, even those among the Jews who make use of this manner of interpreting, have allowed a double sense, as is shewn by Surenhusius; nor does Vitringa himself reject it. In lib. Conciliat. Vid. Bibl. Choif. T. 25. p. 411.

The dispute then between Grotius and his adversaries, is not whether there are two senses in the *prophecies*, but whether several *prophecies* of the Old Testament, which relate to Christ, had a literal, less sublime, and less perfect accomplishment before they were accomplished in Christ. The affirmative is maintained by him, the negative by them. Vid. Le Clerc. Bibl. Choif. T. 27. p. 391, seq.

As to the accomplishment of particular *prophecies*, we find endless disputes among critics and interpreters, concerning those of the conception of a virgin, the seed of a woman, the sceptre's departure from Juda, the root of Jesse, out of Egypt have I called my son, he shall be called a Nazarine, Daniel's seventy weeks, the Babylonish captivity, the dispersion and restoration of the Jews. Few modern events of any considerable note, but one interpreter or other finds to be the accomplishment of some Scripture *prophecy*. The late war and death of the king of France, and numerous others are pretended to be found in Holy Writ.

The visions in the Old and New Testament, have been more tortured for accomplishments than the *prophecies* themselves. Such is the case of Ezechiel's temple, the temporal reign of Christ on earth, the destruction of antichrist, the loosening the great dragon, the opening of the seals, and many others. *L'Enfant* and *Beausobre* Vers. du Nouv. PROPOLIS, *(Cycl.)* a name given by authors to a certain substance more glutinous and tenacious than wax, with which the bees stop up all the holes or cracks in the sides of their hives. Beside the wax and the honey which the bees gather in their daily travels, they have occasion for this third substance at times, and that especially when they are placed in a new hive

They very well know that it is necessary to their well being, that they should be kept perfectly warm in their hives, and strongly defended against the injuries of weather: to keep out wind and rain they stop every little chink in the sides of their habitations with this matter; nor is this the only reason for it, they have other enemies of the insect tribe, which are on different occasions eternally seeking a way into their habitations; some of them feed on their honey, others on the wax, and others on their young offspring. To be guarded against these, they as firmly as possible block up all the accidental holes or cracks in the hive, and guard the principal opening, which serves as the gate of their city, by numbers which are always placed round about it, so that no enemy can come in that way. *Reaumur*'s Hist. of Insects, V. 10. p. 76.

These wary animals not only stop up in this manner all the cracks they can find, but even examine all the weak places of the hive, and will eat away a rotten or too weak part, and make up the deficiency with this *propolis*. This was elegantly seen in the case of some of Mr. Reaumur's glass hives, which were framed of wood, and had squares of glass in the proper places: these squares of glass were fastened in with slips of pasted paper. The bees finding this a much weaker part of the hive than any other, and capable of being eaten thro' by their enemies, soon gnawed to pieces all the paper and paste, and covered those parts with the *propolis* in the place of that matter.

It might seem that the bees might use wax on this occasion; but this would be no defence against those of their enemies, which devour and feed on wax; and nature has guarded them against these, by supplying them with a matter which spreads more easily, is of greater tenacity, and fixes itself much more strongly in the small crevices than wax could do It has been known from the earliest times, that the bees made use of this substance; Pliny mentions it, and tells us, that the authors of his time distinguished three kinds of it, the first they called *metys*, the second *pissoceron*, and the third *propolis*. The last of these names is only retained among the later writers, and seems to have stood with the antients for the pure substance, the other kinds differing from it only as they were more or less mixed with wax.

The *propolis* itself is a substance perfectly different from wax; it is found to be soluble in spirit of wine, or in oil of turpentine; and is soft when laid on by the bees, but grows hard afterwards; it may, however, even in its hardest state, be softened by heat. By all these observations it appears very plainly, that the *propolis* is a true genuine vegetable resin, of the nature of many others which we have in common use.

The authors who have treated of this substance, have described it very differently; George Pictorius, who has written of bees, says, that it is of a yellow colour and an agreeable smell, like that of storax, and that it would spread when warmed properly. Pliny and the old authors describe it as being of a rank and strong smell, and being used as a succedaneum for galbanum; and at present we usually find it of an aromatic and agreeable smell, insomuch that some rank it among the perfumes. The apothecaries, in some places, keep it as a medicine in their shops; but it is to be observed, that it is very various in its nature; for according to the descriptions of authors, it is sometimes sweet and sometimes stinking. The truth is, that the bees who collect it as a thing to be used for a cement, not for food, are not over curious of what plants they gather it from; and hence in different hives it is found of very different colours and consistences.

In general, the *propolis* is of a brownish red colour on the surface; the red sometimes predominating, sometimes the brown; but when broken it is yellowish, or approaching to the

the colour of wax. It very readily diffolves in fpirit of wine or oil of turpentine, and this folution is of a fine gold colour, and will ferve extremely well as a varnifh to colour filvered picture-frames, or other the like work, into the appearance of gold. It gives a fine gold-like appearance, indeed, to any white metal of a polifhed furface; all that it wants is a little more brilliancy, which is eafily given it by mixing a fmall quantity of maftich, or of fandarach in the folution. *Reaumur's* Hift. Inf. Vol. X. p. 77.

The bees having much lefs frequent occafion for this fubftance than for wax, are very feldom to be met loaded with it; they never bring any of it home, except when they are eftablifhed in a new hive, or when there happens fome crack or flaw in an old one. The morning is the time of their gathering the matter of which they make their wax; but the evening is the time of their going out for the *propolis*. When there is occafion for this fubftance in the hive, the bees will be found to return loaded with it in lumps placed upon the third joint of their hinder legs, in the very fame manner in which they carry their wax. It differs greatly from the rough wax which they carry, as that is made up of fmall round or oval granules; and this is one uniform fubftance of the nature of a foft refin or gum. This fubftance is not to be eaten firft, in the manner of the rough wax, in order to its being rendered fit for ufe; but is of immediate readinefs for fervice. It is one of the moft troublefome offices of the bees, to bring it home and apply it to the places where it is wanted. It is fo tough and vifcous, that it muft be with infinite difficulty that the poor bee gets it upon her leg; but the getting it off again, is a tafk left to others. As foon as one of the fwarm enters the hive loaded with this, feveral others immediately gather about her, and bite out pieces of a very minute fize from the lumps fhe is loaded with. This is a work of great trouble and difficulty for them; for their teeth are fo faftened in by the tenacity of the matter, that it is with the utmoft labour that they get off the little portion they have thus feized upon. This piece draws out, in the pulling it away, into a long thread, as any of the foft gum-refins would do. Often the matter is fo tenacious, that the bee which feizes on it, in order to feparate a piece, is not able to do it; but remains hung faft by the teeth to the leg of the other. Often two bees are at work at a time, one at the lump of *propolis* attached to each leg of the bee that brought it in: as foon as they have any of them diflodged a piece, tho' ever fo fmall, they immediately fly with it to fome place where there is a crack to be ftopped, and the moment thefe are gone, others fupply their place at the lumps; fo that both legs of the bee who brought in the load are very foon perfectly cleared of it, when the whole is employed to the proper purpofe. The great trouble of working and feparating this matter, and the fmall quantity that one bee is able to bring at a time, might feem to prove, that it would be an endlefs work to ftop the large holes fometimes found in the hives with it: but the great number of bees employed in this work at the fame time, are what makes it go off tolerably well, tho' each has unqueftionably a very hard tafk to perform in it.

It is the general opinion of thofe who have ftudied bees, that the willow and the poplar are the trees which principally furnifh them with this refin, which, when it has paffed through their management, we call *propolis*. It is very certain, however, that thefe are not the only trees which afford it, fince the bees are not found to want this neceffary material for their work, in places where there are no trees of that kind in the neighbourhood of the hives. *Reaumur's* Hift. Inf. Vol. X. p. 80.

Mr. Reaumur was very defirous of feeing the manner in which the bees collected this tenacious matter; but watched them in vain in the fields and upon the trees: although an accident gave him an opportunity of obferving them at their work on this occafion. He had taken off the cover of one of his glafs hives on fome occafion, and as there was much of the *propolis* fticking to its edges, which the bees had ufed to ftop the crevices when it was fixed in, the bees of a neighbouring hive foon found that here was this fubftance ready for them in large quantities together, and that they could have it at a very eafy rate: they therefore immediately detached a party to bring it off; and in confequence of this, it was eafy to obferve any one of them, during the whole courfe of his work. The manner of feparating it from the fubftance it lay upon, was by detaching very fmall pieces at a time with the teeth; thefe, when they had been with great labour loofened from the reft, were delivered to the foot of one of the fore-legs: they were here moulded into a roundifh lump, and, after a little working, delivered to the foot of a fecond leg; and finally, by this to the flat triangular piece which makes the third joint of the hinder legs, the part deftined in their common labours to receive the lumps of rough wax. It is here preffed down with fome violence, and afterwards fixed in its place by three or four ftrokes from the fame foot; and then another is feparated by the teeth in the fame manner, and by the fame means carried to the fame place, and added to the firft piece; and fo on till the whole work is finifhed. The bees which found this treafure loaded themfelves to an immenfe degree, carrying of a lump larger than a pea on each leg, and the time to take up thefe large parcels was at leaft half an hour: after carrying this load to the hive, and being relieved from it by the joint labours of feveral others, the bee which has been at all the pains of collecting it, joins a clufter of others in fome quiet part of the hive, where it refts for the remainder of that day.

The *propolis* is not only ufed by thefe animals for ftopping up holes and cracks in the fides of their hives; they often cover with it the furface of thofe crofs pieces which fupport the combs, and when they can find it in fufficient plenty, they cover over the whole inner furface of the hive with it, to defend it from the entrance of enemies of any kind which might eat their way through the fhell of the hive. The antients who obferved this lining of the hives, fuppofed that the bees ufed the *propolis* to faften their combs to the hive; but later obfervation has proved this to be an erroneous opinion, the combs being always faftened with lumps of wax only.

Befides the ufes of the *propolis* already mentioned, there is another very fingular one, which muft by no means be paffed over in filence: this is the embalming and preferving, by means of it, certain bodies which they know not to difpofe of otherwife. Notwithftanding the care that the bees take to guard the entrances of their hives, enemies of one kind or other will often get in: thefe ufually fare very ill; for the bees fting is a weapon very capable of punifhing fuch an intrufion, and the fwarm is fo numerous, that it is not eafy for the intruder to efcape repeated wounds. When a creature of fmall fize has thus entered, and thus been killed for it, the bees with great care and pains carry him out; for they will bear no fort of foulnefs in the hive. It fometimes happens, however, that an unlucky fnail, particularly of the large naked kind, crawls into the hive; in this cafe he never ceafes crawling over the combs fo long as he lives. It is no wonder that fo cleanly creatures as the bees are highly enraged at this nafty vifiter: they foon furround and kill him with their ftings; but then as he is a load too heavy to allow a poffibility of their carrying him out, they prevent the mifchiefs attending the ftinking of the carcafe, by covering it over with a thick coat of this *propolis*, which perfectly well preferves it from putrefaction. *Reaumur's* Hift. Inf. Vol. X. p. 84.

The common garden fnail, with the fhell, fometimes alfo vifit thefe induftrious and cleanly animals, and this creature they fecure in a different manner, and that at the expence of only a very fmall quantity of the *propolis*: but Reaumur had an opportunity of obferving their method of deftroying this enemy in a very accurate and eafy manner, in one of his glafs hives. The fnail had entered the hive early in the morning, and after crawling about for fome time, had fixed itfelf to one of the glafs fquares by the fame glutinous matter by means of which it is frequently found fixed to old walls and trees; when the bees found their enemy thus fixed, they furrounded him, and in a few minutes formed a border of *propolis* round the verge of the mouth of the fhell: this they continually added more and more to, till they had formed fo thick a coat round it, that the fnail could never move from the place again.

The fnail is eafily able to loofen the faftening which it gives itfelf to any place, becaufe this is done by means of a gum, which water will diffolve; therefore the firft fhower of rain, or the moifture which the animal is able to fecrete from its own body, releafes it in this cafe; but the faftening which the bees ufe to fix the fhell to the glafs being a refin, this remains untouched by water, and muft keep the animal fixed in its place till death, and even long afterwards.

It feems probable, that the bees are not over curious in the choice of the matter of the *propolis*; but that many vegetable refins indifferently ferve for this purpofe: it has been tried, however, whether they would ufe common turpentine, and fome other of the refins in ufe among us, by laying them before their hives; but without fuccefs. This is an experiment, however, that requires frequent repetition; fince there are many feafons at which the bee has no occafion for this matter. *Reaumur's* Hift. Inf. Vol. X. p. 80.

PROPOMA, a name given by the antients to a potion prepared of honey and wine boiled together: the proportions were four parts of wine to one of honey.

PROPTOSIS, in furgery, a name by which fome authors have called that diftemperature of the eye commonly called a *prolapfus oculi*. *Heifter's* Surg. p. 427. See PROLAPSUS *oculi*.

PROSCHÆRETERIA, Προσχαιρητήρια, in antiquity, a day of rejoicing, kept when a new-married wife went to cohabit with her hufband. *Potter*, Archæol. Grec. T. I. p 427.

PROSCLYSMA, a word ufed to exprefs an irroration, or fprinkling of any part with a fluid, as the throwing water in the face in cafes of fainting, &c.

PROSECUTION. To make men liable to criminal *profecutions* by the law of England, it is required that they have the ufe of reafon, and that they be *fui juris*. On the firft account the law indulges infants under the age of difcretion, ideots, and lunatics, whatever the nature of the fact may be; and even againft the perfon of the king, as it has been held of late: neither will it fuffer one who becomes *non compos*, after he has committed a capital offence, to be either arraigned or executed. See LUNATIC and INFANT, *Cycl.*

As to an offender's being *sui juris*, it is to be obferved, that neither a fon, nor a fervant, nor any other perfon, except a feme covert, is excufed on the account of acting by command or coercion of another. *Hawk.* P. C. B. 1. c. 1. See the article FEME *covert*.

PROSERPINA, in botany, a name given by fome authors to chamemile *Ger.* Emac. Ind. 2.

PROSEUCHE, in antiquity, properly fignifies prayer; but it is taken for the places of prayer of the Jews, and was pretty near the fame as their fynagogues. But the fynagogues were originally in the cities, and were covered places; whereas, for the moft part, the *profeuches* were out of the cities, and upon the banks of rivers, having no covering, except, perhaps, the fhade of fome trees, or fome covered galleries. *Calmet.* Diction. Bibl.

The word is Greek, Προσευχη petitio, precatio, oratio. Vid *Hederic* Lex. Man. Græc. in voc. Juv. Sat. 3 v. 296. In qua te quæro *profeuchâ*.

PROSLAMBANOMENOS, in the antient Greek mufic, was the firft note of their fcale, whether afcending or defcending. Phil. Tranf. N°. 481. p. 269.

It was ufual among the Greeks to confider a defcending as well as an afcending fcale; the former proceeding from acute to grave precifely by the fame intervals as the latter did from grave to acute. The not diftinguifhing thefe two fcales has led feveral learned moderns to fuppofe, that the Greeks, in fome centuries took the *proflambanomenos* to be the loweft note in their fyftem; and in other centuries to be the higheft. But the truth of the matter is, that the *proflambanomenos* was the loweft or higheft note, according as they confidered the afcending or defcending fcale [a]. The learned author of this remark [b], thinks this diftinction of the afcending or defcending fcales conducive to the variety and perfection of melody; but he fays, he never met with above one piece of mufic, where the compofer appeared to have any intelligence of that kind: and this piece was above 150 years old. [[a] Phil. Tranf. ibid. [b] Dr. *Pepufh*, ibid.]

The *proflambanomenos* was one of thofe founds which the antients called *ftabiles*, from their remaining fixed throughout all the genera and fpecies. Phil. Tranf. N°. 481. p. 270.

PROSODIA, Προσωδία, in antiquity, a facred fong, or hymn, fung in honour of the gods. It differed from the *profodia* with an omega, προσωδία, which was a fong fung in concert with fome mufical inftrument. Mem. Acad. Infcript. Vol. 14. p. 352.

PROSTATES, Προστάτες, among the Athenians, was ufed to fignify any patron to whofe protection fojourners in that city committed themfelves.

He was allowed to demand feveral fervices of them, in which, if they failed, or neglected to choofe a patron, an action was commenced againft them before the polemarchus, and their goods were confifcated. *Potter*, Archæol. Græc. l. 1. c. 10. T. 1. p. 56. See SOJOURNERS.

PROSTYPA, Πρόστυπα, in the fculpture of the antients, images carved in fuch a manner as to be only half raifed above the ground, or plain, on which they were formed.

They feem to adhere to it, and have only one fide expofed to view. To *proftypæ* is oppofed *ectypa*. *Hoffm.* Lex. in voc. See ECTYPA.

PROTEA, in the Linnæan fyftem of botany, a genus of plants which takes in the lepidocarpodendron, and the hypophyllocarpodendron of Boerhaave.

The characters of this are, that the calyx is a common perianthium, containing feveral flowers; it is made up of feveral little leaves laid in a loofe manner over one another, and the inner ones very long, expanded, coloured, and remaining when the flowers are fallen. The flower is monopetalous, or made of one leaf, in form of a fimple tube, divided at its fummit into four fegments, each as long as the tubular part, and all ftrait, obtufe, and bent backward. The ftamina are four extremely fhort filaments, inferted on the fegments of the flower, near its fummit; the antheræ are laid clofely on thefe. The germen of the piftil is below the proper receptacle of the flower. The ftyle is flender and very long, and the ftigma fimple. The fruit is one common large receptacle, which is flat and divided by hairy fcales. The feeds are fingle. *Linnæi* Gen. Plant. p 22.

PROTELARII, among the Romans, were the poorer fort of citizens, whofe eftate did not exceed fifteen hundred pieces of filver. They were diftinguifhed from thofe who were worth little or nothing; thefe laft being called *capite cenfi*. *Pitifc.* in voc. See CAPITE *cenfi*.

PROTHESIS, Πρόθεσις, among the Greeks, the ceremony of laying the dead near the door till the time of their interment, with their feet outwards; on which account the Romans called them *pofiti*. *Hofm.* Lex. in voc. See POSITI.

The word is derived from προτίθημι, *I expofe to view*.

PROTIPULA, in natural hiftory, a name given to a fpecies of fly refembling the tipula, or long-legs, in many refpects; but differing in regard to the effential character, which, in the tipula, is the having two beards growing on the anterior part of the head, and occafionally falling over the mouth, and clofing its aperture; thefe the *protipula* wants. See the article TIPULA.

PROTOGALA, the term ufed by the antients for what we call *beeftings*, the firft milk of a cow or other animal after her having brought forth young.

PROTOMEDIA, in botany, a name given by fome authors to the pimpinella or burnet. *Ger.* Emac. Ind. 2.

PROTOPASCHITÆ, Πρωτοπασχῖται, in church hiftory, Heretics, who after the manner of the Jews, celebrated the feaft of Eafter with unleavened bread. They were likewife called *Sabatiani*. *Hoffm.* Lex. univ. in voc. See SABATIANI.

PROTRUSORIS *ordo exterior*, in anatomy, a name given by Santorini to certain fafciculi of the great zygomatic mufcle, running under the flefhy part of the lower lip. See the articles ZYGOMATICUS *major*, and LABIORUM *attollens*.

PROTRUSORIS *interior ordo*, in anatomy, a name given by Santorini to a mufcle of the face, called by Albinus *orbicularis oris*; and by Cowper and Douglafs *conftrictor labiorum* and *fphincter labiorum*.

PROTRYGIA, Προτρύγια, in antiquity, a feftival in honour of Neptune, and of Bacchus, furnamed Προτρύγης, or Προτρύγαιος, ἀπὸ τῆς τρυγός, *i. e.* from new wine. *Potter*, Archæol. Græc. l 2. c 20. T. 1. p. 427.

PROVER, (*Cycl*) among jewellers, an inftrument by which they examine the fize and depth of diamonds It is a fpring in fhape not unlike a pair of caliber compaffes, kept at the proper diftance by means of a fpring. *Jeffreys* on diamonds, p. 18, and plate 6.

PROX, in natural hiftory, a name given by Ariftotle to the *cervus platyceros*, or broad-horned ftag The modern Greeks have called it *platonia*, and the interpreters of the oldeft writers have rendered the word by *dama*; but this we are to underftand as meant of the dama of our times, for the dama of the antients was our ifarus, or farius, a kind of goat, whofe fkin affords us the true chamoy leather. This has no title to the name platonia, or the platyceros; nor is the creature that Ariftotle defcribes under the name *prox*, nor of the ftag kind, as that certainly was.

PRUNELLA, or BRUNELLA, in botany, the name of a genus of plants, the characters of which are thefe: the flowers confift of one leaf, which is of the labiated kind. The upper lip is galeated, and the lower is divided into three fegments, the middle one being hollowed like a fpoon. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and furrounded by four embryos, which afterwards become four feeds, ripening in an open capfule which was the cup of the flower.

To thefe characters it may be added, that the ftamina have not that refemblance of the os hyoides that thofe of fage, clary, and the reft have; and that the flowers are always arranged in clofe fpikes. See Tab. 1. of Botany, Clafs 4.

The fpecies of *prunella*, enumerated by Mr. Tournefort, are thefe: 1. The broad-leaved Italian *brunella*, with flefh-coloured flowers. 2. The common blue-flowered *brunella*, with undivided leaves. 3. The common *brunella*, with undivided leaves and purple flowers. 4. The common *brunella*, with undivided leaves and white flowers. 5. The great flowered *brunella*, with blue flowers. 6 The great flowered *brunella*, with flefh coloured flowers. 7. The great flowered *brunella*, with white flowers. 8. The greateft Pyrenean *brunella*, with very large flowers. 9 The Portugal *prunella*, with a larger flower and fpike. 10. The narrow-leaved, or hyffop-leaved *brunella*. 11. The *brunello* with diffected leaves. 12. The cut-leaved *brunella*, with white flowers. 13. The leaft white-flowered cut-leaved *brunella*. 14. The cut-leaved *brunella*, with rofe-coloured flowers. *Tourn.* Inft. p. 182.

PRUNUS, the *plum*, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the rofaceous kind, being compofed of feveral petals, arranged in a circular form. From the cup of the flower there arifes a piftil, which finally becomes a fruit of a roundifh or oval figure. This is foft and flefhy, and includes a ftone pointed at each end, within which is the kernel. *Tourn.* Inft. p. 622.

The fpecies of *plum* enumerated by Mr. Tournefort, are thefe: 1. The double-flowered *plum* tree. 2. The *plum* with large, fweet, bluifh black fruit. 3. The *plum* with fmall fweet, bluifh black fruit. 4. The *plum* with large flefhy and fowerifh fruit. 5. The *plum* with oblong blue fruit. 6. The *plum* with hard black fruit. 7. The *plum* with very large bluifh-red, fweet, and fugar-like fruit. 8. The *plum* with the large, bluifh red, late ripening fruit, called by the French the *imperatrice*. 9. The *plum* with large, oval, red fruit, called the *red imperial plum*. 10. The *plum* with a large, oval, yellow fruit, called fimply the *imperial plum* 11. The *plum* with a very large, oval, yellow fruit. 12. The wax-coloured *plum*. 13. The *plum* with large, round, red fruit. 14. The *plum* with a large, round, yellow, fweet-tafted fruit. 15. The almond *plum*. 16. The *plum* with oblong, white, acid fruit 17. The fweet-tafted Brignole *plum*. 18. The *plum* with a remarkably red and fweet fruit. 19 The *plum* with large, round, blackifh, and very fweet fruit. 20. The *plum* with fmall, round, blackifh, and very fweet fruit 21. The *plum* with a fmall auftere fruit. 22. The *plum* with fmall and early ripe fruit. 23. The *plum* with fmall, yellowifh green fruit. 24. The common wild *plum*. 25. The tall,

early ripe, wild *plum*. 26. The wild *plum*, with large white fruit. 27. The wild *plum*, with red, harsh, and unpleasant fruit, called in England the *hedge-plum*, or *horse-plum*. *Tourn.* Inst. p. 612. See PLUM.

PRUSSIAN *blue*. In a paper of Dr. Woodward's, communicated to the royal society from another hand, there is given a short way of making the *Prussian blue*, which when tried over again by Mr. Brown the chemist, was found to answer perfectly well; and gave hints and occasions to several experiments which gave great light into the true nature of the bodies used in that preparation.

The method was this: four ounces of blood dried, and four ounces of salt of tartar were calcined together; two hours after which, a black spungy substance remained in the crucible, weighing four ounces; a solution of which being made in rain water, and afterwards filtered, left a remainder which when dried weighed nine drachms. An ounce of English vitriol was dissolved in six ounces of rain water, and eight ounces of crude alum in two quarts of water. These being mixed hot with the blood, became green; and on adding two or three ounces of spirit of salt, they became of a fine blue, which will subside, and leave the water clear at top. Mr. Brown found the process exactly answer, and the product was an ounce of a very fine colour, and perfectly fit for the painter's use.

Among the several experiments which were made by mixing, in different manners and proportions, the several liquors of which this colour was to be prepared, all produced a blue; but that in different degrees, some being deeper, and others much paler. In one experiment the alum was wholly left out, and a very pale blue was produced; in another, the alum and vitriol were used in equal quantities, and then the product was an extremely deep blue.

Upon the whole, the prescription seems given after repeated trials, and appears to be that very combination of the several ingredients, which must give the very finest colour they are capable of giving.

It would be curious to know what gave the first hint for the production of so fine a colour from a combination of such materials, especially when we come to consider, that the blood has the principal share in this surprising change. Blood of any kind, or flesh of any kind, would produce the same effects; but it is probable that flesh would not yield so strong or fine a colour. Beef has been tried, and found to yield a *blue*, but not so fine as the blood. Phil. Trans. N°. 381. p. 17.

The solution of alum, mixed with that of vitriol, produces no change of colour. If to these the spirit of salt is added, there is still no change; but as soon as ever the blood is added, the blue is produced. If instead of the lixivium with blood, there be added to these ingredients, a lixivium with salt of tartar only, there follows a precipitation, indeed, but of no colour; and when the spirit of salt is added to this, it clears up, and the precipitation is received again into the liquor.

The very same effect will follow if any volatile alkaline spirit is made use of as a precipitant, or any volatile salt dissolved in water; nor can the blood itself be supposed to communicate this change from any such properties, the heat of the fire it undergoes in calcination being sufficient to drive them off. In the calcination of the dried blood and salt of tartar it was observed, that there was a loss of just one half. It is difficult to determine with certainty, what quantity of either was lost in this operation; but it will easily be granted, that a much greater quantity of blood was lost than of the salt: and this is confirmed by experiment; for the same quantity of salt of tartar, calcined alone in the same heat, has been found to lose only one eighth part; whereas, when dried blood was calcined by itself, it lost more than six eighths. It appears that the blood in calcination parts with its tinging quality to the salt, or that quality is extracted from it by the salt, and passes with it in its dissolution with the boiling water.

To prove this, some dried blood was calcined alone, and a strong decoction of it made in water, and afterwards filtered: this, when mixed with the former solutions, produced little or no alteration; and on the addition of the spirit of salt, the whole became of an amber colour, without any precipitation. When this, mixed with oleum tartari, was added to the former solutions, it caused a precipitation, but no colour; and the spirit of salt being added to the liquor, made it clear again; but of no other colour than the amber tinge it had before.

The change of colour is not effected in any of the materials, except in that of the solution of the vitriol; so that the alum seems only to be of use in fixing the colour, as it is often used by dyers to that purpose: and the spiritus salis gives it a deeper dye; for if the lixivium with blood be poured to a solution of alum alone, there will fall a sediment a little inclining to the purple; which on adding some spirit of salt, changes to a brown. Much the same changes will also be produced if you pour the spiritus salis to the lixivium; but not the least appearance of *blue*: but when the lixivium is poured to a solution of vitriol, there is immediately a deep *blue* produced, and this is still heightened by the spirit of salt.

In all the recipes which have been given for making the *Prussian blue*, the liquors are ordered to be mixed together boiling hot, except the spirit of salt; and experience shews, that the colour is most readily and beautifully made that way: but in experiments made with all the liquors cold, the colours have been very well produced, only in less beauty; and they have required washing several times in fresh water, to bring them to their beauty.

If after the lixivium has precipitated the *blue* colour, on mixing with the solutions of alum and vitriol, a little more of the blood lixivium be added afterwards, the whole loses its *blue*, and becomes brown; but on adding some more spirit of salt, the matter becomes of a fine *blue* again.

As it appears from some of the before mentioned experiments, that the solution of vitriol is the only thing which makes the colour with the blood; and as this vitriol is no other than iron dissolved by a liquor running from the pyrites when long exposed to the weather, it should seem that the iron was the only substance that really produced the colour: and experiments confirm this to be the case. Phil. Trans. N°. 381. p. 20. See the article BLOOD.

PRYTANITIDES, in antiquity, a name given to those widows who at Athens, and throughout all Greece, had the sacred fire of Vesta committed to their care. The custom of the Greeks, in this respect, differed very much from that of the Romans; who allowed none but virgins to tend this sacred fire, whence they were called *vestals*. See VESTALS, *Cycl.*

They had the appellation of *prytanitides* from Πρυτανειον, a name common to all places sacred to Vesta. *Hoffm.* Lex. univ. in voc.

PSALMIST, in the church of Rome, one of the lesser ecclesiastical order, the same with what among us is called *clerk*, *precentor*, or *singer*. *Hoffm.* Lex. in voc.

PSEGMA, a name given by some of the antients to the flos æris, or flowers of brass.

PSELAPHIA, a word used by the antient medical writers to express friction with the hands, in cases where the distempered parts required it. This was always esteemed a part of the business of a physician, and was done with his own hand.

PSEN, Ψην, the name given by naturalists to the fig-gnat, a small species of gnat bred in figs while growing on the tree, and always remaining on the leaves of the same tree, and feeding on its juices. See CAPRIFICATION.

PSEPHISMA, Ψηφισμα, among the Athenians, a decree of the senate; the same with *probuleuma*. See PROBULEUMA.

PSEPHOMANTIA, Ψηφομαντεια, in antiquity, a species of divination, the same with *cleromancy*. See CLEROMANCY, *Cycl.*

PSEPHOPHORIA, in antiquity, the art of using the *psephi*, Ψηφοι, or counters. This was the first arithmetic taught children of every condition. Capitolinus, in his life of Pertinax, says, *Puer literis elementariis & calculo imbutus*. Those who taught this art were called *calculones*, if slaves, or lately made free; but those of better condition were called *calculatores* and *numerarii*. Every family, anywise considerable, had one of these masters, the title of whose charge was *a calculis*, *a rationibus*. See the next article.

PSEPHOS, Ψηφος, in antiquity, a name given to several things, as small stones, shells, and beans, used among the Greeks in giving their suffrages, and in their computations. Their origin is, by Mr. Mahudel, ascribed to the sons of Noah, who used this kind of calculation to assist their memory in numbering their flocks. Josephus assures us, that the Egyptians borrowed this method of counting from Abraham; and Herodotus relates, that these small stones were used both by the Egyptians and Greeks, only with this difference, that the latter placed them and cyphers from left to right, and the former from the right to the left. The art of using them in calculations was called *psephophoria*. See PSEPHOPHORIA.

Psephi were in use too among the Romans, who called them *calculi*. Whatever materials they consisted of, they were all of the same colour when used in calculations; whereas those used in giving suffrages were partly black and partly white. Lucky days were denoted by white, and unlucky by black ones. In passing of laws, there were characters engraved on them, as V. R. i. e. *uti rogas*; and A. i. e. *antiquo*. Those marked with V. R. approved, and those with A. rejected the law in question. Judges made use of calculi marked with the letter A. i. e. *absolvo*, when they absolved the accused person; but if they were for condemning him, they used such as were marked with the letter C. i. e. *condemno*: and if the evidence for and against the accused person was equal, so that they could neither condemn nor absolve him, they made use of calculi marked with N. L. i. e. *non liquet*. There was another kind of calculi used at public games, which were marked with figures: thus, if there were twenty athletæ ready to engage, they threw into a silver urn twenty calculi, every two of which were marked with the same figures, from 1 to 10. Then upon drawing, those who got the same numbers were obliged to engage together; on which account they were called *calculi athletici*.

The Greeks and antient Romans made use of very simple materials for their calculi, such as small stones, shells, and beans; and even in the time of the first Roman emperors, it was thought a piece of luxury to use any of ivory. It is questioned whether the Romans ever used any of silver or gold; because the

the paſſage of Petronius, which is the only one that can be alledged for their having done ſo, may be underſtood of the current coin or money, which Trimalcio, in the time of Nero, employed for calculi, *notari rem omnium delicatiſſimam, pro calculis albis aut nigris, aureos argenteoſque habebat denarios* If this is the true meaning of the author, the firſt gold and filver calculi muſt have been made in France, in the fourteenth century, under Charles VIIth. whoſe name, together with the arms of France, is found inſcribed on the oldeſt ſilver counters in that king's cabinet.

PSETA, in ichthyology, a name given by Athenæus to the fiſh we call the *plaiſe*, the *paſſer lævis* and *plateſſa* of authors. See the articles PASSER and PLEURONECTES.

PSETITES, in natural hiſtory, a name given by authors to a ſtone, having in it the figure of a turbot. There are ſtones found in ſome parts of Germany having the impreſſions of ſeveral kinds of fiſh as perfect as if drawn by a pencil, and it is not to be doubted, but that they in reality owe them to the fiſh themſelves; which at ſome time, perhaps while the earth was overflowed at the univerſal deluge, were received into beds of the matter of ſtone, yet unhardened, which taking its conſiſtence while they were in it, muſt cruſh them, and retain the marks of their bodies. They are uſually found in a whitiſh ſlaty ſtone.

PSEUDO-ACACIA, *baſtard acacia*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the papilionaceous kind, and from its cup there ariſes a piſtil, ſurrounded by a fimbriated membrane. This finally becomes a flat pod, which burſts into two parts, and contains kidney-ſhaped ſeeds. To this it is to be added, that the leaves are placed in ſeries over againſt one another, on a middle rib, the end of which is terminated by a pod leaf.

The ſpecies of *pſeudo-acacia*, enumerated by Mr. Tournefort, are theſe: 1. The common prickly *pſeudo-acacia*, called the *common acacia*, and by ſome the *lotus tree*. 2. The broad-leaved American *pſeudo-acacia*, with roſe-coloured flowers. And, 3. The aſh-leaved American *pſeudo-acacia*, with violet-coloured flowers. *Tourn.* Inſt. p. 649.

PSEUDO-APIOS, in botany, a name given by ſome authors to the roots of the *bulbocaſtanum*, or earth-nut.

The peaſants in Burgundy, and other parts of France, turn up theſe in great quantities with the plough, and eat them. They call them *arnottas*, and ſome of the writers of the adjacent places, not diſtinguiſhing what they truly were, have avoided the common name, by giving them this of *pſeudo-apios*, formed of the name of a root to which they have no alliance, and taking away a name by which they would have been much better known; *arnotta* being only a corruption of the Dutch name *ertnote*, or earth-nut, a name by which they are called almoſt every where.

PSEUDO-ARGYRON, in mineralogy, a word uſed by the antients in two very different ſenſes; ſome make it the name of what Virgil calls *orichalcum album*, white braſs; and others of a mineral with which the common braſs was made.

It is very evident, from the joint teſtimony of the old Greeks and Romans both, that they had in uſe a kind of white metal made of copper, and they eſteemed it greatly above the yellow, or braſs.

Ariſtotle tells us of this white metal, and gives it great encomiums; he ſays, it was very white and very bright; and that it was made by melting copper together with a certain earth: but this he does not deſcribe, ſo that we are left in the dark as to what it was.

This ſhining white metal might very naturally be called *pſeudo-argyron*, or baſtard-ſilver; but beſide this, there is another native mineral ſubſtance, called by the ſame name by Strabo and others: and this is ſaid by Strabo to be uſed in making copper into braſs. Many authors have been much perplexed in endeavouring to make out what this latter kind of *pſeudo-argyrum* was; ſome have ſuppoſed it the molybdæna, others ſome of the brighter lead-ores, and others the micæ argenteæ, or ſilvery talcs, and ſome the ſilvery mundicks: all theſe might in ſome degree anſwer to the name, as to their outward appearance, but they could none of them have the effect of turning copper into braſs.

We are to look for ſomething that will do this firſt, and then find the reſemblance in the colour to ſilver. We well know, that nothing will turn copper yellow but calamine, which is the ore of zink, or zink itſelf. Zink is a metal that comes neareſt the appearance of ſilver of any other, and is ſometimes found native, and in its proper form. If any of the mines wrought by the antients afforded this native metal, there is no doubt but it was the thing called *pſeudo-argyros*, its colour and qualities all anſwering to the name; but if not, it is probable that no more was meant by the name than the common calamine found in their ſilver mines.

Many of the ores of ſilver are found to be very like the common calamine, and in the ſame mines one might be taken for the other at firſt ſight: this reſemblance might very naturally lead people to call the calamine found there *pſeudo-argyros*, or baſtard-ſilver; and the properties of this being the ſame with thoſe of all other calamine, it cannot but anſwer in the ſame manner in making braſs.

PSEUDO-CARPASUM, in botany, a name given by ſome authors to the plant called by the generality of writers *libanotis*.

This is a plant of a very ſtrong ſmell; and the *carpaſum*, or *carpaſium* of the antients, being a poiſonous gum, and the ſmell of the libanotis approaching to the ſame odour, occaſioned its being called the *baſtard-carpaſum*.

PSEUDO-DICTAMNUS, *baſtard-dittany*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of the labiated kind. The upper lip is of an arched form, and uſually is bifid; and the lower is divided into three ſegments. The cup is of the ſhape of a funnel, and from it there ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower. The four embryos which ſurround this afterwards become four oblong ſeeds, which ripen in the funnel-faſhioned caſe, which was the cup of the flower.

The ſpecies of *pſeudodictamnus*, enumerated by Mr. Tournefort, are theſe: 1. The *pſeudodictamnus*, with cups like thoſe of Molucca. 2. The *pſeudodictamnus*, with curled and wrinkled leaves. 3. The Spaniſh *pſeud dictamnus*, with very large, hoary, and whitiſh leaves. 4. The Spaniſh *pſeudodictamnus*, with very large, hairy, and blackiſh leaves. 5. The Spaniſh *pſeudodictamnus*, with fig-wort-like leaves. 6. The ſcentleſs, verticillated *pſeudodictamnus*. 7. The ſmaller, alpine, verticillated *pſeudodictamnus*. And, 8. The ground ivy-leaved African *pſeudodictamnus*. *Tourn.* Inſt. p. 188.

PSEUDOGELSEMINUM, in botany, a name given by Rivinus to a genus of plants, the ſame with the *bignonia* of authors. *Rivin.* 1. 151.

PSEUDO-*ipecacuanha*, in botany, the name by which ſome authors have called a poiſonous kind of American apocynum, the root of which ſomething reſembles the true *ipecacuanha*, and has ſometimes been unfortunately collected and uſed in its place. *Dale*, Pharm. p. 178.

PSEUDO-*pulex arboreus*, in natural hiſtory, the name of a genus of inſects deſcribed by Mr. Reaumur, and ſomewhat approaching in their form to the *pulex aboreus*; but having their wings covered with a ſquammoſe caſe, which thoſe creatures have not, and having broader and flatter bodies.

Theſe principally live upon the fig-tree and the box; they paſs through a ſort of metamorphoſis into a hopping fly, ſuppoſed by ſome of the nature of a graſs-hopper; but erroneouſly, for that animal has a caſe for its wings, and the other not.

It has not yet been determined by obſervation, whether theſe creatures are oviparous, as moſt other of the known winged inſects, or viviparous, as the *pulex arboreus*. That ſpecies which lives upon the box throws out a ſort of glutinous matter from the anus, with which it faſtens the leaf when curled up: this curled leaf, on being opened, always diſcovers the animal, with a long train of connected globules dragging after it, and forming, as it were, a ſort of tail; but when examined more carefully, this is found only to be a train of excrements ſticking together by means of their glutinous quality, and of a ſweet taſte, like that of manna. Theſe, like the others, are at length changed into a ſort of fly, remarkable for its manner of hopping, like the flea. *Reaumur's* Hiſt. Inſt. T. 1.

PSEUDO-*ſaliva*, in botany, a name by which ſome authors call the *phlomis*.

PSEUDO-*ſantalum*, *baſtard-ſaunders*, a name given by ſome botanical writers to the *lignum Braſilianum*, or Braſil wood. *C. Bauhin* Pin. p. 393.

PSEUDO-*ſenna*, *baſtard-ſena*, in botany, a name uſed by ſome authors for the common *colutea veſicarica*. It is called alſo by ſome *ſena pauperum*. *Boerhaave*, p. 468.

PSEUDO *theca*, in natural hiſtory, the name of a ſpecies of two-winged fly, approaching to the nature of the common waſp, but having no ſting. It has a blackiſh head, with two ſhort antennæ, or horns; large, black, reticulated eyes; a long forked mouth, and prominent ſhoulders. The body is long and ſlender, and conſiſts of many joints. The legs are rough and hairy. It is found about dirty ditches, being bred of a water-worm that loves muddy places.

This is, according to the later diſtinctions in the hiſtory of inſects, properly called a *waſp-fly*. There are bee-flies, as much reſembling the bees as this does the waſp.

PSEUDO-*tinea*, in natural hiſtory, the name of a very remarkable ſpecies of inſect deſcribed by Mr. Reamur, approaching to the nature of the *tinea*, or cloaths-moth, while in the worm-ſtate; but not making themſelves coats of the ſubſtance of leaves, cloath, &c. tho' they form a ſort of caſes for their defence againſt a very terrible enemy.

Theſe creatures are truly of the caterpillar kind, and have, in the manner of any of theſe inſects, ſixteen legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, tho' at the expence of their habitations and the cells of their reſervoirs of honey: ſo that it is no uncommon thing for a ſwarm of bees to be forced to change their place of habitation, and make new combs elſewhere; leaving the old ones to this contemptible victor, whom they know not how to drive out or diſpoſſeſs.

Virgil and Ariſtotle, and all the authors who have written on bees, have complained of this deſtructive animal. It never

eats the honey, but feeds only on the wax; attacking principally those waxy cells where the female bee deposits her eggs for the future progeny.

The bees, who are a match for most other creatures, by means of their stings, would easily destroy these weak creatures, were it not for the impervious armour they are covered with. They form themselves a coat of armour of a double matter; the first, which immediately covers the body, is of a kind of silk of their own spinning; and the outer covering over this is of the bees wax: this is laid considerably thick, and the creature just thrusting out its head to feed, goes on devouring the cells undisturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their stings. He never forsakes his covering, but lengthens and enlarges it as he goes; and gnawing down the sides of the cells in his march, without staying to eat them one by one, the havock and destruction he occasions are scarce to be conceived. When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nymph state; whence, after a proper time, it comes forth in form of a moth, with granulated horns and a crooked proboscis.

The bees have cunning enough to know their destructive enemy in this new form, and as this is a weak and defencelefs state, they attack and destroy all the moths of this species they can meet with. They seldom are so fortunate, however, as to kill the whole race as soon as produced; and if only one escapes, it is able to lay a foundation of revenge for the death of its brethren. All the flies of the moth kind lay a vast number of eggs, and this is behind-hand with none of them in that particular: the young ones produced from the eggs of one surviving female of this species, are sufficient to destroy many honey-combs; nay, many hives of them. The moth produced by this caterpillar flies but little, yet is very nimble in avoiding danger by running, which it does with great swiftness.

There are a species of these *pseud.-tineæ*, or wax-eating caterpillars, which infest the subterranean hives of wasps, and other creatures which make wax: the manner of living, feeding, and defending themselves from their enemies, is the same in all these species. These last, if they are at any time distressed for food, will eat their own dung; the wax having passed almost unaltered through their bodies, and being still wax, and capable of affording them more nourishment on a second digestion. These species, tho' they naturally live on this soft food, yet if by any accident they meet with harder only, they know how to live upon it; and can eat a way into the covers and leaves of books, and make themselves cases and coverings of the fragments of these substances. The accurate author of these observations describes also a kind of *pseudo-tineæ* which feed on wool, and another that eats leather; both making themselves houses also on the materials they feed on.

There is also another kind, very destructive of corn: these make themselves a covering by fastening together a great number of the grains, and there living and eating in secret. All these creatures, whatever be their food or habitation, finally become *phalenæ*, or moths; and may be distinguished, even in this state, from the other species, by having granulated horns of a remarkable structure, and all of them a proboscis, or trunk, more or less incurvated. *Reaumur*'s Hist. Inf. T. 1.

PSIDIUM, in botany, the name by which Linnæus calls a genus of plants, named *guajava* by Tournefort and others. *Linnæi* Gen. Pl. p. 211. See GUAJAVA.

PSILOCITHARISTA, among the antients, one who plays on the cithara, without singing in concert to it. *Pitisc.* Lex. Ant. in voc.

PSITTACUS, the *parrot*, in the Linnæan system of zoology, makes a particular and distinct genus of birds, of the order of the hawks; the distinguishing characters of which are, that the feet have two toes before and two behind. *Linnæi* Syst. Natur. p. 44.

The *parrot* is a very well-known bird, of which there are several very beautiful species.

Its head is large, and beek and skull extremely hard and strong. It might seem a wonder why nature has destined to this, which is not naturally a bird of prey, but feeds on fruits and vegetable substances, the crooked beak allotted to the hawk and other carnivorous birds; but the reason seems to be, that the *parrot*'s being a heavy bird, and its legs not very fit for service, it climbs up and down trees by the help of this sharp and hooked bill, with which it lays hold of any thing and secures itself, before it stirs a foot; and besides this, it helps itself forward very much, by pulling its body on with this hold.

Of all animals, the *parrot* and crocodile are the only ones which move the upper jaw; all creatures else moving the lower only. As some particular animals beside are fond of particular foods, so the *parrot* loves nothing so much as the seeds of the carthamus, or bastard-saffron; and eats them without any hurt, tho' they are a purge when given to other creatures.

The *parrots* are common both in the East and West Indies: they are a very brisk and lively bird in the warmer countries; but with us lose much of their vigour. They lay two or three eggs in the hollow of a tree.

In all the known *parrots* the nostrils are round and placed very high upon the beak, and very near one another.

Parrots are divided into three kinds: 1. The larger, which are as big as a moderate fowl, called *macaos* and *cocketoons*; these have very long tails. 2. The middle sized ones, commonly called *parrots*, which have short tails, and are a little larger than a pigeon. And, 3. The small ones, which are called *paroquets*, and have long tails, and are not larger than a lark or blackbird. *Ray*'s Ornithol. p. 72.

PSOAS (*Cycl.*)—PSOAS *major*, called also *lumbaris internus*, a long and thick muscle, situated on the abdomen, on the *lumbar* region, adhering to the vertebræ of the loins, from the posterior part of the os ilium to the anterior part near the thigh.

It is fixed above to the last vertebræ of the back, and to all those of the loins; that is, to the lateral parts of the bodies of these vertebræ, and to the roots of their transverse apophyses. The insertions in the bodies of the vertebræ are by a kind of digitations, and are very little tendinous: from thence the muscle runs down laterally over the os ilium, on one side of the iliac muscle; and passes over the ligamentum Fallopii, between the anterior inferior spine of the os ilium, and that eminence which, from its situation, may be called *iliopectinea*. Before it goes out of the abdomen it unites with the iliacus, and afterwards covers the foreside of the head of the os femoris. It is sometimes accompanied by a small muscle, called *psoas parvus*. *Winslow*'s Anatomy, p 204.

PSOAS *parvus*, a long slender muscle lying upon the *psoas major*: it is sometimes wanting; but tho' some have imagined it wanting in one sex more than the other, the conjecture seems without foundation. It is fixed above by a short tendon, sometimes to the last transverse apophysis of the back, or higher; sometimes to the first of the loins, and sometimes to both: from thence it runs down wholly fleshy, and more or less complex on the great *psoas*, in a direction a little oblique; and having reached the middle of the regio lumbaris, it forms a slender flat tendon, which gradually increasing in breadth like a thin aponeurosis, runs over the *psoas major*, and *iliacus internus* at their union; and from thence down to the symphysis of the os pubis and os ilium, and is inserted chiefly in the crista of the os pubis, above the insertion of the pectinæus. *Winslow*'s Anatomy, p. 250.

Beside this *psoas parvus*, there is another, still smaller, between it and the vertebræ.

PSORA, (*Cycl*) in botany, a name by which Aëtius and several others of the later Greek writers have called the *psorice* of the antient Greeks, that is, the *scabiosa* of the Latins, and our common scabious. It has been supposed by some, that the antient Greeks were not acquainted with our scabious; but that is an erroneous opinion, both the description and virtues of the psorice being the same with those of the scabious. See PSORICE.

PSORALIA, in botany, the name of a genus of plants of the leguminous kind, the characters of which are these: the perianthium is one-leaved, and is dotted with a sort of tubercles, and is divided into five acute segments, the under one being twice as long as any of the others. The flower is of the papilionaceous kind, and is composed of five petals. The vexillum is roundish, emarginated, and rises upwards. The alæ are lunulated, obtuse and small. The carina is dipetalous, lunulated, and obtuse. The stamina are diadelphous filaments, and the antheræ are roundish. The germen of the pistil is slender. The stile is pointed, and of the length of the stamina. The stigma is obtuse. The fruit is a pod of the length of the cup; it is of a compressed figure and pointed. The seed is single and kidney-shaped. It is very singular in this plant, that the cup is always dotted with tubercles, and the petals of the flowers are full of coloured veins. *Linnæi* Gen. Pl. p. 358. *Ray*'s Lugd. p. 372

PSORAS, in zoology, a name by which some authors have called a fish of the turdus kind, remarkable for the variety and beauty of its spots, and more usually known by the name *lepros*. *Willughby*'s Hist. Pisc. p. 320. See LEPROS.

PSORIASIS, a peculiar species of itch affecting the scrotum.

PSORICE, or PSORICE-*poa*, a name given by the botanical writers among the antient Greeks to the plant we call *scabiosa*, or *scabious*.

They have so well described this plant, that there is no room to doubt its being our scabious; and they have attributed the same virtues to it, and given it in the same distempers that we do. Yet some botanists of the later ages, having overlooked their descriptions of the *psorice*, have supposed that our scabious was wholly unknown to the antients: and others have thought that the stæbe of those writers was this plant. But this is as erroneous as the former opinion, for the stæbe of the antient Greeks was the name of the phleos, a kind of marshy gnaphalium, or cudweed; and with some, the name of the pheos or hippopheos, called by Dioscorides *hippophaes*, a prickly shrub, growing on the sandy shores of the island of Crete, and used by the fullers in dressing their cloths.

Pelagonius recommends the herb *psorice*, among several other known antiscorbutics, in a compound medicine, intended for the itch, or any other virulent eruption. Aëtius prescribes the same plant under the name of *psora*, and the modern Greeks call it *campiusa* or *scampiusa*; a name which, tho'

Fuch-

Fuchsius confesses he does not understand, yet is plainly no other than a barbarous term formed by these Grecians on the word scabiosa, the Latin name of the plant.

The change between scabiosa and scampiusa is scarce any thing, for the common custom of the Greeks of these times, was to change the Roman b into mp, in the words which they adopted from that language. *Pelagonius*, c. 300.

PSOROPHTHALMIA, *(Cycl.)* a name given by the antients to a scorbutic disorder of the eye-lids, very troublesome to the patient, and cured with difficulty.

PSUCHAGOGICA, a word used by the antients to express such medicines as were used in apoplexies and faintings, to recal life.

PSUCHROTROPHON, in the materia medica of the antients, a name given to a plant often recommended, but not perfectly understood as to what species it means. It is the same plant called *cestrum* by the Greeks, and has this first name only because of its growing in moist places; the word being formed of the Greek ψυχρος, moist, and τρεφω, to nourish or cause to grow.

Dioscorides has opened a way to great perplexity, by saying that this is the plant which the Romans in his time called the *betonica*, or *serratula*, and sometimes *rosmarinus*. The Romans seem from this to have been at that time very indeterminate in their names; but by the description it appears clearly, that the rosemary which we know by that name, could not be meant; and the question lying wholly between the betony and serratula, is decided in favour of the latter by the description, which, as it stands in Dioscorides, gives the plant the leaves of the oak. This may seem at first sight not to make much in favour of the serratula; but the resemblance is explained, as this author expressly does, to consist only in their being very deeply sinuated, and finely notched, or serrated, all round. The serratula of our times seems plainly meant as the plant. So that this plant we are to observe, is the cestrum and *pseuchrotrophon* of the Greeks, and the betonica, or vettonica, as well as the serrata of the Romans; and is sometimes called *rosmarinus*. Apuleius seems to perplex the whole affair in a strange manner, by saying, the betonica has leaves like the docks, and very large; but we are to observe, that he mistakes the betonica and britannica for the same plant, and says, that the betonica, or britannica, was called *cestrum*, &c. by the Greeks. The reason of his saying the leaves are like those of the dock, is easily seen after this; for Dioscorides says so of the britannica, and that very justly; it being only the common great water-dock, or hydrolapathum. Pliny has somewhere run into the same error, of giving leaves like the dock to the betonica; but the source of his error is plainly the same. We may observe from this, however, that very little dependence can be had on the accounts these authors give us of plants.

PSYCHROLUSIA, a word used by medical writers to express cold bathing.

PSYCTICA, a term used by medical writers to express cooling remedies.

PSYDRACIA, a term used by medical writers to express small tubercles on the head, which resemble pustules, and after a little time corrode and eat through the skin.

PSYGMATA, a name given by physicians to all refrigerating medicines, external and internal.

PSYLLIUM, *fleawort*, in botany, the name of a genus of plants, the flowers and fruit of which are like those of the plantain's, but the stalks are ramose and foliaceous.

The species of *psyllium*, enumerated by authors, are these: 1. The *psyllium* of Dioscorides, or Indian *psyllium*, with jagged leaves. 2. The great upright *psyllium*. 3. The larger procumbent *psyllium*. 4. The lesser *psyllium* of Caspar Bauhine. *Tourn.* Inst. Bot. p. 128.

The seeds of *psyllium* are recommended by many in jaundices and dysenteries; but the present practice receives it only as a mucilaginous feed

PSYLON, in ichthyology, a name given by Aristotle, and many other of the old Greek writers, to the tench, or cyprinus niger. See CYPRINUS and TINCA.

PTARMICA, *sneezewort*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the radiated kind, the disk being composed of floscules, and the outer circle of semi-floscules; these are placed upon the embryo-seeds, and are contained in a squammose cup. The embryos afterwards become slender seeds. To this it is to be added, that the leaves are either only denticulated at the edges, or else divided into large broad segments, wholly different at first inspection from the leaves of yarrow.

The species of *ptarmica*, enumerated by Mr. Tournefort, are these: 1. The common *ptarmica*, with long serrated leaves and white flowers. 2. The common *ptarmica*, with double flowers. 3. The Alpine *ptarmica*, with leaves partly whole, and partly serrated. 4. The low dwarf *ptarmica*, with leaves divided in the manner of those of wormwood. 5. The Cretric shrubby *ptarmica*, with the appearance of the santolina. 6. The purple-flowered tawny-leaved Alpine *ptarmica*. 7. The yellow-flowered sweet scented *ptarmica*. 8. The yellow sweet *ptarmica*, with long and thick tufts of flowers. 9. The Alpine *ptarmica*, with deeply divided leaves. 10. The feverfew-leaved Alpine *ptarmica*. 11. The tall Alpine *ptarmica*, with yellowish white flowers. 12. The other Alpine *ptarmica*, with less compact flowers. 13. The elecampane-leaved Virginian *ptarmica*. *Tourn.* Inst. p. 496.

The common *ptarmica* is frequent in our meadows, and flowers in June and July. The leaves are of an acrid taste, and are sometimes added to sallad instead of cresses, or the garden-tarragon. When dried and rubbed to powder, they are a good sternutatory; they are not over strong, but occasion a continued sneezing, which draws out a great deal of phlegm by the nose. The root has the same virtue more strongly.

PTELEA, in the Linnæan system of botany, the name of a distinct genus of vegetables, the characters of which are these: that the cup is the perianthium, divided into four small segments. The flower is composed of four petals, which are of an oval figure, and pointed at the ends; these are flat, larger than the segments of the calyx, and spread wide open. The stamina are four pointed filaments. The antheræ are roundish. The germen of the pistil is orbicular, but somewhat compressed. The style is short The stigmata are two, and are acute. The fruit is a circular membrane, placed perpendicularly, with a cavity in the middle, which contains the seed, which is single and oblong. The fruit of this genus is extremely like that of the elm, but the stamina are wholly different. *Linnæi*, Gen. Pl p. 49.

PTERIDION, in botany, a name used by some authors for a small kind of fern common in damp places. *Ger.* Emac. Ind. 2.

PTERIS, in botany, the name of a genus of ferns, the characters of which, according to Linnæus, are these: the fructifications are disposed into a line, which surrounds the whole margin of the under part of the leaf. In this disposition the *pteris* evidently differs from all the other capillary plants.

PTEROPHŒNICUS *Indiarum*, in zoology, a name under which Nieremberg has described a bird, which he says is called by the Spaniards there *commendadoza*, remarkable for the redness of the upper part of its wings.

It is of the shape and size of the starling, and not unlike it in colour, but for the singularity of the upper part of their wings, which in one part of their lives are of a yellowish or orange colour, and in the rest red. They are kept in cages and learn to imitate the human voice: they feed on vegetables, principally Indian corn, and are common as well in the colder as in the hotter climates; flying in large flocks, and often doing great damages to the people. They build in trees and are eaten there; but are no very valuable bird. *Ray's* Ornithology, p. 302.

PTEROSPERMADENDRON, in botany, the name of a genus of plants, established by Dr. Amman.

The name is derived from the Greek πτερον, a wing, σπερμα, seed, and δενδρον, a tree, to express a tree with alated seeds.

The characters of the genus are these: the flower is of the rosaceous kind, consisting of several petals arranged in a circular order. From the cup of the flower there arises a pistil, with an embryo fruit, which finally becomes a woody seed-vessel of the shape of a pod, which, when ripe, opens at the end, and is seen to be divided into five cells, containing alated seeds.

Of this genus the author describes two species. The first has leaves like the cork-tree, angulated and hoary underneath, and white flowers: the other has auriculated leaves, and a large flower and fruit The first of these is mentioned in Petiver's museum, N°. 249. under the name of a tree from Champana, with a woody fruit, containing alated seeds: and the other seems to be the tree called *folda*, in the Hortus Malabaricus, Vol. VI. T. 58.

Besides these two species, the author suspects there are four others, which have not yet been sufficiently examined in their various states, to determine whether they are properly of it or not. These are,

1. The poplar-leaved tree alcea, called the *green ebony* at St. Helena, and by the English *blackwood* and *ebony*, Pluk mant. T. 333. 2. The tree alcea, with large red flowers, and with leaves like the black poplar, hoary underneath, called by the English *redwood*, *ejusd.* 3. The quinquecapsular alcea of Florida, with bay-like leaves, lightly crenated, and with alated seeds. And, 4. a tree with pentangular fruit, and alated seeds, collected by Dr. Houston, at La Vera Cruz. Act. Petropol. Vol. VIII. p. 218.

PTERYGIUM, *(Cycl.)* in anatomy and surgery, a preternatural membrane, formed externally upon the coats of the eye, and extending itself over the cornea and pupil, and obstructing the sight. Sometimes this pellicle or membrane appears red, and is then called *pannus*.

It usually arises in the angles of the eyes from the temples toward the nose, and sometimes from above or below, extending itself by degrees over the pupil. Sometimes it only adheres to the cornea by a few slender fibres, and sometimes it is extended over the whole eye, and is every where firmly and intimately attached to it; and in this case the cure is rendered very difficult.

If the patient's constitution, or a beginning inflammation require it, bleeding and blistering are proper in this case; and when the membrane is but thin, gentle escharotics may perform

form a cure, such as burnt alum, vitriol, &c. mixed into a powder with sugar; or a solution of half a scruple of white vitriol in two ounces of celandine or other water.

If these methods prove ineffectual, the assistance of a surgeon must be called in; who seating the patient before him, with his head bent backwards upon his lap, while an assistant holds open the eyelids, takes hold of the thickest or loosest part of the pellicle with a hook, and elevating it a little, passes a threaded needle through it; and taking hold of both ends of the thread, makes a gentle elevation of it; then separates its upper and lower margin with a lancet, that he may afterwards cut off the rest immediately in a strait line near the lachrymal caruncle, with a strait and fine pair of scissars; then he draws back the thread and membrane towards the cornea, and if it adheres any where to the eye, frees it by degrees with the scalpell, or scissars, not wounding the cornea, nor leaving any of the membrane behind to give rise to a new production of it. *Heister*'s Surg. p. 420.

PTERYGOIDÆUS *major* (*Cycl.*)—This muscle lies on the inside of the lower jaw, almost in the same manner that the masseter does on the outside, and is of the same figure with that muscle, only smaller and narrower.

It is fixed above chiefly to the inside of the external ala of the apophysis *pterygoides*. This insertion is wholly fleshy, and from hence it runs down obliquely toward the angle of the lower jaw, and is inserted a little tendinous in the inequalities on the inside thereof, opposite to the insertion of the masseter. *Winslow*'s Anat. p. 253.

PTERYGOIDÆUS *minor*, an oblong small fleshy muscle, situated almost horizontally between the outside of the apophysis *pterygoides*, and the condyloide apophysis of the lower jaw, the subject being considered in an erect posture.

It is fixed by one extremity to the outside and edge of the outer ala of the *pterygoide* apophysis, filling the fossula which is at the basis of this apophysis, near the basis of the temporal apophysis of the sphenoidal bone; from thence it runs backward and a little outward into the void space between the two apophyses of the lower jaw, and is inserted anteriorly in the condyloide apophysis, at a small fossula immediately under the angle of the inner condyle. It is also fixed to the capsular ligament of the joint. *Winslow*'s Anat. p. 253.

PTOSIS, a distemperature of the eyelids, occasioned by a relaxation or tumor of those parts, the same as the phalangosis. *Heister*'s Surg p. 367. See PHALANGOSIS.

PTYALAGOGA, a word used by physicians to express such medicines as promote a copious discharge of the saliva, such as pellitory-root and the like.

PTYSMA, a word used to express whatever is brought up from the lungs by spitting.

PTYSMAGOGA, medicines which promote a copious discharge by spitting.

PUBERTY (*Cycl.*)—Dr. Kramer observes, that all boys at the time of *puberty*, between twelve and fourteen years of age, complain of uneasiness at their breasts, which are swelled and itchy, the nipples and areolæ round them inflaming with pain, and sometimes excoriation and exulceration of some of the lactiferous ducts. The best remedy for which, he says, is to press out the white serum then contained in them, after which they cure with a bit of plaister. Commerc. Norimb. 1735. Hebd. 30. sect. 2.

By the law of Scotland, persons under *puberty*, or under the years of discretion, are capable of committing the higher crimes, which being contrary to the law of nature, are obvious. But they are not chargeable with smaller offences arising from positive law or statute.

PUBIS (*Cycl.*)—The *os pubis* is the least of the three portions of the ossa innominata; the two together form the forepart of the pelvis, and anatomists distinguish in each, the body, the angle, and the branch.

The body of the *os pubis* is its upper part, situated transversely before the inferior part of the os ilium. Its posterior extremity is very thick, and by its union with the ossa ilium forms the oblique eminence which distinguishes these two portions of the ossannominata. It likewise contributes to the formation of the cotyloide cavity. Its anterior extremity ends in a small eminence, or tuberosity, called the *spine* of the *os pubis*, which is sometimes double. The upper edge has on its inner part an oblique ridge, which may be called the *crista* of the *os pubis*, and is continuous with that ridge which distinguishes the margin and the bottom of the pelvis. Before this crista is a broad, oblong, and oblique slope. The lower edge is obliquely notched, and forms the upper part of the foramen ovale.

The angle of the *os pubis* is its anterior portion, and makes part of that connexion called the *symphysis* of the *ossa pubis*. This portion is flat, and not very thick; and in some subjects toward the upper part of the fore-side, near the angular curvature, it has an eminence, which increases the size and extent of the spine already mentioned. The two *ossa pubis* connected together by this portion, form, on the foreside, an unequal convexity; but on the backside a pretty even concavity.

The branch of the *os pubis* is a flat thin apophysis, which running downwards, unites with the branch of the os ischium by a cartilaginous symphysis; of which, however, there remain only some light marks in adults. It compleats the formation of the foramen ovale. The branches of the two *ossa pubis* form, on the foreside, a pointed arch; which, however, in a natural state, is much more round than in a dried skeleton. *Winslow*'s Anatomy, p. 71.

PUCELAGE, (*Cycl.*) in natural history, a name by which some authors among the French have called the porcellane-shells. See the article PORCELLANA.

PUCERON, the name given by naturalists to a small insect of a peculiar nature frequently found on the young branches of trees and plants, and that often in such clusters as wholly to cover them. See Tab. of Insects.

The *puceron* is a small animal, but very numerous in the several genera and species; insomuch, that Reaumur has observed that there is scarce a vegetable to be found, either in the fields or gardens, that has not its peculiar species of *puceron* to feed on its juices. Mr. De la Hire, of the Paris academy, has left many curious particulars in regard to these animals in the memoirs of the year 1703; and Mr. Lewenhoek, and others since, have given figures and descriptions of several of the species.

Pucerons are all viviparous animals, and that after a very singular manner. It is to be observed, that the name is scarce more expressive of the creature, than some of the others given of late to insects; that of the polype to a creature which has no legs or feet at all, is very improper; and that of the *puceron* hardly less so, as it would naturally lead us to imagine, that the creature thus called was able to hop like a flea, whereas, in reality, it is very slow in its motions, and seldom so much as walks.

These creatures have six legs, which are extremely small and slender; and which, when the animal is at its full growth, are loaded with a weight so large, that they seem scarce able to support it. Some of the species arrive at a tolerable bigness for common observation; but the greater number are too small to be accurately seen without the assistance of glasses. Among these insects there are great numbers that in their full perfection have wings, and become a sort of little flies: these are distinguished from the others by the name of *alated pucerons*. *Reaumur*'s Hist. Inf. Vol. VI. p. 9.

Those species which never become winged, have nothing of the appearance of the caterpillar kind; having not long, but short bodies, and much resembling flies whose wings had been taken off. All the species have antennæ or horns; but these in the several kinds are very different from one another, some being very short, and others as remarkably long: and of these last kinds, some carry them strait before the head, as is the usual custom, and others carry them laid along over their backs; in some of these the horns are longer than the body. But beside these antennæ, the greater number of these creatures have two other horns or spines placed in a very singular manner behind them, near the tail. They are placed at some distance at their origin, but they become more distant as they go out from the body. These are much thicker and much shorter than the antennæ; and there are among the various kinds of them, some which actually want them, and others which appear to want them, tho' they have them in reality; and others have in the places of them certain round spots, which stand just where they should, and seem destined to perform their functions.

The several kinds of *pucerons* differ greatly in colour. The greater number of them are green; but many are brown, some yellow, and some are black. In August the rose-trees afford a vast number of them of a pale red, and some exactly of the colour of the damask rose; in some other months of the year we find green ones on the rose-trees. The sycamore and several other plants afford green ones in the summer, and red ones in November; and there seems no doubt, but that these are the same individual animals which change colour, the leaves and juices of the plants being not capable of affording them the same sort of nourishment at some times that they do at others. Some of them also are of a dusky colour, and others bright and shining, as if varnished over. Those of the willow, of the poppy, and some other plants, are of a cloth-like appearance, and some resemble velvet; others, as those of the apricot, and of the catch-fly, are shining as if covered with the finest lacquer. Some appear of the colour of browse metal, when it has its highest polish; such are those of the tansy, and some other plants. The largest kind are found on the oak and other trees. The gooseberry bush affords a species that are of the colour of mother of pearl; and in general, the skin or covering of those species which are thus bright and shining, is much harder and firmer than that of the others. The more usual species are all over of one colour, but there are some others which are spotted; that of the common wormwood is prettily speckled with black and brown; those of the sorrel are green in the middle, and black at each extremity; and there are several others, as of the willow, &c. that are variegated with these two colours.

It is not certain, however, that all the species are peculiar to the plants that they are found upon; for it has been observed, that when a plant of the common wormwood has been full of them, by some accident they have all left it to fix themselves upon plants in the neighbourhood, which had juices of a less disagreeable taste. These creatures always live in companies; we never find them singly on plants, and very seldom other-

wife than in extremely great numbers. In plants they faften themfelves on every part; but in trees, they only feize upon the leaves and young fhoots, and they ufually cover thefe entirely, leaving no part to be feen. *Reaumur's* Hift. Inf. Vol. VI. p. 13.

The elder is the tree on which they are of all others the moft plentifully produced, and on which they are obferved in their feveral ftages with the greateft accuracy and eafe. They often cover the thick green roots of this tree for many inches together, and fometimes for many feet; and they are always placed fo clofe together, that they touch in every part, and fometimes they lie two beds, one over another. Thefe are of a greenifh black. If they are obferved on the branches undifturbed, they are always found to be perfectly quiet, and feem to pafs their whole lives in inaction; but they are all this time doing the moft neceffary bufinefs of life, that is, fucking in their nourifhment from the juices of the tree. They do this by means of a fine flender trunk, which eafily efcapes the naked eye; but is always found by the microfcope, and it is by means of this that they pierce the bark of the tender parts of the vegetables, and get at their juices. The trunk is ufually of two thirds of the length of the body; but when they are moving on, it is always applied fo clofely under the belly, that it is not feen.

When there are two feries of thefe infects placed one over another, they are always more loofly placed in the upper feries, and thefe are ufually the larger and the nimbler in all their motions. In this cafe they have no power of fucking the plant; for befide that it is clofe covered with the other feries, their trunks are not long enough to reach and penetrate it from the heighth at which they ftand above it. Thefe, therefore, are fuch as have no farther need of nourifhment, but are employed in propagating their fpecies. Mr. De la Hire thought, that when thefe animals arrived at their winged ftate, they laid eggs on the ftalks and leaves of thofe plants on which we find them afterwards hatched without wings. The reafon of his fuppofing this, was doubtlefs the opinion of an analogy between thefe creatures, and the butterflies and flies, with the other animals of the winged clafs: but obfervation and facts agree but very ill with that analogy; for if the plants on which they abound be obferved nicely from day to day, their numbers will be found daily to increafe on the leaves and branches, and this without the leaft appearance of eggs: on the other hand, as the new-produced animals are of very different fizes, this fpeaks their being of different ages; and from hence it appears evident, that they are not produced in the manner of other infects, which, when perfect, have wings; but, on the contrary, that they are really produced alive from the parent. Mr. Reaumur faw them brought forth; and, indeed, the obfervations of Mr. Lewenhoek long before, made it evident that this was the cafe; for he faw, by the help of microfcopes, the young animals perfectly formed, tho' extremely minute, in the bodies of the full-grown females.

If the large and full-grown *pucerons* are watched on their native places, with moderately powerful magnifiers, there will foon be feen fome of them that have a fmall greenifh body ftanding out from near the anus. This is the moft plainly vifible in the elder *puceron*, which is itfelf ufually blackifh. This in its firft appearance is an oblong body, refembling an egg flatted a little; but as it more nearly approaches to its delivery from the body of the parent, there appear legs upon it, and it is clearly feen to be a perfect and very lively animal. The legs by degrees fly off from the fides and belly, along which they were laid, and the creature then makes feveral motions to affift the getting out of its head from the body of the parent; for thefe infects are always brought into the world with the hinder part foremoft. The parent is wholly paffive all the time of the birth, all her efforts being internal; fo that the body ftirs not out of its place, nor is the young one able to help itfelf till its whole body is very near out, as the legs are attached to the breaft at a fmall diftance from the head: and even when the head is out, the antennæ require the repeated motion of the young one, for a minute or two, to feparate them.

The whole operation of the delivery of one young one ufually takes up about feven minutes. Mr. Reaumur obferved the delivery of the *pucerons* of all kinds to be in the fame manner. He found it very eafy to make the obfervation, as the female *pucerons* are eafily diftinguifhed from the male by their being much thicker in the body, and by their fkin feeming always much diftended, and by the furrows which feparate the rings of the body being obliterated. They are a fort of animal which propagates fo quickly, that ufually there are many females on the fame leaf or branch of a plant in labour at the fame time; and their fœcundity is fo great, that when they have once begun to bring forth young ones, they feem to continue it inceffantly for a long time together. They will often bring forth fifteen or twenty fucceffively, and if their bodies be a little fqueezed afterwards, there are forced out of it a vaft number of others lefs mature; yet even in thefe the eyes may be diftinguifhed: and after thefe, there follow long chains, as it were, of lefs perfect ones, which feem like the beads of a necklace, and are oblong, and much refemble eggs. Thefe young ones are of different maturity, therefore, in the bodies of the parent; and in that refemble the eggs in hens and other birds, they always growing to a proper ftate for exclufion in this manner, one after another: whereas, in the quadrupeds, which are viviparous, the young ones of the fame brood, if ever fo numerous, always grow to their ftate of maturity for the delivery together, and are all excluded at the fame period. The young *pucerons*, when firft brought forth, are always paler coloured than the parent; but are of the fame fhape and ftructure, except that their bodies are fomewhat flatted.

We fee that they are able to move their legs before they are perfectly excluded from the parent, and as foon as they are fo, they walk and feek a place where they may fix their little trunk into the plant, for the receiving nourifhment. This they always choofe to do as near to fome others of their fpecies as they can, always loving to live in communities. The young one always places its head as near as poffible to the hinder part of the next to it, and thus they continue enlarging their bodies at every new birth. Thofe which live upon the leaves of trees and plants, always fix themfelves on the under fide, being there moft fheltered; and as their number is always very great, they frequently much alter the plant whofe juices they fuck; tho' fome fpecies, both of trees and plants, bear this much better than others. Id. ibid. p. 15.

Thefe little infects are extremely plentiful on many different trees, and are very eafily obferved in their feveral ftages and progreffions by a curious fearcher after them; but if at any time they are not fo eafily found, the perfon who feeks after them may be conducted to them by the ants, which he will find moving in great numbers on the trees and plants where they are, and pointing out the way to them

Mr. Lewenhoek, Hartfoeker, and others, have obferved this, and have fuppofed that the ants fed on them, by their frequenting the places where they are found; but that is far from being the cafe, the ants, on the contrary, feem to love them as friends. Goedart judged better of the matter, and efteemed the ants of great benefit to the nation of *pucerons*, in deftroying many of their bloody enemies. Goedart, however, erred greatly in fuppofing the ants to be the mothers of the *pucerons*; yet this is an error that has place among our gardiners to this day, they all fuppofing that the ants leave a flime behind them, out of which, according to the opinion of this laft author, they judge them to be produced. We may, however, eafily find out the reafon of the ants following the clufters of *pucerons*, without doing them any injury, when we confider that the ants love fugar and all fweet things, and the places about which the *pucerons* are have ufually the cavities filled with a thick faccharine matter, formed of the juices of the plant, extravafated by the wounds they make in it, and dried up to this confiftence by the heat of the fun.

The bladders of the leaves of the elm always contain a large quantity of a faccharine juice; but thofe of the black poplar have always a much fweeter and more delicious fluid in them; and very often on other trees, the extravafated faccharine juice may be feen among the clufters of thefe animals, and the ants crawling over their backs to feed upon it.

This liquor of the elm has not efcaped the obfervation of the fearchers after remedies from the vegetable world; but tho' great virtues have been attributed to it by many, none have yet given any true account of its origin. The moft natural opinion would feem, that it was the juice of the tree fimply extravafated; but experience fhews that it has another origin: it is really the excrement of thefe *pucerons*; they receive no folid food into their bodies, all that is conveyed into them coming through their trunk, which is an extremely fine pipe; and as none but a very thin and pure juice can be received through fuch an organ, it is no wonder that the creature which lives wholly upon it fhould void no folid excrements. If a parcel of the *pucerons* be watched, it will not be long before one or other of them will be found voiding a fmall round drop of this liquor by the anus, and after that, feveral more; which all falling upon one another, form the vifible drop on which the ants feed. The creature feems in fome pain on the voiding this, and very often the hinder legs may be obferved affifting in removing it from the anus.

Mr. Reaumur obferved, that it was common to find feveral drops of this liquor on the leaves of fome trees; and that, tho' they were fluid and limpid, when firft evacuated from the animal, they became more and more thick afterwards, refembling honey after a few days, and after that drying up fo as not to be eafily removed from the leaves: and Mr. Geoffroy obferved, that the liquor of the bladder of the elm became, when dried, as hard as the gum of the cherry-tree. The drops of this liquor is not fo frequently found on the leaves of plants as might be expected, and that becaufe many of them are immediately devoured by the ants, and many others are dried up by the fun; but they may always be found collected in fome quantity in the bladders of the elm, and other trees inhabited by thefe creatures, as there the liquor is defended from the heat of the fun, and is fafe from being devoured. *Reaumur's* Hift. Inf. Vol VI. p. 49.

The two horns which are placed on the hinder part of the body of this infect are as fingular in their ufe as in their appearance; they are hollow, and they at times excrete alfo a liquor

quor as limpid and clear as that of the anus. This ftands in round drops at the end of one or both of them at once, and refembles heads upon pins. This liquor, tho' limpid in fome fpecies, is, however, reddifh and thick in others; as particularly in thofe of the willow: and as this feems plainly to be an excrement, the creature is very fingular in having its different paffages for thofe of different kinds. The liquor voided by the aperture at the extremity of the body, which refembles the anus in other animals, appearing to be the urine; and this by thefe two horns, the fæces of the bowels. At any time when there is not a drop to be feen upon either of the horns, if the body of the animal be gently fqueezed, a drop will always be forced out either from one or both.

The *puceron*, like moft other infects, changes its fkin three or four times before it arrives at its full growth. Thefe exuviæ perfectly refemble the animal in its natural ftate, the legs and other parts being all in their proper places; but whatever is the colour of the fpecies of *puceron*, thefe fkins which it cafts are whitifh. They lie in great numbers about the leaves where the creatures are, and among them there is ufually found a cottony matter. This at firft fight might be miftaken for the fkins, reduced to a kind of powder; but on a clofer examination, it appears to be truly filamentous, and on a nice infpection is found to be the natural produce of many fpecies of the animal. All thofe kinds of *pucerons* which are not fmooth and gloffy, as if varnifhed, have more or lefs of this cottony matter about them: in fome the whole roughnefs of the furface is made of it; and in others, it ftands in white fpots on feveral parts of the body.

Thofe *pucerons* which inhabit the bladders or leaf-galls of the elm and other trees, and thofe which live in the folded leaves of the black poplar, are all of the nature of thofe which produce the largeft fhare of this matter: they have it hanging in long ftrings in an odd manner from their bodies, and often are fo compleatly covered with it, that they look as if they had been wetted, and then rolled in meal.

On examining the leaves of fome plants and trees inhabited by thefe animals, there is feen a fort of collection of this down into parcels, fo that they refemble the white feathers of a bird in miniature. The leaves of the beech-tree afford thefe plumes in the greateft perfection, and frequently they cover its leaves in whole clufters, and are an inch or more in length. Thefe plumes, or clufters of plumes, feem all to grow out of the leaf, and are much thicker at their bafe than at their extremity; a great number of the plumes that compofe them being fhorter than the reft, and not running to the extremity. The longer plumes divide themfelves into two clufters near their origin, and thefe never unite again afterwards: when examined by the microfcope, each plume appears to be compofed of feveral other plumes or threads, like thofe of cotton, which are undulated, but not twifted together. Tho' thefe clufters of plumes feem to be fixed to the leaf, yet when more clofely examined, that is found not to be at all the cafe; but that they really proceed from the body of a *puceron*. The different threads or plumes arife from the different parts of the body of the animal, and altogether they hide it abfolutely from fight as it ftands on the leaf. When the bottom of the tufts are examined, however, there are always found either the bodies of the *pucerons*, or their exuviæ; for when they quit their fkins, they quit thefe filaments with them.

Tho' thefe long threads might feem a confiderable load for fo fmall an animal, yet when the creature is touched it always moves very brifkly, and as it creeps along, generally leaves fome of its plumes in the way; but in its motion, no other part of it than the head, and the foremoft pair of legs are feen. *Reaumur*'s Hift. Inf. Vol. VI. p. 53.

The young brood of this fpecies are green, and only by degrees acquire this white down; which at firft appears only in form of a farinaceous powder, and by degrees lengthens out as we fee it. The old ones alfo, when they have newly changed their fkins, have it not at all; and when it afterwards grows upon them, it is by thefe degrees, and in this manner. The leaves of the common bramble alfo afford this remarkable fpecies of *puceron*; and the common meadow crowfoot is frequently covered with clufters of them at its lower part, refembling a white mouldinefs. The filaments that cover the bodies of this fpecies of *puceron*, are not at all of the nature of the filky matter fpun by other animals; but feem to be produced from every pore of the body, and to iffue thence in form of fmall round globules of a liquid matter, which harden with the air, and adhering to one another as they iffue out, form this fort of plume, a congeries of which make the tufts we fee.

The male and female *pucerons*, as they are ufually fuppofed to be, differ greatly from one another in form, even in their time of growing; but much more eminently at the time of their maturity, the male having then wings, which the females never have. Lewenhoek and others, who have treated of thefe animals, have fuppofed that they all became at length little flies, that is, were winged; but this is a great error.

The young male *pucerons* may be diftinguifhed from the females by having a fort of eminence on their fhoulders, of a fquare form; which is owing to the young wings. The feveral changes of the fkin which thefe animals have, make no great difference in their form till the laft, when the males appear with their wings at liberty. A little before this laft cafting off the fkins, the males are feen to have a fort of tuberofity alfo on each fide, which is owing to the wings, folded up there within the fkin; but the females, tho' much larger than thefe, have no fuch protuberance.

The winged *pucerons*, when they have caft off their laft fkin, and have their wings loofe, do not, however, fhew them immediately; for they are folded clofely together, and the creature then appears like what it was before, being all over green, and having only two eminences on the fide: but in a quarter of an hour, the head and fhoulders change from their green colour to a fine fhining black, and the wings unfold and expand themfelves, and then cover a large part of the body, and extend themfelves to a confiderable length beyond it.

Thefe now appear animals wholly different from what they were before, and many of the flies which we fee in our gardens are of this kind: the animal, however, tho' it appear fo very different from its fellow infects, is much more like them, when clofely examined, than could be imagined. It ftill carries the great character of the genus, which is the having two horns growing out from the hinder part of the body, and ftill has its trunk, and lives by fucking the juices of plants. *Reaumur*'s Hift. Inf. Vol. VI. p. 57.

Notwithftanding, however, the general opinion, that the winged *pucerons* are all males, and the unwinged ones females, it appears that their manner of generation is yet unknown to us. This opinion was founded too haftily by fome from a fuppofed analogy of thefe and other infects; but later obfervations prove, that this is not ftrictly the cafe: for that the winged ones, as well as the others, bring forth young ones. Some have fuppofed, that thefe winged and naked *pucerons* were the offspring of different families of feveral fpecies living together; but the contrary is proved by this, that the winged ones are found to produce fome winged and fome naked ones; and the naked to produce both kinds in the fame manner. Some have imagined, that they found the male *pucerons* among the others, obferving fome of a flatter fhape, in whofe bodies there were never found any young ones, as there always were in the others, even when they were very young; but thefe have been fince found to be only fuch females as had already brought forth their offspring.

The young *pucerons* being themfelves filled with embryos, and that in every individual, fo that all that have been ever examined appear mothers, has given many ftrange ideas of the manner of their generation: many have imagined them all to be hermaphrodites; and as no copulation has ever been obferved among them, they are by fome fuppofed to be able to impregnate each itfelf. The later opinion, however, is, that when a female is once impregnated by a male, fhe will bring forth young ones already impregnated with others, and thus to the third or fourth fucceffion; fo that copulation is only neceffary to thefe animals once in three or four generations, and the children and childrens children of an old *puceron* that has had congrefs with a male, will bring forth young ones without having ever had any fuch congrefs. *Reaumur*'s Hift. Inf. Vol. VI. p. 59. See the articles Wood-*puceron*, Oak-*puceron*, &c.

Bladder Puceron, a fort of *puceron* that lives in bladders on the leaves of trees. See Puceron, *fupra*.

We often obferve on the leaves of different trees, a fort of roundifh bladders, which only adhere to the leaf by a fhort pedicle: thefe are a fort of fmall galls, and their figure varies much in the different kinds; fome are lefs round than others, and many are very rough on the furface; and fometimes they are long, terminating in a point, and being broader at the bafe than in any other part, and fuftained by no pedicle, but fixed immediately to the leaves.

The elm and afh afford us more frequent inftances of thefe than any other trees, and very often on the firft of thefe they grow to the bignefs of a nut, and fometimes much larger; and when they are grown to their full fize, they often take up the whole furface of the leaf. When thefe bladders are opened, they are found to contain a large number of *pucerons*.

If thefe bladders are examined at the time when they are but newly rifen, which ufually is in the beginning of June, on opening them there is ufually found in them only one *puceron*, and that always a female big with young; and in others more advanced, the parent infect is found furrounded with different numbers of her young ones. Thefe bladders have all of them at firft only one female *puceron*; but afterwards they have more, as they become larger; and the largeft of all are ufually found filled with a prodigious number of young ones. The newly rifen bladders are always found clofe and firm in every part, the aperture at which the female *puceron* had entered, being ufually neatly and clofely ftopped up. The queftion is, how this bladder was formed?

We very well know, that winged infects of feveral kinds prick holes in the leaves and branches of vegetables, and depofit their eggs in them; and that thence arife all the various fpecies of galls, the eggs hatching within thofe tumors into worms or maggots, and thefe finally becoming winged infects like their parents.

Malpighi has given an excellent account of the feveral fpecies

of

of these galls; but he has not mentioned any of them being produced by a viviparous insect, for the bringing up her numerous family: he has not omitted the bladders on the leaves of trees among the numbers of galls, but he has had no true idea of their origin; nor could this, indeed, have been any way found out, but by the observation that the creatures contained within them were of the same nature and origin with those on the surface of the same or other leaves.

There seems no doubt, but that each of the female *pucerons* found in the bladders of these leaves, has been herself the occasion and the maker of that bladder in which she is found so close shut up.

It would be natural to suppose, that the creature formed herself this lodgment when she found herself loaded with young, and under a necessity of being delivered of them: but this is not the case; for a female *puceron* taken in this state, and placed upon a leaf, makes no attempt towards the making herself such a lodging; and there are taken out of the new-risen bladders many single animals of this kind, which are so far from being about producing their young, that they are not full grown. These, however, are always females.

The method of the formation of them seems to be this: as soon as the female *puceron* is produced, she fixes her trunk into the leaf to suck its juices; the consequence of this in all the *pucerons* is, that the surface of the leaf separates a little from the nervous part: in the common cases the creature takes no advantage of this, but only continues sucking the juices; but in this kind, the female, as soon as she has made the separation between the parts of the leaf, gets into the cavity that is formed there, by enlarging the orifice first made by the trunk, till it will admit her body. When once in, she works forward in a strait line, and the hole behind her soon closes up, as there was no rupture, but only a stretching open of the parts of the leaf. The female thus finds herself in a secure place, and the elevation she makes in the leaf is scarce perceivable, only appearing as an oblong small species of gall. The mark of the aperture at which she made her way in, is always to be seen at some distance behind her, tho' usually very neatly closed up: thus the whole continues till the creature produces her young. But then the scene is quite altered; the young ones begin to suck as soon as produced, and as they usually seize upon the sides of the small gall, already formed for that purpose, this derives more juices than otherwise would flow into it; and it begins to elevate itself much higher, and forms a tubercle of the shape of a nut or pear.

Its growth in this case is entirely analogous to that of the common galls on the branches of trees, *&c.* and all the difference in the shape of the several bladders, is owing to the manner of the young *pucerons* sucking: for if they suck much at its base, that enlarges and becomes the broadest part, as is the case in the conic and pointed ones; but if they let this alone, and suck only the sides and upper part, they swell while this does not, and consequently this forms a sort of pedicle to the growing bladder. *Reaumur*'s Hist. Inf. Vol. VI. p. 33.

Ver PUCERON. See VER *puceron*.

Wood PUCERON. See WOOD.

PUCKAUN *beady*, in natural history, a name given by the people of the East Indies to a peculiar species of orpiment, which they use in medicine.

They find it on the hills and on the banks of rivers. It is prepared by several tedious processes, and then is given with success in a diabetes.

PUDDINGS, in a ship, are ropes nailed to the arms of the main and fore yards, near the ends, and then at three or four due distances inwards one from another, in order to keep the robbins from galling or wearing asunder upon the yards, when the top-sail sheets are haled home.

They call also those ropes which are wound about the rings of anchors, to save the clinch of the cable from being galled with the iron, by this name; so that when the ring is so served, it is called the *pudding of the anchor*.

PUDDING-*stone*. See the article OCULATUS *lapis*.

PUDENDA (*Cycl.*)—It is remarkable, that among the fish-tribe all that are oviparous have no *pudenda*, properly speaking; that is, they have no penis or vulva, unless the ovaria of the females and the vasiculæ seminales of the males may be called by that name.

The viviparous fishes, on the other hand, as the cetaceous fishes in particular, and many kinds of the cartilagineous, have the penis and vulva, distinctly and properly so called. *Artedi* Ichthyolog.

PUDIANO, called also *pœdiano*, and by others *vermelho*, *apaimixira*, and *tetimixira*, a fish of the size of a middling pearch, but not so broad as that fish.

Its head is small, its nose pointed, and the upper part of its mouth furnished with very sharp teeth; its lower part with others extremely minute. Its eyes are prominent, and the rays of its back fin are rigid and prickly. Its scales are extremely small, and so closely laid, that it seems smooth to the touch. Its whole body is of a gold-yellow; but that the upper part of its head, and its back to the end of the back-fin, are of a very beautiful purple. The rim or edge of the belly-fin is also purple, and the rest of a gold-yellow. It is a wholesome and well tasted fish. *Ray*'s Ichthyol. p. 339. *Marggrave*'s Hist. Brasil.

PUDIANO *verde*, in zoology, the name of an American fish of a very remarkable colour, and very well tasted and wholesome. See Tab. of Fishes, N°. 60.

It is of an oblong shape, and its usual size is about ten fingers long, and three broad in the broadest part; for towards the tail it is but about half that breadth. Its mouth is small, and its upper jaw furnished with two long teeth, and a great number of short ones; and its under one with four long ones, and a like number of small ones. Its back-fin is very long, and is supported by prickly rays. It is of a yellow colour, and variegated with longitudinal streaks of blue. Its tail is not forked, and is of a reddish brown, variegated with a bluish green, and has a border of green at the end. Its scales are broad, and are so disposed, as to represent so many cubes. These are all of a fine yellow, and each has a rim of a bright blue all round its edges; and the whole fish is very elegantly variegated with blue, yellow, green, and white streaks. *Marggrave*'s Hist. Brasil *Willughby*'s Hist. Pisc. p. 340.

PUFF-*ball*, the common English name for the *fungus pulverulentus*, or lycoperdon. See LYCOPERDON.

The dust contained within this body, (which, when it is crushed, flies out in an inconceivably fine powder, in form of a cloud of smoak) when examined by the microscope, appears to be a multitude of regulary figured, tho' extremely small bodies. These require the most powerful magnifiers to distinguish them, and are found to be little globules of an orange colour, and somewhat transparent; and so small, that the cube of the diameter of a hair, would be equal to an hundred and twenty-five thousand of them. In other species of this mushroom, the globules are evidently seen to be so many *puff-balls*, being of a darker colour, and having each a little stalk or tail: by means of these stalks they penetrate into the ground, when shed from their parent plant.

The dust of these mushrooms is very hurtful to the eyes, and we have had instances of persons being blinded for a long time by it, with violent pain, swelling, and inflammation; and this is probably owing to the sharpness of these almost inconceivably minute stalks or tails. *Baker*'s Microscope, p. 255.

PUFFIN, in zoology, a name by which some call the anas arctica Clusii. See PUFFINUS, *infra*.

PUFFINET, in zoology, the name of a bird known among authors by that of the *columba Groenlandica*, or the Greenland or sea turtle-dove.

It is common on the northern coasts, and is black all over, except two small spots on its head: but it is pretended by some, that in winter it turns white. *Ray*'s Ornithol. p. 245.

PUFFINUS, in zoology, the name of a water fowl, with its three fore-toes connected by a membrane; but its hinder ones loose, and with a sharp and crooked beak. It is called in English the *puffin*.

It is larger than the tame pigeon: its head, neck and back are black: its breast and belly white: its beak is two fingers breadth long, and its base covered by a naked membrane, and has on each side a furrow, running from thence to the end of it: its wings are very long, and its tail a hand-breadth long, and black: it is extremely common in the Isle of Man, but is so fat, that its flesh is accounted unwholesome unless it is salted: it is also common in the Scilly islands. They breed only in the culf of Man, an uninhabited part of the first mentioned island, and each female lays only one egg.

They lay in rabbit holes, and as soon as the young are hatched, they follow their parents all day to sea, returning only in the evening. The people take them early in the morning, about the time of their going out, and that every man may remember how many he takes, he always cuts off one of the legs, and keeps it in his pocket; hence the vulgarly obtained opinion, that *puffins* have but one leg. *Ray*'s Ornithol. p. 252.

PUGNAX *avis*, in zoology, the name of the bird called in English the *ruffe*, and the female of which is the *reeve*. It has its Latin name from its quarrelsome disposition, the males being always fighting. See the article RUFFE.

PUGNITIUS, in zoology, the name of the common stickleback, or barnsticle, called also from its spines *aculeatus*, and by some authors *spinachia*, *turonilla*, and *centiscus*.

It is a very well known fish, and is found every where in new dug ditches, *&c.* where no body can perceive how it comes. Hence the vulgar have an opinion, that it breeds there equivocally and of itself, without the help of parents of its own kind; and that from it all other fishes are bred.

These are idle opinions: the smallest animalcule is not produced in putrid matter otherwise than by the egg of a parent animal; this origin will, therefore, hardly be believed of larger, and, as they are called, more perfect animals. These small fish are so far from peopling ponds with other fish, that they are very great devourers of the spawn of larger fish, and do infinite mischief in ponds.

There are two ſpecies of this little fiſh, the one larger, of two inches or more in length, and conſiderably thick. This has but five prickles, three on the back and two on the belly: this laſt is fixed to a penniform bone, very hard and ſtrong; for inſtead of belly-fins, this has two triangular bony laminæ. It has no ſcales, but its ſides are defended with a bony armature, reaching from the ſpines on the back to thoſe on the belly. It can raiſe or depreſs its ſpines at pleaſure. This ſpecies is common in our ditches; and they ſometimes ſwim in immenſe ſhoals together in the ſea.

The other is the ſmaller kind: this is ſhorter and much ſlenderer than the former, ſo that it appears proportionably of a longer figure. It has ten or eleven ſpines on its back, and theſe not ſet in an even row, but alternately bending one to the right, the other to the left; and it has bony laminæ inſtead of belly-fins, and two ſpines or prickles on them; and one behind the anus. This ſpecies has not the bony armature on its ſides that the larger has. It is common in our ditches. *Ray*'s Ichthyol. p. 341. ſeq.

PUGNITIUS *Lingus*, in zoology, the name of a Weſt Indian ſea-fiſh, caught about Chili and in ſome other places, and approaching in many particulars to the European *pugnitii*.

It is a ſmall animal; its body is ſquare, and of a tender conſtruction; of the thickneſs of a finger, and of five, ſix, or ſeven inches long, becoming gradually ſmaller towards the tail: its ſkin is ſmooth, and its back is black; its belly yellow: its head reſembles that of the pike, but that the noſe is ſomewhat longer: it has two fins at the gills, one of a triangular ſhape on the back; and from this to the neck there are placed a row of fifteen prickles, which bend a little backward, and are not connected by a membrane. On the middle of the belly it has alſo two ſpines at the two ſides, and one behind the anus: behind this there is a fin anſwering to that on the back, and the body is terminated by a fine ſmall tail. *Schonefeldt*'s Hiſt. Piſc. *Ray*'s Ichthyol. p. 340.

PULCHER *piſcis*, in ichthyology, a name given by Gaza to the fiſh commonly known by the name of the *uranoſcope*, or ſtargazer. See URANOSCOPUS.

It is a ſpecies of the trachinus, and diſtinguiſhed by Artedi by the name of the *trachinus*, with many beards on the lower jaw. See TRACHINUS

PULEGIUM, *penny-royal*, in botany, &c. a name given by authors to the common water-mint. Vid. *Linnæi* Gen. Pl. p. 271. *Tourn.* Inſt. Bot. p. 189. *Rivin.* Vol. I. p. 31, 32. See alſo the article MENTHA.

Penny-royal is among the firſt plants in eſteem in the preſent practice, as well as in former ages, as an attenuant and uterine. It promotes the menſes, and forwards delivery. It is good in flatulencies and ſuppreſſions of urine, and by many is greatly recommended in dropſies, jaundices, and other chronic diſtempers. It communicates its virtues very readily to water in infuſion, and its ſimple water drawn by the alembic, has, perhaps, more virtue than any other kept in the ſhops. Its eſſential oil is ſometimes, tho' rarely, uſed in the ſame intentions with the water.

PULEX, the *flea*. It is to Signior Redi that we owe the true hiſtory of the generation of this common and troubleſome animal.

The *flea* lays its eggs, and from each egg is hatched a ſmall worm: this worm ſpins itſelf a bag of ſilk, in the ſame manner that the ſilk-worm does; and out of this bag it comes at laſt in the perfect form of a *flea*, as the other does in its winged ſtate.

The *flea* depoſits its eggs on the bodies of dogs, cats, and other animals, and on the clothes of men, or the beds, and other places where they ſleep. Theſe eggs being round and ſmooth, ſlip eaſily down till they come into ſome fold of the clothes, or ſome other place, where they are hatched. In this place each egg produces a ſmall white worm of a ſilvery appearance; theſe worms feed on the white ſcurfy matter which is found in great plenty on the ſkins of dogs and other animals; and they are alſo found among the folds of linnen in drawers and other places: they are a fortnight in arriving at the full bigneſs of the worm ſtate, and will roll themſelves cloſe up into a ball, in the manner of the wood-louſe, when touched.

They ſoon after this ſpin themſelves their web, in which they lie a fortnight, and then come out perfect *fleas*.

The *flea*, if examined a day or two before its full growth in the bag, is found to have all its parts and lineaments; but it is ſoft and white. After this it gradually becomes hard and coloured, and when it comes out of the bag, is as ſtrong and large as it ever is to be.

PULEX-*eaters*, a name given by naturaliſts to a ſort of worms frequently found on the leaves of trees, where they devour the animals called *pulices arborei*. Vid. infra.

Of theſe there are ſeveral ſpecies, which owe their origin to the eggs of different creatures; for they are none of them in their ultimate ſtate in this their time of feeding. According to the different animals whoſe eggs they are hatched from, theſe are of different form and ſtructure: ſome are hexapodes, or endued with ſix feet; theſe belong to the beetle tribe, and finally change into beetles like the parent animal from whoſe eggs they ſprung: others have no legs, and are produced from the eggs of flies of various kinds: and finally, others are genuine caterpillars, tho' ſmall; but theſe are the moſt rare of all.

The two general kinds are the hexapodes, or beetle-worms, and the apodes, or fly-worms. The fly which gives origin to the laſt of theſe is a four-winged one, and takes care always to depoſit her eggs in a place where there are plenty of the *pulices*, uſually on the ſtalk or young branches of a tree in the midſt of large families of them. The worm, as ſoon as hatched, finds itſelf in the midſt of abundance of food, preying at pleaſure on theſe animals, which are wholly defenceleſs. The ſtalk of the elder and woodbine are frequently found covered over with theſe *pulices*, and among them there may uſually be found one or more of theſe deſtroyers feeding at will, ſucking in the juices from their bodies, and then throwing away the dry ſkins. Beſides the worms of this four winged fly, there is one of a two-winged waſp-fly, very deſtructive of theſe animals. *Reaumur*'s Hiſt. Inſ. T. 1.

PULEX-*arboreus*, in natural hiſtory, the name given by Mr. Reaumur to a very large genus of ſmall animals. They are a kind of half-winged creatures; they have granulated antennæ, and ſome of them, in their moſt perfect ſtate, have complete wings. Theſe are diſtinguiſhed from the others by the name of *muſca pulex*, or the *winged-pulex*.

The ſeveral ſpecies of theſe creatures are of different colours; ſome are brown, others yellow; but the moſt frequent are green. They all feed upon the leaves of trees, which become withered and curled up on their eroding them; and they are ſo common, that wherever a leaf of a tree is found curled up, or of a different form from the others, it is highly probable theſe animals are on it, or that it is their work. Among trees the willow and the roſe are the moſt infected by them; and among plants, the bean and the poppy. They live a ſocial life, multitudes of males and females being found together. The females are eaſily diſtinguiſhed from the males, by their being thicker in the body, and having larger bellies.

It is very wonderful, that of all the known animals of the winged kind, theſe are the only ones which are viviparous. This is eaſily ſeen beyond a poſſibility of doubt; for on examining a cluſter of them together, it is a common thing to ſee, by the help of a ſmall magnifier, a female in the act of parturition; and the author of this account frequently ſaw the young *pulex* protruded out, from a paſſage near the anus of the female, perfectly formed. He had ſuſpected this from the total want of eggs among ſo numerous a tribe of animals, and from their remarkably ſpeedy propagation, and was thus convinced of it by ocular demonſtration.

They are armed with a tender and flexile proboſcis, with which they ſeize hold of the young ſhoots of the tree: they live upon twiſting the proboſcis round it. Theſe creatures are always ſeen naked and expoſed, ſtanding on the outſide of the ſtalks and leaves, and ſucking in their juices for nouriſhment with their proboſcis. But there is another ſpecies of them, which are alike viviparous, and agree with them in all reſpects, except in their manner of living. Theſe get into the inner ſubſtance of the leaves, like the worms called *aſcarides*, and feed on the parenchyma, being defended from all injuries by living between the integuments. In this caſe, the leaves they bury themſelves in become ſcabrous and deformed, and produce a ſort of galls: ſo that Malpighi erred in ſuppoſing all the galls of trees to be produced by the animals hatched of the eggs of ichneumon flies; ſince theſe animals which are viviparous, and are of a very different kind from the worms of the ichneumon flies, equally produce them. A female of the ſpecies here treated of has been ſeen to bring forth ſeven young ones in one day; and thus, from reſiding alone in the tubercles which ſhe had formed on a leaf, ſhe in a little time becomes the mother of a numerous family; each of which raiſes its own tumor or gall on the leaf, which at firſt are ſmall and round, and of a beautiful red like kermes.

Such of theſe as are of the male ſpecies have a certain time of reſt, in which they lie buried in a ſilky matter, and afterwards become winged, flying nimbly about; whereas the females never are able to fly, but remain always half-winged. It is to be obſerved, however, that there is a different ſpecies of winged inſects frequently found flying about the female *pulices*, as well as their own males; ſo that all the ſmall-winged inſects about them are not to be thought of their own ſpecies. Theſe do not greatly differ in figure; but the one are harmleſs, and the others have ſtings, and hurt any part of the body on which they fix. *Reaumur*'s Hiſt. Inſ. T. 1. See PSEUDO-*pulex*.

Locuſta-PULEX. See CICADULA.

PULMONARIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a cylindric, pentagonal, perianthium, conſiſting of one leaf divided into five ſegments at the edge, and remaining after the flower is fallen. The flower conſiſts of one petal, in form of a cylindric tube, of the length of the cup, with its edge ſlightly divided into five ſegments, and its mouth open. The ſtamina are five very ſhort filaments, ſituated in the opening of the flower. The antheræ are erect, and converge one toward another. The piſtillum has four germina. The ſtyle is ſlender and ſhorter than the cup, and the ſtigma is obtuſe and emarginated. The cup, without ſuffering any changes, ſerves in the place of a fruit, containing in its bottom four roundiſh-leaved obtuſe ſeeds. *Linnæi* Gen. Pl. p. 59.

The characters of *pulmonaria*, according to Mr. Tournefort, are

are these: the flower consists of one leaf, and is funnel-fashioned, and divided into many segments at the edges. The mouth is wide, and resembles a sort of basin. The cup is tubular, and usually of a pentangular form, and divided into five segments. From this arises a pistil, which is fixed in the manner of a nail to the lower part of the flower, and is surrounded by four embryos, which afterwards ripen into so many seeds, which are contained in the enlarged cup. *Tourn.* Inst. p. 136

The species of *pulmonaria*, enumerated by Mr. Tournefort, are these: 1. The common spotted-leaved *pulmonaria*, resembling buglos. 2. The common broad-leaved white-flowered *pulmonaria*. 3. The blue-flowered Alpine *pulmonaria*, with soft and roundish leaves 4. The plain-leaved not spotted *pulmonaria*. 5. The echium-leaved *pulmonaria*. 6. The white-flowered *pulmonaria*, with echium leaves. 7. The red-flowered echium-leaved *pulmonaria*. 8. The blue-flowered, echium-leaved *pulmonaria*. 9. The narrow-leaved Alpine *pulmonaria*. 10. The soft *pulmonaria*, with the strawberry smell. 11. The annual Cretic *pulmonaria*, with bladder cups. 12. The *pulmonaria*, with roundish, plain, green, not spotted leaves.

The figure of the flower-cup is what principally distinguishes the *pulmonaria* from the buglofs, &c. and the plants of it may be usually known when not in flower, by their long, rough, and not divided leaves, which in almost all the species are spotted, so as to resemble the tabid lungs of an animal, whence it had its name. *Tourn.* Inst. p. 137.

The common spotted *pulmonaria*, or, as we vulgarly call it, *sage of Jerusalem*, is esteemed an excellent medicine in many of the disorders of the lungs. It has been known to do great service in spittings of blood, and stands greatly recommended, externally used, as a consolidator and healer of old ulcers, as well as fresh wounds.

PULSATILLA, *pasque-flower*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, consisting of several leaves disposed in a circular form. The pistil arises from the center of the flower, and is surrounded by stamina. The pistil becomes at length a fruit, to which there are fixed a number of seeds, each of which terminates in a slender filament. The *pulsatilla* has, like the anemone, a regular set of leaves growing from one part of the stalk under the flower; but differs from it in having its seed naked, and terminated by the long filament just mentioned.

The species of *pulsatilla*, enumerated by Mr. Tournefort, are these: 1. The purple *pulsatilla*, with thick leaves and a large flower. 2. The double violet-coloured *pulsatilla*, with fimbriated flowers. 3. The marsh *pulsatilla*, with more finely divided leaves and smaller flowers. 4. The finely divided-leaved or marsh *pulsatilla*, with paler coloured flowers. 5. The *pulsatilla* with small blackish flowers. 6. The smallage-leaved spring *pulsatilla*, with larger flowers. 7. The smallage-leaved spring *pulsatilla*, with smaller flowers. 8. The smallage-leaved autumnal *pulsatilla*. 9. The roundish-leaved *pulsatilla*. 10. The *pulsatilla* with red, obtuse-leaved flowers. 11. The white-flowered *pulsatilla*. 12. The double white Pyrenean *pulsatilla*. 13. The celeri-leaved yellow-flowered *pulsatilla*. 14. The wild parsnep-leaved yellow *pulsatilla*. 15. The yellow rough-leaved Alpine *pulsatilla*. *Tourn* Inst. p. 284.

PULSATOR, a name given by some writers to that species of beetle, commonly known among us by the name of the *death-watch*, and about which so many superstitious fancies prevail.

The manner of the creature's making its noise is this: it lifts itself up on its hind legs, and somewhat extending, or rather inclining its neck, strikes down its face with great strength and agility, upon any substance on which it happens to be placed. It is often found on the matted bottoms of old chairs, and seems to use the motion which makes this noise, in order to get its food. It is usually found standing on a part of the sedge where the outer covering is off, and the pithy part exposed; and it usually works at the side or edge of this place, in order to the getting off more of the outer bark. Where it is found there are usually several of these bald places in the sedge, which seem to have been places where it was before employed in getting its food. Every stroke the creature gives may be seen to have a sensible effect upon the sedge, and where it strikes a sound part, the impression is seen to be a dent as large as a silver penny.

The creature is called by some *scarrabæus galeatus*, from a sort of galea, or helmet, which it wears. It is about a quarter of an inch long, and is of a dusky brown colour. Its helmet is very broad in comparison of its bulk, and when the creature is at rest, it draws in its head under this covering.

PULSE (*Cycl.*)—It is certain that the climate will alter the *pulse* of persons, and on this is founded the observation of *pulses* being naturally various in the people of different nations. The *pulses* of Frenchmen are said to be more equal and quick, and those of the British, Dutch, and Germans, more irregular and uncertain; and this is to be jointly attributed to the air of the country, and to the manner of living.

In general, the higher and nearer the sun is, the quicker is the *pulse*; and the lower and farther off, the slower. In rainy seasons, the *pulse* is more free and quick, because of the smaller pressure of the atmosphere. It is more impetuous in the spring; more equal after a quiet sleep; weak and uncertain in men very intent upon business.

Melancholy renders the *pulse* extremely inconstant, probably through the great thoughtfulness of such men; in bilious tempers it is high and strong; in sanguine, more equal and regular than in any: in the phlegmatic, equal enough; but more slow: in children, especially infants, the *pulse* is very small; and in old men it is extremely uncertain: in glutonous people it is dull and slow, unless by drinking it is made stumbling and vertiginous: this sort of *pulse* also frequently foretells sudden death By too sparing a diet it becomes small and slow, and always abates upon fasting. By the passions the *pulse* may be also greatly altered; but most of all by fear, joy, and anger. In fevers the *pulse* is varied according to the beginning, heighth, and declination. In scorbutic and hysteric persons it is very uncertain: in hydropical persons it is much stopped and interrupted by stagnant humors: in the gout it is free and expedite: in the plague, as in the asthma, it is mightily oppressed, unless freed by the hot fit. In general, any variation of the *pulse* certainly denotes some alteration in the habit of the body.

The *pulse* is unequal either in regard to time or strength; that is, it either strikes quicker and slower, or stronger and weaker. The first is common in most acute distempers, and does not threaten any immediate danger; but the latter, both in acute and chronic cases, is always a dangerous symptom: very often it is the forerunner of death, which happens two or three days after this is first observed. It is said to be interrupted when the strokes are much smaller and weaker than at other times, or their intervals much greater. This first shews a great decay of strength; and the latter, which is, as it were, a cessation for a time, denotes approaching palsies, apoplexies, and the like terrible distempers, and sometimes death itself

The intense *pulse* is when the stroke is very hard, the parts being, as it were, upon the bent; or else this strength is made up by the multiplicity and frequency of less mications, as in the heighth of acute fevers.

The remiss *pulse* has strokes less quick and strong, and in sickness shews more danger than the other. The superficial *pulse* shews an exact temperament of body, as also a free and easy temper of mind.

The deep *pulse* shews a disposition to melancholy, asthmas, and lethargies, and is more frequent in the aged than in young people.

The leaping *pulse* often shews no great danger, but the trembling *pulse* is usually a fatal symptom, after which very few people recover.

But of all others the wandering *pulse* is the most terrible and fatal; this is felt sometimes in one part of the artery, and sometimes in another, and sometimes in no part at all. This is a certain fore-runner of death, and that usually very speedily following; and if great power in nature gives a short reprieve after this, it is only a very short relief. *Abercromb.* de variat. Pulsus.

The *pulse* has been observed to beat faster in persons electrified. Phil. Trans. N°. 478. p. 59. See ELECTRICITY, *Cycl.*

PULSILOGIUM, a name given by authors to a pulse-watch, or instrument to measure the celerity of the pulse. Sanctorius was the first inventor of this machine; but several have since spoke very largely in praise of it, and Sir John Floyer wrote a treatise on this subject.

PULSUS *latus.* See LATUS *pulsus.*

PULVERATICUM, in Roman antiquity, the fee paid to purveyors for their trouble; also a sum exacted from the provincial cities by their garrisons. *Pitisc.* in voc.

PULVILLUS, in surgery, a term used to express a little pledget-bolster, or compress

PULVINARIA, in Roman antiquity, cushions upon which the statues of the gods were laid in the temples, at the time that thanks were given for some signal victory. *Danet* in voc.

PULVIS (*Cycl.*)—PULVIS *e bolo compositus*, a powder prescribed in the late London pharmacopœa, and intended to be used in the place of the *confectio Fracastorii* or *diascordium*. It being supposed that this medicine was by its author meant as an alexipharmic, and being now principally used as an astringent, it was thought necessary to make this separate medicine.

This powder is composed of bole armenic, half a pound; cinnamon, four ounces; and tormentill-root and gum arabic, of each three ounces, made together to a powder. *Pemberton's* Lond. Disp. p. 311.

PULVIS *bezoarticus*, the name given in the late London dispensatory to the powder commonly called *Gascoign's powder*.

This is now ordered to be made only of crab's claws, one pound; prepared pearls and red coral, of each three ounces; and oriental bezoar, an ounce. The amber and hartshorn are left out of the composition, as improper or inefficacious ingredients; and the whole ordered to be kept also without the bezoar, and called by the name of *pulvis e chelis cancrorum compositus*, the name the Gascoigne's powder used to be known by. *Pemberton's* Lond. Disp p. 313.

PULVIS *e cerussa*, a medicine prescribed in the late London pharmacopœa, in the place of the white troches of Rhases or Razi. See TROCHE.

The late compositions of that medicine had been much more com-

complex than the original receipt of that author, and the college have therefore retrenched the number of ingredients in them; and as the medicine is always to be powdered for use, it is now ordered to be kept in the form of powder.

It is thus prefcribed there: take cerufs, five ounces; farcocolla, an ounce; gum tragacanth, half an ounce; make the whole into a fine powder. *Pemberton*'s Lond. Difp. p. 312.

Pulvis *contrayervæ compofitus*, the name given in the late London difpenfatory to the compofition ufually called *lapis contrayervæ*.

The preparation is alfo there made much lefs complex, by leaving out the lefs powerful abforbent powders, and ufing the compound powder of crabs claws in the place of all.

This is now ordered to be made only of the compound powder of crab's claws, a pound and half; and contrayerva-root, five ounces. *Pemberton*'s Lond. Difp. p. 313.

Pulvis *e myrrha*, a form of medicine prefcribed in the late London difpenfatory, to fupply the place of the troches of myrrh. The compofition is the fame but for the omiffion of one or two of the ingredients, fuppofed not of the fame virtues with the reft, or very difagreeable to the tafte.

It is ordered to be made thus: take of dried leaves of rue, of dittany, of crete, of myrrh, each an ounce and half; of affafœtida, fagapenum, Ruffia caftor, and opopanax, each an ounce, beat altogether to a fine powder. *Pemberton*'s Lond. Pharm. p. 314.

Pulvis *e fcammonio*, a name given in the late London difpenfatory to the purging powder commonly called the *Earl of Warwick's powder*.

It is, however, wholly altered here, the cryftals of tartar and diaphoretic antimony being left out, and the medicine ordered to be made only of four ounces of fcammony, and three ounces of burnt hartfhorn reduced together to a fine powder. *Pemberton*'s Lond. Difp. p. 315.

Pulvis *e fuccino*, *amber-powder*, a form of medicine prefcribed in the late London pharmacopœa, to ftand in the place of the troches of amber, or *trochifci de carabe* of former difpenfatories.

The compofition of the powder is this: take prepared amber and gum arabic, of each ten drachms; juice of hypociftus, balauftines, and Japan earth, of each five drachms; olibanum, half an ounce; ftrained opium, a drachm; mix all together into a fine powder. *Pemberton*'s Lond. Difp. p. 316.

Pulvis *fœcundans*, in natural hiftory, a name given by late writers to that fine powder which is contained in capfules upon the ftamina or threads in the flowers of plants, and is called by fome Englifh writers the *maledufl*, and in general the *farina* of flowers.

This duft was for many ages looked upon as a recrement of the plant; but it has of later times been found to confift wholly of organical bodies, which are in reality the embryo plants; and entering into the feeds in the capfules, while yet buried in the ftyle, they fœcundate them, and put them in a ftate to vegetate and produce their fpecies. On the moft accurate examination, however, with microfcopes, the farina, or *pulvis fœcundans* of plants, has never been found to carry any likenefs to a *plantula feminalis*, or the rudiments of the plant which was to be produced by it. All that the microfcope does in this cafe, is but increafing the apparent magnitude of the particles of the powder; but they are found, when thus viewed, to be no other than a congeries of globules, which are all alike in the fame fpecies, and compofed of fibres and vafcules wrought together in fuch a curious manner, to the keeping whole as long as neceffary, and burfting when neceffary, that it appears evident they are deftined for fome very great ufes. See Tab. of microfc. Obj Clafs 2.

Verdrefius, in the Acta eruditorum, has given a very curious detail, and has figured and defcribed fifty kinds of this duft, moft of which are confiderably different from one another; tho' fome are nearly alike. He obferves, that in all the number of flowers he examined, he found no farina, or *pulvis fœcundans*, that did not refemble one of thefe fifty; and that, therefore, whoever engages in this curious refearch, fhould firft obferve thefe, and then refer the others to one or other of them, as they next approach them, and mention their differences, if any, by way of characters, by which they might always be known. Act. Erudit Ann. 1724. p. 410.

The author of this curious treatife, from a multitude of experiments, feems to think thefe globules of duft rather to reprefent the tefticles of male animals, than any other part of the organization of any known body. The numerous fibres they are compofed of, which are convoluted and twifted in a moft remarkable and intricate manner, and the veficles contained in their fubftance among thefe fibres, fhew a great refemblance to the teftes in ftructure, and in their apparent ufes.

The principal farinæ he defcribes, are thofe of the yellow water iris, or flag-flower, which are of an oval figure, fomewhat hairy, and covered either in part or entirely with a thin membranous coat. The tulip farina, which is flat, broad, and fomewhat angular at one end, tho' rounded at the other. The honey-fuckle farina, which is broad and truncated at one end, and roundifh, but fomewhat pointed at the other. The farina of the iris-leaved yellow lilly, which is oblong, pointed at one end, and rounded at the other; and when feparated perfect from its capfule, has a tail at the rounded or largeft end. The farina of the hypericum, which is oblong and flender, truncated at both ends, and marked with a deep longitudinal furrow on one fide, refembling the channel in the midft of the feeds of corn or oats, and ferving to the fame purpofe, the opening of the granule. The marfhmallow farina, which is like the mallow and holy oak, a very beautiful object, being round granules, furrounded with a regular circle of fpines or prickles. The Indian crefs has a farina, which in moft lights appears of a triangular figure. The lyfimachia, or willow-herb, has a farina refembling that of the hypericum, but fhorter and thicker, truncated at both ends, and with a longitudinal furrow, tho' but a flight one. That of the fcabious is fmoother than moft others, and approaches moft of all to a globular figure. That of wormwood is alfo globular, and fmall, and when feparated entire, has a ftalk or pedicle like that of the yellow lilly. The farina of the clematitis is very fingular, it being of a globular figure, but confifting of one globule enclofing another; or of a pale-coloured globule, contained in a thick brownifh hufk, which opens in one determined part, and lets out the globule it contained. That of the white jeffamine confifts of half globules, or a fort of hemifpheres, flat on one fide, and regularly rounded on the other.

The farina of tobacco is oblong and flender, and pointed at both ends, fometimes very fharply, fometimes more obtufely, according to its ftate of ripenefs. This has alfo an oblong furrow running from end to end on one fide, which is the place where it is to open, as the hypericum and fome others have. The farina of the paffion flower confifts of very large dufky-coloured globules, which, when feparated entire, have tails or pedicles; but thofe very fhort. That of the gourd is a more elegant object than almoft any other: it is round, and furrounded with a row of flat and obtufe rays, refembling the mallow farina, except that they are not pointed. The cucumber, tho' a plant nearly allied to this, yet produces a fimple, fmall, and roundifh farina. The cabbages of fome kinds have farinæ compofed of fimple, oval bodies; in others thefe globules are more oblong, and refemble very perfectly the naked grains of wheat, having the fame fort of furrow running longitudinally from end to end. The duft of the hyacinth is very long and flender, often crooked, and always obtufe at one end, and pointed at the other. The farina of fome of the fpecies of clary is very large, perfectly round and fmooth, and has the mark of an opening in one part. It is probably like that of the clematitis, one globule contained within another, and this the opening thro' which the inner one is to pafs. The author of thefe curious obfervations has given good figures of thefe and of the other of the fifty of his farinæ, to which we refer the reader. Act. Erudit. Ann. 1724 p. 411.

Puteolanus Pulvis, in natural hiftory, the name of a foffile fubftance, found in form of powder, and famous for its confolidating under water. The accounts of it feem, however, to be a little erroneous.

The fubftance itfelf is a pale greyifh powder, compofed of particles fo extremely minute, as to efcape the diftinction even of the beft glaffes, and appear, when viewed by the microfcope, only a loofe, very fine, irregular powder. It has among it a few fmall fpangles of talc, and being fhook up in a vial of water, leaves a whitifh muddinefs in it, which is very long in fubfiding. If wetted with falt-water, it immediately dries into a firm folid mafs, like a ftone. It does the fame alfo in common water; but the mafs is lefs firm.

The antients were well acquainted with this fubftance and its properties. It is faid, indeed, that on running down into the water, it becomes a hard ftone, while it remains under it; but this is probably a miftake, arifing from this, that the powder was continually running down the hills into the fea, and lodging on their fides in large quantities in many places; when thefe maffes became wet with the waves, in ftorms or high tides, and afterwards deferted by them, they naturally hardened into fo many maffes of a fort of ftone: and thefe were probably what authors have feen and defcribed, for they never, probably, fearched for thefe maffes under water. The principal ufe of this powder among the antients, was in mixing with their cements for buildings funk into the fea. It is at prefent well known in France and Italy, as an ingredient in that fort of plaifter they call *pozzolane*.

The remarkable quality of its coalefcing on its being mixed with water, is probably owing to its having in its compofition a quantity of a certain earth known in almoft all ages and countries for coalefcing into a kind of plaifter without previous burning. The antients knew this earth by the name of *gypfum tymphaicum*; and we, by that of *calx nativa*. It is very common on the fides of hills in many parts of Italy. *Hill*'s Hift. of Foff. p. 573.

PUMICE *(Cycl.)*—There have been many different conjectures about the nature and origin of this fubftance; but the very earlieft writers of antiquity, and the moft judicious of the later ages, agree, that it is no native foffile, nor in its original condition but a mere cinder, or remainder of fome other foffile body, calcined by a violent fire.

This may have been either fubterranean and unfeen, or perhaps fince extinguifhed; or that of the well-known burning

in-1

mountains, on and about which *pumices* are conftantly found, and that in vaft abundance. The more violent explofions of thefe may alfo, at one time or other, have toffed vaft quantities of *pumices* to places fo diftant as to make people forget from whence they came; or into feas, whofe tides and ftorms may have carried them to other fhores, near which no fuch repofitories of *pumices* are fituated; and this might very much puzzle and miflead people about its true nature and origin

The great quantities of *pumi es* found in this manner, far from fires by which they might have been formed, floating on the furface of the fea, thus thrown on it, or perhaps raifed by the burfting of vulcanos from its bottom; and fomething altered from their original form and colour, by being wafhed and rounded by the motion of the waves, and by rolling againft one another, gave rife to an opinion in fome, that thefe were of another kind, and were different from thofe *pumices* found on the burning mountains, and that they were formed by the concretion of the froth of the fea. Many have fuppofed, that the authors who have favoured this opinion ranked the alcyonia among the bodies they call *pumices* fo formed; and Theophraftus has been very unjuftly cenfured of the fame fault, tho' not guilty of it. *Hill*'s Theophraftus, p. 48.

There are whole mountains in the principality of Heffe, which confift of rocks of the *pumice* ftone, as it is there vulgarly called. This is a fpungy and cavernous ftone, of a grey colour, and very much refembles the *pumices* in external appearance; but on examination, proves to be a very different fubftance, and there is not the leaft ground for fuppofing, that it owes its prefent appearance to the action of fire, as the common *pumices* thrown out of the burning mountains certainly do. It is very neceffary, in order to treat accurately of the nature of the *pumice*-ftone, to diftinguifh rightly between thefe ftones and fuch as have been burnt into their fpungy ftate. Yet this is generally neglected, and thefe are called *pumices* as well as the reft, and all are fuppofed to be of the fame origin.

PUMPING *at fea*, is ufually done by fpells, that is, by relieving the men with frefh ones, and counting how many ftrokes they *pump* each watch. By this means they know if the fhip be ftanch, or how her leaks increafe.

When all the water is drawn up, and there comes up nothing but wind and froth, they fay the *pump fucks*.

PUMPKIN. See the article PEPO.

PUNARU, in zoology, the name of a fmall fifh of the alauda kind. It has an oblong body, and a thick head, obtufe at the fnout. The mouth is fmall, and in the lower jaw there are only two oblong teeth, which are fharp and pointed like needles. The eyes ftand high in the head, the pupil is black, and the iris yellow; and over thefe there are two fhort red filaments. The gills are large, and have two oblong fins placed behind them. The back fin reaches from the head to the tail, and is prickly at the edge. The belly-fin reaches from the anus to the tail. The fkin and fins are all brown.

Befides this, there is another fpecies, variegated on its fides with lines of a dufky purple. Its jaws befet with very fmall teeth, and its fins not prickly. Both kinds are found among the rocks about Brafil, and fometimes get into the fhells of the larger fhell-fifh. *Marggrave*'s Hift. Brafil.

PUNAY, in natural hiftory, a name given by the people of the Philippine iflands to a very beautiful fpecies of turtle, common in their woods.

It is of the fize of a fmall parrot, and is of a fine green colour; but the extreme feathers of its wings are tipped with white, and the lower part of its belly is of a faffron colour. Its beak is yellow.

PUNCH (*Cycl.*)—PUNCH, in the manege, a well fet, well knit horfe, called in French *gouffaut*. He fhould be fhort-backed, and thick fhouldered, with a broad neck, and well lined with flefh.

PUNCTICULARIS *febris*, a name given by fome authors to a fever attended with fmall eruptions.

PUNCTURE (*Cycl.*)—Among the number of the moft fimple wounds are reckoned thofe which are made by *puncture*, or ftabbing on the external parts, and not penetrating to a very great depth. In thefe wounds, after the blood has been ftopped at the firft dreffing, by the application of dry lint, the common digeftive, or *linimentum Arcæi*, is to be fpread upon a pledget and applied once every day; or if the difcharge is but fmall, every other day, covering the dreffings with a plaifter and comprefs, and fecuring the whole with a proper bandage. At each dreffing, care muft be taken to remove every thing that will give way readily; the pus or fanies is to be gently wiped off with fine raggs; and unlefs a great difcharge of matter make it neceffary, too frequent dreffings do rather harm than good. The firft dreffings that have been applied, efpecially when there has been a flux of blood, fhould by no means be removed forcibly; but be left till they will fall off of themfelves, which they will do after a fuppuration is formed: and by this caution, much pain, and, perhaps, a frefh hæmorrhage, are avoided.

When a *puncture*, however, penetrates very deep, the cure is attended with many difficulties; efpecially if it is made perpendicularly down, and has no depending orifice: for, in this cafe, the blood and matter are eafily collected at the bottom, and protract the cure, and frequently form fiftulæ. To prevent thefe confequences, it will be proper to prefs the wound from the bottom upwards, to apply a comprefs toward th bottom of the wound externally, and to apply a bandage over all, which preffes much tighter upon the lower than upon the upper parts. If all this precaution, however, prove of no effect, which, indeed, is too often the cafe, it is the moft proper method to make a large opening at the bottom of the wound, before any fiftulæ are formed there. In order to make this opening to the greater advantage, it will be proper to get a particular fort of probe or needle, very blunt at top, and at the other end provided with a large eye, or hole, through which a linnen rag may be paffed. This probe is to be paffed to the bottom of the wound, and the blunt end of it preffed outwards toward the fkin, till you can feel it with a finger: when you can feel it, cut down upon it if you can fafely, and make a large opening; fpread the rag that you have run through the eye of the probe with fome vulnerary balfam, and draw it through the wound after the manner of a feton, and leave it there, dreffing up both the orifices with the fame balfam, and covering the whole with compreffes and the proper bandages. In every fucceeding dreffing, that part of the rag that is left out of the wound is to be fpread with frefh ointment, and the lower part drawn down till this takes place in the new wound. This method is to be continued till the wound is well cleanfed, the difcharge greatly diminifhed, and all in a readinefs to heal: the feton is then to be removed, and the wound healed as ufual. *Heifter*'s Surg. p. 35.

PUNICA, the *pomegranate*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the rofaceous kind, being compofed of feveral petals, arranged in a circular form. The cup is of the fhape of a bell, and divided into feveral fegments at the edges; this finally becomes a fruit of a roundifh figure, coronated at the end, and divided into many cells within, which contain many kernels full of juice, affixed to a placenta, and feparated from one another by very fine membranes: thefe contain feeds of an oblong figure.

The fpecies of *pomegranate*, enumerated by Mr. Tournefort, are thefe: 1. The common cultivated *pomegranate*. 2. The common wild *pomegranate*. 3. The cultivated *pomegranate*, with fweet fruit. 4. The cultivated *pomegranate*, with fruit of a middle tafte between fweet and four. 5. The large fruited *pomegranate*, with large, crifp, amathyftine kernels. 6. The great double-flowered *pomegranate*, or balauftine. 7. The *pomegranate* with a double variegated flower. 8. The *pomegranate* with fmall double flowers. And, 9. The low dwarf American *pomegranate*. *Tourn.* Inft. p. 636.

PUNICUS *lapis*, a name given by the writers of the middle ages to a ftone of a fpungy texture, the powder of which was good in difeafes of the eyes.

This feems to have been no other than the pumice, the writers of thefe times having been ftrangely incorrect in their orthography; and all the virtues afcribed to this ftone, as alfo the places where it was found, which are the Æolian iflands, &c. feeming to have been copied from Pliny's account of the pumice.

PUNK, in natural hiftory, the inward part of the excrefcence or exuberance of an oak. It is ufed by the Indians in Virginia for medicinal burning, as the Eaft Indians ufe moxa. Phil. Tranf. N°. 454, fect. 1. See MOXA.

PUPIL (*Cycl.*)—PUPIL *contracted*. The diftemper of the eye called by furgeons a *contraction of the pupil*, is fo total or clofe a contraction of that part as will not let it tranfmit light enough to the bottom of the eye, to enable the patient to fee objects diftinctly. Sometimes this diforder is from infancy, and fometimes it arifes from an intenfe inflammation of the eye, or other caufes.

The cure of this is extremely difficult; but Mr. Chefelden has invented a method by which he has often proved very fuccefsful in his attempts to relieve it. The method is this: the eyelids being held open by a fpeculum oculi, he takes a narrow fingle-edged fcalpell, or needle, almoft like that ufed in couching for a cataract, and paffing it through the fclerotica, as in couching, he afterwards thrufts it forward through the uvea or iris, and in extracting it cuts through the iris.

If the diforder is not accompanied with a cataract, it will be beft to cut through the iris in the middle; otherwife, when there is a cataract, the incifion fhould be made a little higher in the uvea, that the cataract may not obftruct the ingrefs of the rays of light. The cataracts that accompany this diforder are ufually very fmall, and fometimes their adhefion to the iris is fo firm, as to render it impracticable to couch or fupprefs them. *Heifter*'s Surg. p. 417.

PUPPETS, in natural hiftory, the name given by Swammerdam to the nymphæ of animals, which he diftinguifhes from the chryfalifes by this fimple name, calling thefe the *gilt puppets*, from their golden colour.

It has been a general diftinction eftablifhed by writers between the nymph and chryfalis, that in the former the limbs and lineaments of the future animal might be feen, but in the latter not. But Swammerdam has proved, that the lineaments of every trace, and every part of the animal, is to be feen under the

the chryfalis as well as under the nymph ftate, with proper attention in the examination, and that therefore the diftinction is founded on a very vague and uncertain bafis. The far greater part of the infect kingdom are hatched from the egg in the worm ftate, and become, after a time, changed into thefe chryfalifes and aureliæ; but fome are hatched perfect, and in their own form, from the egg. Among thofe which undergo the change into the chryfalis ftate, the principal diftinction is into worms that have legs, and worms that have not any. The breaft of thofe worms which have no feet is never changed at all, and among thofe worms which have many feet, the fix fore feet are never changed, but ferve the animal as well in its flying ftate as in its creeping one. The wings, the horns, the feet, &c. grow up under the fkin by degrees.

In all worms, of whatever kind, thefe parts may be diftinguifhed more or lefs plainly under the fkin, at the different times of their growth, in different degrees of forwardnefs. Even the frog may be thus traced, by proper care, in the tadpole, and all its changing from the tad-pole ftate to that of the perfect animal, is no other than as in the butterfly, the developing and unfolding its parts, as they require a proper age, confiftence, and maturity.

Mouffet, and other writers on infects, call the aurelia a feparate and peculiar thing, and exprefly neither an egg nor an animal. Harvey alfo miftakes the matter as grofly, in calling the aurelia an egg, and faying, that the bloodlefs animalcules are produced by transformation; but thefe are expreffions much to be lamented in the works of fuch great men, and have been the means of darkening and perplexing the knowledge of the aurelia ftate in infects, and muft be overthrown before any true judgment can be formed of that ftate.

All the change happening in the *puppets*, or nymphæ, which was fuppofed by Harvey to be the production of one animal from another, is in reality no more than the exfudation of a certain abundant moifture which leaves the animal dry, and all its parts firm and capable of expanding and extending themfelves, and bearing the weather.

Goedartius has alfo propagated another groundlefs error, which, by its confequences, tends to overthrow all the true knowledge of thefe changes. This is, that the caterpillar may change before its time, and that in this cafe it becomes a very different animal in the winged ftate. This tends wholly to overthrow the conftant and uniform law of nature, according to which, all the lineaments of the perfect animal are formed even in the egg, and have only to grow and enlarge in the worm and chryfalis ftate; and can therefore be fubject to no change in either.

What has led Geodartius into this error, was real obfervation, only not carried fo far as it fhould have been. In fome of the infects which fuffer the chryfalis ftate, the males are winged and the females not. In thefe the courfe and order of nature is as invariable as in the reft, all the males being of the winged, and all the females of the reptile kind; but this author, not knowing this great difference in the fexes, when he had been ufed to fee a winged creature come out of the chryfalis of a worm he knew very well, and found inftead of it a creeping animal without wings, fuppofed the creature, which was only of a different fex, to be of a different fpecies.

Some difference alfo is found in the fize of the fly produced from the chryfalis of the fame fpecies of caterpillar, according to its changing fooner or later into that ftate. All the difference, however, is, that if the caterpillar eats its fill firft, the fly is the larger and the fairer; and if it goes into the chryfalis earlier, then the fly is the lefs perfect: and of whatever fize the fly is when produced out of the chryfalis, in that it remains; for it can grow no more after it has paffed this latter change.

From the knowledge of the propagation of this fort of animal, this author goes up to that of larger creatures, and is firm in the opinion, that there is properly no fuch thing as generation at all; that all that our blindnefs calls fo, is only a fenfible production by the growing of parts at firft very minute. All the parts of the butterfly may be feen, by a proper infpection, in the caterpillar; and as to the imaginary tranfformation of the caterpillar into the chryfalis, it may be retarded and made to come on fo eafily, as to become the object of the fenfes, and finally ftopped in the progrefs, fo as to appear half caterpillar, half chryfalis. *Swammerdam*'s Hift. Infect.

PUPPIS OS, a name given by fome authors to the os frontis. The future in this bone is alfo called by many anatomifts the *futura puppis*.

PUPULÆ, a name ufed by fome to exprefs the extremities of the fingers.

PUR *autre vie*, in our law-books, is ufed where lands are held for the life of another.

PURCHASE-*book*, among traders, is the name given to a book which is a kind of journal, containing an account of all the purchafes made, or things bought in the day.

Purchafe, in the fea-language, is the fame as *draw in*: thus when they fay, *the capftan purchafes apace*, they only mean it draws in the cable apace; alfo when they cannot draw or hale in any thing with the tackle, they fay, *the tackle will not purchafe*.

PURETTA, a name given by fome writers to the common fhining black fand, ufed to ftrew over writing, and erroneoufly called by fome *fteel-duft*.

It is a natural mineral fubftance, found on the fhores near Genoa and in other places.

PURGATIVE (*Cycl.*)—We have had attempts of adjufting the dofes of *purgative* medicines fcientifically. Dr. Cockburn endeavoured at the folution of this problem; but, it is faid, on wrong principles. Dr. Balguy has alfo given us an effay on this fubject in the Med Eff. Edinb. Vol. IV. art 5.

He affumes, that part of the medicine is fpent on the firft paffages, where it acts as a ftimulus; and that the other part is carried into the blood, and has its effect there by thinning and rarifying it. This being premifed, 1ft. If the medicine acts only in the firft paffages, the dofe will be as the fize of the perfon into the conftitution. 2d. If the whole medicine paffes into the blood, the dofe will be as the fize into the fquare of the conftitution; and therefore, 3d. You are to dofe fo much of the medicine as is fpent on the ftomach and inteftines directly, as the conftitution; and fo much as is carried into the blood, as the fquare of the conftitution, and the fum into the perfon's fize, is the quantity required.

The fame rules hold in vomits. How far in either cafe the practice of phyfic may be thereby improved, we leave to the judgment of the learned. The folution of the problem fuppofes a great poftulatum, no lefs than the art of meafuring a perfon's conftitution!

PURGATION, *purgatio*, in rhetoric, is ufed for that kind of defence which takes place when the accufed perfon owns the fact, but denies that he did it with defign, or with any bad intention. *Voff.* Rhet. l. 1. p. 148.

PURIFICATION, in pharmacy. See TRYING.

PURPURA, the *purple-fifh*, in natural hiftory, the name of a genus of fhell-fifh, the characters of which are thefe: it is a univalve fhell, jagged and befet from head to tail with fpines, tubercles, umbos, or ftriæ. The mouth is fmall and roundifh; the tail is fhort, and ufually the bafe runs out into a long beak.

It has been ufual with moft authors to confound together the genera of the murex and *purpura*, and to ufe the words as fynonymous: but tho' there is fome external refemblance between many of the fhells of the two genera, yet they are eafily diftinguifhed by this, that the mouth of the *purpura* is lefs long, and is lefs dentated and alated than that of the murex. The body and the head of the fhells of this genus are not fo elevated as thofe of the murex kind, and are not covered with points or buttons at the mouth. If a fhell is therefore found to have a fmall, fmooth, and round mouth, and a body covered with undulated leaves, as it were, like thofe of favory or endive, and fometimes with long points, and its tail, whether long or fhort, be hollowed and fomewhat bent, this may be called a *purpura* and not a murex.

The antients diftinguifhed three kinds of *purpura*, one which had a long and crooked tail, made hollow like a tube or pipe; a fecond which had either no tail at all, or at the moft a very fhort one; and a third which had no fpiral head, or, as we fhould exprefs it, no clavicle.

On examining the whole family of the *purpuræ*, we may diftinguifh four remarkable fpecific differences among them. The firft of thefe comprehends thofe *purpuræ* which have the body of the fhell garnifhed with a fort of undulated foliage in clouded ridges, and have a fhort and crooked tail. The fecond comprehends thofe which have the body of the fhell covered with acute points, and have a long tail. The third comprehends thofe which have as long a tail as the former, but have a fmooth body, or at the utmoft have only a few flight protuberances and wrinkles on it. And the fourth takes in thofe which are fmall, and have an elevated clavicle, a fhort crooked tail, and the body of which is covered either with flender fpines or hairs. See Tab. of Shells, N°. 14.

This fpecies of fifh, as well as the murex, ferved among the antients to dye the fine purple colour they were fo fond of, and fome of the buccina have been of late found to have the fame juice. The *purpura* and murex are both fifhed up in great plenty in the gulph of Tarentum; but the fmall quantity of the coloured juice which each fifh contains, and the neceffity of ufing it before the animal dies, makes it impoffible to bring it to any regular article of traffick. The antients ufed this colour only on cotton and woollen ftuffs, whereas our cochineal, which was unknown to the antients, ftrikes equally well on filks and ftuffs.

The *purpura* lives on other fifh. It ufually hides itfelf at a fmall depth in the fand, fometimes even in frefh-water rivers, and as it lies hid, it thrufts up a pointed tongue, which wounds and kills any thing that comes over it. We frequently find fea-fhells with round holes bored through them, as regularly as if made with a boring inftrument: thefe are generally allowed to be made by the tongue of the *purpura*, in order to its feeding on the fifh within.

The *purpura* has two horns like that of a fnail; and Fabius Columna fays, that they have eyes in thefe, not placed at the ends, as in the fnail, but in the middle of each horn.

Of the ramose, or branched *purpuræ*, with short tails, we have the following species preserved in cabinets. 1. The rough *purpura*, with a flesh-coloured lip, armed with three rows of branches. 2. The yellow *purpura*, with three rows of high branches. 3. The tribulus, or whitish *purpura*, with three rows of less jagged branches. 4. The fine armed *purpura*, with the branches jagged in the manner of the foot of a toad, with a distinct clavicle. 5. The less rough *purpura*, with six rows of branches. 6. The curled lettuce *purpura*, jagged from the head to the base, and having six rows of branches.

Of the spinose *purpuræ* with long tails, we have these: 1. The great spinose *purpura*, with very long spines. 2. The small spinose *purpura*, with three rows of shorter spines. 3. The small rough *purpura*.

Of the *purpuræ* covered with tubera, having a long beak and long tail, we have the following: 1. The woodcock *purpura*, with a long tail and no spines. 2. The less spotted woodcock *purpura*. 3. The small brown woodcock *purpura*.

Of the thick costated, or ribbed *purpuræ*, with crooked beaks, we have the following species: 1. The marble costated and tuberous *purpura*, with blue fasciæ. 2. The spinose marbled *purpura*.

Of the hairy *purpuræ*, with long clavicles, we have the following species: 1. The grey *purpura*, with three rows of spin s or hairs, with an erected clavicle and strait beak. 2. The crooked beaked hairy *purpura*, with several setose fimbriæ.

Of the thin oculated *purpuræ*, with compressed clavicles and short beaks, we have the following species: 1. The sea-porcupine, or oculated *purpura*. 2. The porphyry *purpura*. Hist. Nat. Eclairc. p. 298.

The *purpura* is a shell-fish very well known, and has been known also in almost all times to afford a purple liquor; but as there has been no method discovered of bringing this liquor into use in dying, the fish has been neglected, and its juice never attempted to be brought into use.

The juice which gives this beautiful purple colour is, while it remains in the body of the animal, and while that is in health, wholly white; but no sooner is it exposed to the sun, than it begins to change colour, and in less than five minutes goes through the several changes of pale green, yellowish, and a beautiful emerald green: after this it becomes of a deeper and duskier green, then bluish, reddish, and finally a deep and very beautiful purple. Sometimes the juice is found naturally green in the animal; this is probably from the creature's being in a diseased state: but when it is naturally thus, it immediately becomes red, and afterwards purple, on being exposed to the sun, its several preceding changes seeming to have been made already in the body of the animal.

If a piece of linnen be rubbed over with this juice, and part of it exposed to the sun, part not, that only will turn red which is so exposed, the other remaining green without any alteration; and it is observed, that the stronger the sun shines, the quicker the change appears, and probably the colour is in proportion also the more beautiful and lively. And it is very remarkable, that if a needle, or any other opake body, be laid upon the linnen which is yet green, and is to become red on being exposed to the sun; after such an exposure the whole shall be changed red or purple, excepting only that small spot which is covered by the needle, which will still remain green.

A plate of glass, tho' it be three inches thick, will not prevent the colour from changing purple by being laid over it; but the thinnest piece of metal will keep it wholly green. The one being opake, and the other pellucid, are evidently the only reasons for this difference.

If the coloured linnen be successively covered by three pieces of paper, the one blacked with ink, the other in its natural state, and the third rubbed over with oil, it will change colour on being exposed to the sun in different degrees; and that exactly in proportion to the degree of transparence in each of the papers: most of all in that which was covered with the oiled paper, something less than that covered by the paper in its natural state, and least of all in that which was covered with the blacked paper, as that is least transparent.

The common heat of a fire, or that of a red hot iron, produce no change at all in the colour when green. The vapour of burning sulphur produces a little; but the green which had not changed to purple by these experiments, immediately changed to it on being exposed to the rays of the sun.

These experiments were all made in the months of January and February, by Mr. Du Hamel, in Provence; and the sun having power to change the colour so speedily there in these cold months, probably in a warmer climate or season the air would have been sufficient for the purpose, without the open sun; since it seems, from experiment, that both the solar rays, and the light alone in a cloudy day, can act upon this colour. The light and heat of the sun both act on this colour: light is always sufficient to produce the effect; but the heat may easily be too great, or too little, and to do the whole in perfection it must be at a certain middle degree.

This beautiful purple, if it can ever be brought into use in dying, will have one very great advantage from its viscosity. The pieces of cloth that had been stained by it retained their colour, in spite of several boilings in different liquors, which Mr. Du Hamel made them pass through; and the colour, on examination, was found not to be superficial, but penetrated the whole body of the stuff which was tinged by it. There are many inconveniences which must naturally attend the use of this substance as a dye, but they may, perhaps, all be got over by care and application. It is very certain, that it is of too viscid a nature easily to penetrate many substances; but it is also certain, that this might be obviated by dissolving it in some proper liquor. It appears very plainly, that the antients had a method of thus dissolving their purple; but we neither know what was their purple, nor what was its dissolvent; nor, which would be of much more consequence to us at present, what is the proper dissolvent for our own. Mem. Acad. Scien. Par. 1736.

Persian PURPURA, the same with the Persian-shell, a species of dolium. See DOLIUM.

PURPUREA *febris*, the *purple fever*, in medicine, the name given by authors to a species of *fever*, called also by some a *miliary fever*.

It is an acute, continual, and exanthematous *fever*, in which nature seems to be endeavouring to drive out the subtle morbific matter to the surface of the body, by increasing her secretory and excretory motions. *Junker's* Consp. Med. p. 325.

This *fever* is divided into two kinds; of the which, one is called *purpura rubra*, or the *red purple fever*; and the other by a very odd form of expression, the *purpura alba*, or *white purple fever*.

The white *purple fever* is usually malignant; it is easily complicated with the petechial *fevers*, and in some places has of late years been found often to affect lying-in women.

The red *purpura* is much more benign and mild than this, and, indeed, often is attended with no danger.

These two species of *purpura* seem to differ as much as the small-pox and measles do from one another, the white *fever* of this kind being usually as much more fatal than the red, as the small-pox is more fatal than the measles; but as there are cases in which the small-pox is mild and benign, and the measles are sometimes dangerous, so in these diseases, out of the natural course, the white is sometimes mild, and attended but with a slight *fever*, while the red is fatal, and attended with a very high one. As the small-pox also has white pustules, and the measles only protuberances on the skin; so the white *purple fever* has also regular white pustules, while the red has only such protuberances as those of the measles. *Junk's* Consp. Med. p. 327.

Signs of these diseases. The white kind seizes the patient with a general shivering and coldness, and a straitness of the præcordia, with great anxiety of mind, and afterwards shews itself in alternate changes of heat and cold; and before the appearance of the eruptions, the patients are worse in respect of their anxiety and other symptoms, and complain of a troublesome itching under the skin. The pustules usually first appear on the fourth day, sometimes later; and at their approach, there is first perceived a general redness of the skin, and after this the redness is collected into spots, in the middle of each of which there appears a white pustule; and these are often so copiously spread over the body, that they almost touch one another. These pustules are pellucid, and contain only a clear water, and their eruption is usually attended with an acute fever; when these pustules have stood four days, they dry away, and the places appear scaly, and the disease terminates. Sometimes in people of humid habits, and such as have no *fever*, these pustules sweat out a white water.

The red *purple fever* seizes the patient in nearly the same way with the white, that is, with shiverings and heat succeeding one another. It is also attended with a tension and pain in the back, and with a straitness of the breast and a cough. The *purple* eruptions appear on the fourth, or on the seventh day, or later even than that, in form of small protuberances, like millet-seeds; and are attended at the time of their eruption, with an itching within the skin: the *fever* is not violent, and the sweat is copious, and of an ill smell. In some cases this disease is attended with no *fever* at all, and people go about their business with it, only complaining of an itching all over them. Some have violent pains of the head at the time, and are sleepy and anxious they know not why; but these symptoms usually go off as soon as the eruptions appear properly: these remain fully out a few days, and then die away of themselves, and the person finds himself as well as before.

The *purple fever* of both kinds seems to have been more frequent of late than in the times of the earlier writers on medicine. The white kind in particular, some years ago, was in a manner epidemic in Saxony, and carried off great numbers, and particularly seized the lying-in women. Wherever the petechial *fevers* are frequent, there the white *purple fever* is usually also common. It often also mixes itself with the small pox, and makes the case always greatly worse, and all the symptoms more violent. The red *purple fever* is most frequent with young men, and such as lead sedentary lives, and are subject to violent passions; labouring people are scarce ever found affected with this disease. Among women, those of tenderer constitutions are most subject to it; and especially such

as have been before subject to hysteric complaints. And the persons most subject of all others to it, are those of both sexes who live at ease and within doors, and by this means always are sending off the humours to the surface of the body.

Causes of it. These are, a bad quality in the air, contagion from persons who have the disease, the driving back of sweats, and even the forcing them too violently by hot medicines; this too often happens to women in child-bed, and to persons in petechial *fevers*. To these are to be added also, the curing the rheumatic and catarrhal disorders by a too cold regimen and method, and an omission of habitual bleedings, or by suppression of the menses, or discharges by the hæmorrhoidal veins.

Prognosticks in it. The going back of the eruptions in the white *purpura* is very often fatal, and in the mildest circumstances is usually attended with aphthæ, alienations of the mind, and terrible anxieties; and, if by means of medicines, the eruptions appear again, and yet the symptoms occasioned by their going in do not disappear, there is great reason to suspect danger. The white *purpura* attending the petechial *fever* is very dangerous when the eruptions appear on the fourth day, but is less so when they appear later. The white *purpura*, when not attended with a *fever*, is less dangerous than otherwise; but it is usually attended with terrible anxieties of mind, and with spastic motions.

The red *purpura*, when the eruptions are struck back, is not attended with such sudden danger as the white; but people usually have some convulsive motions attending it, and a great languor and debility of motion, and sometimes with inflammations of the fauces, and with dangerous quinseys; sometimes with a dry cough, sometimes with a heat of urine, or with arthritic complaints, or a spurious pleurisy, or a hemicrania; but all these symptoms go off as soon as the eruptions appear again.

Method of cure. This is to be the same both in the red and the white *purpura*, and is not different from that in other inflammatory *fevers*, namely, a gentle but continual perspiration must be kept up, and this alone will often cure the disease. On the days before the eruption of the spots, powders are to be given of nitre, diaphoretic antimony, and the absorbents, as crabs-eyes, and the like; and when the eruptions are out, which usually happens on the fourth day, the same powders must be given interchangeably, with gentle sudorific draughts, from all which, fumitory water, however, is to be carefully excluded. This method is to be continued, only giving the doses less frequently in the decline of the disease; and when it is wholly gone off, gentle purges, with some mercurial admixture, are to be given, thoroughly to cleanse the primæ viæ; and the patient is by degrees to be hardened to the air. It is to be observed, that all irritations of the bowels are as bad in these cases as in the small-pox or measles, and that even the use of the most gentle clysters is scarce to be allowed. Great care is to be taken that no cold air be admitted to the patient during the time the eruptions are out, and he should not be removed, nor have the bed made in all that time. People who are often subject to returns of the red or white *purpura*, would be right to use cupping with scarification frequently, by way of prevention; and when the cause of the disease is the suppression of some habitual evacuation, great care is to be taken to supply the place of that by bleedings, if it cannot be recalled in the accustomed way. This is to be done at different times, to prevent relapses; and in general, a method of using gentle exercise, so as to promote a moderate sweat, is greatly preferable to the method used by some of cloathing too warm, which rather promotes the disease by inviting the humors to the surface. *Junker's* Consp. Med. p. 329.

PURPURINA, a name used by Caneparius, and some other authors, for the *aurum mosaicum*, or *aurum musivum* of the shops, the present preparation of which differs from that of that author only in the proportions of the ingredients. *Pemberton's* Lond. Disp. p. 221. See AURUM *musivum*.

PURPURISSUS, in the antient writers, both Greek and Roman, the name of a compound colour or fucus of a fine purplish red, used to paint womens cheeks.

It seems by the composition to have been somewhat like our rose-pink, as it is called by the colourmen. It was made of the *creta argentaria*, or fine white kind of chalk, dissolved in a strong purple tincture of some of the roots or woods which dyed red; and when the coarser part was subsided to the bottom of the vessel, the liquor, while yet thick, was poured off into another vessel; and what subsided from this, which was as fine as flour, was of a beautiful pale purple, and was the *purpurissus* saved for use.

PURSE (*Cycl*)—PURSE, in the Turkish dominions, is a term appropriated to a certain sum of money. When the Turks speak of large sums, they always count by *purses*. In this, however, there is some difference; for the *purse* in Egypt is twenty-five thousand medines, and in other parts of Turky it is only twenty thousand. *Pocock's* Egypt. p. 175.

PURSLAIN, in botany. See PORTULACA.

PUS (*Cycl*)—A very small portion of *pus* absorbed into the blood-vessels, raises a putrid fever as certainly as yest does a fermentation in wort. This fever is not owing to its stimulating the solids to quicker and greater vibrations, but to its increasing the intestine motion and accelerating the animal process, hastening the change of the juices to that subtle acrid state which renders them unfit to be retained in the body, and disposes them to run off in colliquative evacuations, such as sweating and purging, which constantly attend these putrid or hectic fevers, or rising to internal ulcers. Med. Ess. Edinb. Vol V. art. 77. See PUTREFACTION.

When *pus* is laudable and mild, it is one of the most powerful digesters, suppurants, and incarners; when it stagnates too long, or when the liquors and vessels are faulty, it may become an acrid, stimulating, eroding sanies; when absorbed into the blood, it affects all the liquors, stimulates the vessels, and is capable of producing violent disorders.

PUSHERS, a name given to Canary birds when new flown. See BRANCHER, CANARY, and PASSERES *Canariensis*.

PUSILLATUM, a word used by some medical writers to express a coarse powder, or any medicinal substance, beat into small pieces for infusion, or the like purposes.

PUSU, in botany, the name of a famous plant growing in China, and greatly esteemed there. This and the ginseng these people a long time kept to themselves; but at length it was discovered, that the one was esteemed a certain prolonger of life, and the other a preservative against all diseases.

They, in their manner of speaking, say, that the *pusu* gives immortality: we have not been so happy to obtain any of this famous plant for the trial, but the ginseng having been brought over, and found not to possess those great virtues they ascribe to it, and the people in China, who are possessed of the *pusu*, dying, as well as those who have it not, we find, that the virtues of both are so greatly exaggerated by the Eastern dialect, that there is not much to be expected from them. *Redi's* Exper.

PUT, in the manege, called in French *mettre*, is used for the breaking or managing of a horse: thus,

To put a horse to corvets, or caprioles, is to teach him those parts of the manege.

To put a horse upon his haunches, called in French *asseoir*, is to make him bend them handsomely in galloping in the manege, or upon a stop See HAUNCHES.

To put a horse to the walk, trot, or gallop, is to make him walk, trot, or gallop.

To put a horse upon the button. See BUTTON.

PUTEAL, among the Romans, a small kind of edifice, raised in the place where a thunder-bolt had fallen. Mem. Acad. Inscript. Vol. III. p. 85, seq. See BIDENTAL.

PUTICULI, among the Romans, ditches or holes in the earth, a little without the Esquiline gate, in which the poorer sort of people were buried. *Pitisc.* in voc.

PUTORIUS, in zoology, the name by which authors call the polecat; a creature of the weasel kind, but larger than the common weasel, and of a blackish colour, and remarkable for its stinking smell.

The whole circumference of the face is white, at the extremity of the angles of the mouth there begins a broad line of a yellowish hue, which surrounds the head, and is white in several parts. Its long hairs are black, its short ones yellowish; and the throat, the feet, and the tail, are blacker than any other part of the body. The upper jaws stand out a little beyond the lower. The ears are broad and short, and are fringed, as it were, with white. Its stink is occasioned by an extremely fetid matter, secreted by two glands, which it has in common with all the creatures of this kind, within the anus.

It feeds on flesh, frequently stealing hens and other poultry, and sometimes contenting itself with their eggs. *Ray's* Syn. Quad. p. 199.

PUTORIUS *serpens*, in zoology, a name given by some to that species of serpent called by others *dryinus*. See DRYINUS.

PUTREFACTION (*Cycl*)—In *putrefaction* there is a great intestine motion; when carried to a height, and when the *putrefying* substance is much compressed, it is accompanied with heat and smoke, and sometimes flame. Air is necessary to it; and the visible texture of the *putrifying* mass is changed.

Putrefaction is the most subtle of all dissolvents. It effectually disjoins and separates all the component parts of *putrifying* bodies, except sea-salt. In this powerful solution, the intestine action of the minute particles of bodies creates, collects, or is by some way or other the cause and means of heat.

The fluids of the human body are much disposed to *putrefaction*, and out of the body become highly *putrid*, even in cool air, and without any stirring or agitation; and our blood and some of our juices, out of the circulation, but within the body, change to *putrid* matter.

The changes wrought in bodies by *putrefaction*, are no where more remarkable than in the *putrefaction* of vegetable substances, which by means of this change are brought nearly into the condition and nature of animal substances.

To prove this by an easy experiment, take a large quantity of cabbage-leaves, and press them hard down with weights in an open tub, with holes bored in its side; set them in a warm place, and the leaves will soon conceive a heat in the middle, and at length the whole, or nearly the whole, will be converted into a soft pappy substance. This substance distilled in a glass retort, yields the same kind of volatile salt and oil as

animal subſtances do: neither is it particular to this plant, but all equally do this; the acid and the alkaline, the ſweet and the bitter, the aſtringent and emolient. Hence we may learn, how it is that nature, in our bodies, converts vegetable into animal ſubſtances; and it is very remarkable, that not a grain of fixed ſalt can be procured from this *putrified* maſs. *Shaw's* Lect. p. 134.

PUTREFACTION *of water*. It is ſaid to be the peculiar quality of the Thames water, that it will ſtink and yet be wholeſome; and after this will recover itſelf again. Many ſailors have been obliged to drink it ſtinking, ſo that they held their noſes while they poured it down their throats, yet no ſickneſs enſued from it. It generates a ſort of ſpirit alſo in this ſtinking ſtate, which will take fire at the approach of a lighted candle as if ſpirit of wine were touched by the ſame.

PUTTOCKS, or PUTTOCK-*ſhrouds*, in a ſhip, are ſmall ſhrouds which go from the ſhrouds of the main-maſt, fore-maſt, and mizen-maſt, to the top-maſt ſhrouds; and if there be any top-gallant-maſts, there are *puttocks* to go from the top-maſt ſhrouds into theſe. Theſe *puttocks* are at the bottom ſeized to a ſtaff, or to ſome rope which is ſeized to a plate of iron, or to a dead-man's eye, to which the lanniards of the fore-maſt ſhrouds do come.

PUWAKHAGA, in botany, the name by which ſome authors call the faufel-tree, of whoſe fruit the expreſſed juice called *terra Japonica*, or Japan earth, is made. *Herm.* Muſ. Zeyl. p. 51.

PYANEPSION, Πυανεψιων, in the Athenian chronology, a month of thirty days, in which the feſtival *pianepſia* was celebrated. *Potter*, Archæol. Græc. T. 1. p. 464. See the article PYANEPSIA, *Cycl.*

PYCIELT, in botany, a name given by Hernandez, and ſome other authors, to a peculiar ſpecies of tobacco, diſtinguiſhed by Mr. Tournefort by the name of *nicotiana major lato et rotundo folio*, the broad roundiſh leaved great tobacco. See the article NICOTIANA.

PYCNI, πυκνοι, in the antient muſic, was uſed for ſuch ſounds or chords of a tetrachord as might enter the ſpiſſum, or πυκνον.

Theſe were the hypatæ [a], the parypatæ [b], and the lichani [c], of the ſeveral tetrachords. The hypatæ were called *barypycni*, βαρυπυκνοι; the parypatæ *meſopycni*, μεσοπυκνοι; and the lichani *oxypycni*, ὀξυπυκνοι: becauſe the firſt were the loweſt notes; the ſecond, the middle notes; and the third, the higheſt of the ſpiſſum [d]. Such chords as could never enter the ſpiſſum were called *apycni*, απυκνοι. [[a] ὑπατοειδεις. [b] παρυπατοειδεις. [c] λιχανοειδεις. [d] *Wallis's* Append. ad Ptolem. Harm. p. 165.]

Hence in the Greek ſcale or diagram [a], containing eighteen chords, there were five *barypycni*, as many *meſopycni*, and an equal number of *oxypycni*, together with three *apycni*. The *apycni* and *barypycni* were ſtabiles or fixed chords; but the *meſopycni* and *oxypycni* were moveable, or mobiles [b]. [[a] See DIAGRAM. [b] *Wallis* ibid. p. 165, 166.]

PYCNON, πυκνον, in the antient muſic. See SPISSUM.

PYE, in mechanics. See the article CRABB.

PYGAIA, in the materia medica, a name by which ſome authors have called the ipecacuanha, or vomiting Indian-root. *De Laet* Ind Occid. 566. *Purchas.* Pilgr. Vol. IV. p. 1311.

PYGARGITES, in natural hiſtory, a name given by Pliny and ſome other of the old writers to the eagle-ſtone, when it was variegated with white, in the manner of the tail of the eagle called *pygargus*.

Some have called this ſtone *pygarus*, and others have applied the name to a ſtone very different from the aetites, and only reſembling the colour of the eagle. From hence it has happened, that two very different ſtones have been confounded together; but the virtues of both being merely ideal and imaginary, the world is not greatly the worſe for the want of the neceſſary diſtinctions.

PYGARGUS, a ſpecies of eagle, called alſo by ſome authors *albicilla*, and *ilianularia*.

It is a large and fierce bird, of the ſize of a common turkey. Its beak is yellow, and covered with a yellow membrane at its baſe. It has large hazel-coloured eyes. Its feet are yellow, and its claws extremely ſtrong and ſharp. The head is white, and there are no feathers, but ſome fine hairs between the eyes and noſtrils. The upper part of the neck is of a reddiſh brown, and the rump black: all the body beſides this is of an obſcure ruſt colour, and its wings are partly black, partly grey. Its tail is long, and the upper half of it is white, and the reſt black. It is from this white part that it has its name *albicilla*.

Authors who have written on this ſubject ſeem not all agreed to call the ſame bird by this name. The *pygargus* of Aldrovand ſeems different from this, and the *pygargus prior* of Bellonius ſeems no other than the male of that kind of hawk called in Engliſh the *hen-harrier*. *Willughby's* Ornithol. p. 31

PYGARGUS *accipiter*, in zoology, a name by which many authors have called the ſubbuteo, a bird of the hawk kind; the male of which is called in Engliſh the *hen-harrier*, and the female the *ringtail*. *Ray's* Ornithol. p. 40. See HENHARRIER and RINGTAIL.

PYKER, or PYCAR, in our writers, a ſmall ſhip or herring-boat. 31 Edw. III. c. 2. *Blount. Cowel.*

PYLÆA, Πυλαια, in antiquity, a name given to the aſſembly of the Amphictyons, as well when they met at Delphi as at Thermopylæ. The concourſe of people at theſe aſſemblies was ſo great, that the term *pylæa* came to be uſed for any very numerous aſſembly, or croud of people. Mem. Acad. Inſcr. Vol. IV. pp. 287, 290.

PYLAGORE, Πυλαγορες, in antiquity, a name given to the Amphictyons, becauſe they aſſembled at Thermopylæ, or Pylæ. See AMPHICTYONS, *Cycl.* and *Suppl.*

PYLORUS (*Cycl.*)—Kerkring gives us an account from his own knowledge of the entire ſtoppage of this part, by a Dutch ſtiver accidentally ſwallowed, the conſequence of which was the death of the patient in a few days. On the other hand, he mentions an inſtance of another perſon's ſwallowing a copper coin, which without any other effect than violent nauſeas and ſickneſs, was, at the end of about a month, diſcharged by purges; but ſo corroded by the juices of the ſtomach, that it was ſcarce to be known, all the letters and marks being eaten down to the ſame common ſurface on both ſides. *Kerkring's* Specileg. Anat.

PYNANG, in botany, a name by which ſome authors call the faufel, or areca tree; a kind of palm, from the expreſſed juice of which the drug commonly, but improperly, called *Japan-earth* is made. *Bont.* p. 90.

PYRACANTHA, in botany, a name given by ſome authors to the lycium, or box-thorn.

PYRALIS, the *fire-fly*, a name given by authors to a ſuppoſed inſect, which they ſay is produced in the violent fires of the glaſs and metal furnaces. Plin. l. 2. c. 36.

PYRAMIDALIS (*Cycl.*)—PYRAMIDALES *abdominis*. Theſe are called *ſuccenturiati* by Fallopius; they are ſituated on the lower part of the recti, and ſeem only a portion or appendix of it. They are partly incloſed within the vagina of the recti, running cloſe by each other along the linea alba, to which they are fixed at different diſtances by oblique tendinous indentations, the uppermoſt of which was ſometimes very long.

When theſe muſcles are wanting, the lower extremities of the recti are always thicker than uſual: often there is only one found, and ſometimes, tho' rarely, three. *Winſlow's* Anat. p. 168.

PYRAMIDALIS *oculorum*, in anatomy, a name given by Molinet and ſome others to one of the muſcles of the face, called by Douglaſs and Cooper *aperiens palpebram*, and by Albinus *levator palpebræ ſuperioris*.

PYRÆIA, or PYRETHEA, among the Eaſtern nations of antiquity, were great incloſures uncovered, and dedicated to the ſun, in which a perpetual fire was kept up in honour of this luminary, which was worſhipped by moſt of them. *Calmet.* Dict. Bibl. See CHAMANIM.

PYRENE, in natural hiſtory, the name of a ſtone found always in the ſhape of the ſtone of an olive. It is of the lapis judaicus kind, being no other than the petrified ſpine of ſome ſpecies of echinites. See ECHINUS *marinus*.

PYRETHRUM (*Cycl.*)—PYRETHRUM, in the materia medica, a root of which the druggiſts ſell us indiſcriminately two kinds; the one the root of a corymbiferous plant, called by authors *pyrethrum flore Bellidis*, or the daiſy-flowered pellitory of Spain; the other, the *pyrethrum umbelliferum*, or umbelliferous pellitory: and it is a diſpute among the learned, which of the two is the genuine and proper kind. The deſcription left us of it by Dioſcorides, as it is differently written, ſerving as well to prove the one ſo as the other.

The roots of the daiſy-flowered pellitory are what we moſt frequently meet with. They are of three or four inches long, of the thickneſs of one's little finger, greyiſh and wrinkled without, and whitiſh within, and of an acrid and burning taſte. Thoſe of the umbelliferous pellitory are of the ſame length, but ſomewhat thinner, of a browniſh grey without, and white within, and are furniſhed with a ſort of beard at top, ſomewhat like the roots of the meum. It is of an acrid taſte, and much reſembles the other in its virtues. They are both uſed in the tooth-ach, and are preſcribed by ſome in diſeaſes of the head and nerves, and are found to be diuretic and violently ſudorific, but they are very ſeldom given.

PYRGUS, among the Romans, a dice-box of the ſhape of a medius, open above, and having a great many ſhelves or partitions within it; ſo that when the dice were thrown into it out of the frittillum, they were thereby overturned many times before they could reach the bottom, in which there was an opening for them to fall through upon the table. *Pitiſc.* in voc. See FRITTILLUM.

PYRHOPOECILOS, in the natural hiſtory of the antients, a ſtone ſo called from its having a great many ſpots of the colour of fire. *Pitiſc.* in voc.

PYRIATERION, a word uſed by the antients to expreſs a ſweating room.

PYRIATOS, a word uſed by ſome authors to expreſs a brick when heated, in order to be applied to the body wrapped up in a cloth by way of a dry fomentation.

PYRICAUSTUM, a word uſed by medical writers to expreſs a burn or ſcald.

PYRICUBIUM, in natural hiſtory, the name of a genus of foſſile bodies, uſually comprehended, with many others of very different figure and ſtructure, under the general name *pyrites*. See Tab. of Foſſils, Claſs 5.

The diftinguifhing characters of the *pyricubia* are thefe: they are compound, inflammable, metallic bodies, of a cubic figure, or refembling a die, being compofed of fix fides.

Of this genus there are only two known fpecies: 1. The great *pyricubium*, of a foliaceous ftructure; and, 2. The fmaller folid *pyricubium*. See Tab. of Foff. Clafs 5.

The firft of thefe is a very elegant foffil, and is fo regularly fhaped, and fo highly polifhed by nature, that it has been often fuppofed to be wrought by art. It is but moderately hard, but is very heavy, and is of a foliaceous ftructure. It is exactly of the figure of a die, being compofed of fix regular fides, placed at right angles; but tho' ever thus regular in fhape, it is not at all fo in fize: the moft common fpecimens of it are about a third of an inch in diameter; but it is found much larger, even to three inches, and fo fmall as to the tenth of an inch. It is perfectly polifhed and fmooth on all its furfaces, and is of a very beautiful whitifh green, with a faint admixture of yellow. It is found in the German and Hungarian mines, and in the Eaft Indies.

The fecond fort, or the fmall folid *pyricubium*, is a foffil of much lefs beauty, tho' equally regular in its fhape and appearance. It is very heavy, and extremely firm and hard, and is not of a foliaceous or flaky ftructure; but of one regular and uniform mafs, and when broken appears very bright and gloffy. It is ever found in the regular form of a cube, or regular folid body, made up of fix flat fides placed at right angles. Its ufual fize is about the eighth of an inch diameter, but it is found fmaller than a pin's head, and fometimes fo large as to be near an inch. It is perfectly fmooth on all its furfaces, and is naturally of a pale yellowifh green, and as bright on the outfide as within; but very often it is found of a ferruginous or dufky furface, owing to a fort of rufting, which is an accident to which the feveral fpecies of naturally bright pyritæ are moft of them alfo fubject.

It is very common in Germany and Italy, and in fome parts of America, as alfo in our own country. With us it is commonly found immerfed in flate, fuch as we cover houfes with; but in Germany and other places it is ufually found loofe among the earth of mountains. With us it is ufually of a bright furface, in Germany it is more frequently dufky. *Hill's* Hift. of Foff. p. 619.

PYRIFORMIS (*Cycl.*)—This is alfo called *pyramidalis*, and is a fmall oblong mufcle, of the figure of a flat pear, or *pyramid*, whence it has its names.

It is fituated almoft tranfverfely between the os facrum and ifchium, being covered and hid by the firft two glutæi. It is fixed to the interior lateral part of the os facrum by flefhy fibres, and to the neighbouring part of the anterior or concave fide of that bone, by three digitations lying between the anterior holes. It is alfo fixed by a fmall infertion to the ligamentum facro-fciaticum, and edge of the great finus of the os ilium. From thence it runs tranfverfely toward the joint of the hip, its fibres contracting in breadth; it terminates in a fhort tendon, which is inferted in the middle of the internal labium of the upper edge of the great trochanter, by two or three branches. The upper part of this tendon receives feveral fibres from the glutæus medius, and its lower part is united to the gemellus fuperior, and tendon of the obturator internus. Sometimes there are two *pyriformes*, feparated only by the nervus fciaticus. *Winflow's* Anat. 209.

PYRIPHLEGES, a word ufed by the old writers in medicine to exprefs a perfon labouring under an extreme degree of a febrile heat.

PYRIPLACIS, in natural hiftory, the name of a genus of pyritæ, the characters of which are thefe: they are compound, inflammable, metallic bodies, found in loofe detached maffes of a fimple and uniform, not ftriated internal ftructure, and are covered with an inveftient coat or cruft.

Of this genus of foffils there are three known fpecies: 1. A flatted kind, with a fcabrous coat. 2. A globofe one, with a cracked and furrowed coat. And 3. A flatted one, with a very thick, brownifh-white cruft. See Tab. of Foff. Clafs 5.

The firft of thefe is a dufky brownifh-green mafs, furrounded and every way covered by a ferruginous coat, of the thicknefs of a fhilling or more, which is rendered very rough and fcabrous, by having received multitudes of fmall pebbles and particles of fand into its fubftance while yet moift, which are become firmly bedded in it, and make a part of its fubftance. This is common in the gravel-pits about London.

The fecond is of an orbicular figure, and is of a very coarfe ftructure, being compofed of vifible granules, and is of a pale yet dufky green colour. It is covered with a brownifh yellow or ferrugineous coat, of the thicknefs of half a crown, or fometimes much more. This is ufually fomewhat irregularly raifed in tubercles on the furface, which are divided by a fort of fine lines: thefe are truly fo many cracks in the fuperficies, all which, when the body has been fome time expofed to a damp air, fly more afunder at their edges, and become deeper, opening into the body of the mafs. This fpecies is found of all the intermediate fizes between an ounce and eight or ten pounds in weight. It is very common in the chalk-pits of Kent, and in many other parts of the kingdom; and tho' moft frequently found in chalk, yet is fometimes met with among gravel, or lying loofe upon the furface.

The third is a very fingular fpecies, yet from its unpromifing appearance has been overlooked by all the enquirers into thefe fubjects; having never been defcribed in the writings, nor preferved in the mufeums of the late collectors of foffils. It is very hard, and moderately heavy, and is ufually of a flatted, orbicular, or oval figure; and its moft frequent fize is between two and three inches in diameter. It is of an irregular, uneven, and rough furface, full of fmall prominences, very harfh and rough to the touch, and looks merely like a lump of greyifh hard clay. When broken, it is found, however, to confift of a nucleus of the fame fhape with the whole body, and every way equally furrounded with a cruft of a thicknefs equal to its whole diameter, or nearly fo.

The nucleus is of a deep and dufky brownifh-green colour, and of a plain fimple ftructure; being compofed of no vifible moleculæ. The cruft is of a pale, greyifh-brown, earthy fubftance, appearing like an indurated earth, and glittering in fome few places with fmall gloffy particles. This is found in great plenty in fome of the clay-pits about London. *Hill's* Hift. of Foff. p. 613.

PYRIPOLYGONIUM, in natural hiftory, the name of a genus of foffils, the characters of which are, that they are compound metallic bodies, of a regular figure, confifting of twelve planes. See Tab. of Foff. Clafs 5.

There is only one known fpecies of this genus, tho' fubject to great varieties in its appearance; and this has been by authors hitherto confounded, with many other bodies of very different nature and figure, under the general name pyrites.

The *pyripolygonium*, when perfect, is an extremely elegant and beautiful foffil; but this is a ftate it is very rarely found in. It is moderately firm, of a compact texture, and very heavy; tho' its natural figure be a regular body, compofed of twelve planes, yet it is fubject to great imperfections and irregularities. It often feems to want one or more of its fides, and not unfrequently, from the accidental breaking of fome of its angles, to have more than its number; and very often has a great many other fmaller and lefs perfect bodies of its own kind, growing to its larger and lefs perfect fpecimens. It is found from the twentieth part of an inch, to four inches in diameter; but its moft common fize is about a third of an inch. It is naturally of a polifhed and fhining furface, and of a pale whitifh yellow; but fometimes it is brownifh, or of an iron colour.

It is not unfrequent in Cornwall and Devonfhire; but is much more common in Germany. *Hill's* Hift. of Foff. p. 621.

PYRITES, (*Cycl.*) in natural hiftory, a name ufed by Dr. Hill as the claffical term for the lefs regularly figured bodies of the number of thofe ufually called, too indeterminately, by that name. See Tab. of Foff. Clafs 5.

According to this diftinction *pyritæ* are compound, inflammable, metallic bodies, found in detached maffes, but of no determinately angular figure. Of this clafs there are two general orders of bodies; the firft, thofe which are of a plain and fimple internal ftructure; and the fecond, thofe which are regularly ftriated within: and of each of thefe there are two genera. Thofe of the firft are:

1. The *pyriplaces*. Thefe are *pyritæ* of a fimple internal ftructure, and covered with an inveftient coat or cruft.

2. The *gymnopyres*. Thefe are *pyritæ* of a fimple internal ftructure, and naked, or not covered by any inveftient coat or cruft.

The genera of the fecond order, or the ftriated *pyritæ*, are,

1. The *pyritricha*. Thefe are the *pyritæ* of a fimply ftriated ftructure.

And, 2. The *pyritrichiphylla*. Thefe are the *pyritæ* whofe furfaces are covered with foliaceous flakes, made by a continuation and expanfion of the ends of the ftriæ. *Hill's* Hift. of Foff. p. 612.

The feveral fpecies of each of thefe genera, fee under the feveral generical heads, PYRITRICHUM, &c.

Diofcorides mentions only one kind of *pyrites*, which is the common yellow fpecies. Avifenna and the other Arabians mention two yellow forts, a white one, and a ferrugineous one. None of thefe authors made any diftinction between the marcafites and *pyritæ*, but this fort of matter, whether formed into fmall nodules, or continued ftrata, was called indifferently by one or other of thefe names.

The four kinds of this ftone mentioned by the Arabians are called from their colours, the golden, the filver, the braffy, and the ferrugineous *pyrites*. The oldeft authors are of the opinion of Diofcorides, and mention only one kind, deducing them all from the fame principles, and fuppofing their variety of colours to be only owing to accidents. Ariftotle and Theophraftus thus mention the *pyrites* as one thing, under the name *mylia*, which having been tranflated *molaris lapis*, has been underftood by fome to mean fome fort of mill-ftone, or other coarfe ftone fit for fuch purpofes; and by that means the whole fenfe of the authors has been perverted and mifunderftood.

Pliny mentions two kinds of the *pyrites*, the gold and the filver kind: he tells us, there is a ftone, with fome refemblance of brafs in its appearance, which is found in Cyprus, and about Acarnania; and that it is of two kinds, yellow and white. It is clear from this, that this author had con-

sulted some other of the Greeks besides Dioscorides and Theophrastus, from whom he principally furnishes himself with these accounts; but he makes no mention of the rust-coloured or ferrugineous *pyrites*, which is as common as any of the others, even in the country where he wrote: and thence it is evident, that he did not write from his own observation, tho' in some places we are not able to trace him up to his originals, which may be lost. Avisenna tells us, that cadmia was made of the *pyrites*, that is, the cadmia fornacum, or tutty. Pliny and Dioscorides do not in all respects agree as to the several kinds of factitious cadmia; and tho' Pliny does not mention this particular kind of it, Dioscorides tells us of such a sort made in some places by burning the stone called *pyrites*.

The principal contents of *pyritæ* may be in general guessed at from their colour. The white *pyrites* usually contains arsenic, the yellowish contains sulphur and iron, and the fully yellow sulphur and copper. The colours, therefore, make a very essential mark for the distinction of the several kinds of this fossil The yellowish *pyrites*, that is, such as contains iron and sulphur, is found in the strata of several kinds of stone, in clay, and in the earth lying over the mines of several metals. The white, or arsenical *pyrites*, and the fully yellow, are less common, but are usually met with about mines. *Agricola* de Metall.

It is a matter of great difficulty to ascertain the time of the formation of fossils. Many of them seem to have remained in their present state, unaltered, from the beginning of the world; but many have also been formed in later times, and continue to be formed to this day. Of the number of these last the stalactitæ, or stony icicles, hanging down from the roofs of grottos are known to be; and it is equally certain, that the *pyritæ* also are so formed, for many of the stalactitæ in the caves dug by the German miners are found to be coated over in several parts with *pyritæ* [a]; and even in our own kingdom, pieces of wood buried in clay that contains *pyrites*, such as is commonly dug to make tiles, if taken up again after a number of years, is always found impregnated with this substance, forming veins in it, and sometimes nodules on its surface. [[a]Act. Erudit. Ann. 1726. p. 273.]

The *pyritæ* affixed to stalactitæ are finer than the other kinds, and it appears very evident to such as have thoroughly considered the process of nature in them, that they are not formed of particles brought together by water, in the manner of the *pyrites*, in wood buried under clay, or in the manner of these stalactitæ themselves; but are composed of infinitely minute particles, brought together by their mutual attractions on a proper basis, and which had been before floating in the air.

The antients in general supposed, that copper was contained in the *pyrites*; but they had no opinion that iron was a part of it, tho' it is certain that iron is the basis of almost all of them, and copper has a part only in a very few: but this was the effect of judging from appearances, instead of having recourse to experiments. Our own Lister has the honour of being the first author who has treated properly of them, and found out their true and general basis to be iron; but he carries it too far when he supposes them to be all properly iron ores: for this is not the case, many of them, which contain no other metal beside iron, yet holding it in small quantity, and in such a combination of other principles, that it is scarce extricable from them, and some kinds contain no iron at all. *Lister* de Font. Medic. Angliæ.

Berger, who has written on the Caroline baths, has taken up the subject, and improving upon Lister's plan, has given a much more just account of them. He allows that iron seems the basis of great numbers of the *pyritæ*, and that this is evident from the observation, that the remaining matter of many, of them, after burning away the sulphur, is found to be attracted by the magnet; but he observes also, that in many copper is mixed with the iron, and that tho' iron is in general found in even those kinds which give the most obvious proofs of copper, yet there are some in which there can no iron be found.

This author observes also, that besides the metalline particles, whether iron or copper, there is also contained in the *pyritæ* an unmetallic earth, which is in the composition of this stone most equally mixed and perfectly blended with the particles of these metals, and with those of the salts and sulphurs contained also in the mass. Sulphur also he acknowledges to make a great part of many of the *pyritæ*, particularly of all the yellowish and full yellow kinds. The white or silvery *pyrites* contains less sulphur than any of the others, and the yellow or venereal *pyrites*, tho' it contain much arsenic, yet does not fail to contain sulphur also in considerable quantity. *Berger* de Font Carolin.

The mention of gold and silver in the *pyrites* is very common among authors, but the colour of these stones seems principally to have given ground for that opinion In reality these metals are very seldom found naturally making parts of the *pyrites*, and when they are, it is only in a very inconsiderable quantity. But in those specimens found about the mines of gold and silver, the particles of those metals assembled into visible masses are sometimes found imbedded in lumps of the *pyrites*; and such pieces of this stone may then well be said to contain those precious metals. The occasion of this accident, however, is no more than this, that the *pyrites* is formed in mines and other places at this day; which is plain from its being in some places found adhering to the sides of stalactitæ, as has already been mentioned: and in like manner it might adhere to particles of gold and silver, and thereby give ground to the supposition of their being parts of it.

The common *pyritæ* of our clay-pits and sea coasts are used in the making of coperas or vitriol; but among these there is found a very great difference, some of them turning themselves very easily to vitriol, when only exposed to moist air; others doing it with more difficulty; and some not at all, tho' exposed many years. Some also yield all their vitriol at once, on pouring warm water on them; while others must lie exposed to the air at several different times, and roasted in the mean while in order to obtain it. The settled observations on this subject, as collected from experiments, are these:

No *pyrites* which contains any copper, or any arsenic, will of itself turn into vitriol, but requires a previous roasting.

The sulphureous iron *pyrites*, void of copper or arsenic, all turn to vitriol on being only exposed to the air; and that the sooner or later, as they are of a more or less compact substance. The fibrous or radiated *pyritæ* are usually of this kind; but this is no general rule, for there are some radiated ones which remain whole years unaltered in the air.

Copper and arsenic always resist the shooting of the salts of the *pyrites*, or its turning to vitriol; but these are not the only agents that resist this change, for in some merely ferreous and sulphureous *pyritæ* the change is not made but with much time and difficulty. *Henkell*, Pyritol.

It is remarkable also, that vitriol is found in some *pyritæ*, if water be poured upon them immediately after the roasting; while others will not yield any till they have been afterwards exposed to the air. It even seems, that we are to look into the air for the cause of the appearance of vitriol in the coperas stones. This it may greatly assist in effecting, as it carries a quantity of moist vapours in it: for it is well known, that the acid of sulphur has not the power to resolve iron into the form of a salt without the addition of water; nay, oil of vitriol, or of sulphur, being moderately concentrated, tho' it be then diluted with much more water than it is united with while yet in sulphur, does not even dissolve filings of iron unless there be four times or six times as much water poured to it. Water alone, however, tho' a great and necessary agent, cannot be supposed to effect the whole change; for tho' there are some of the *pyritæ* that yield their vitriol by means of it, yet there are others that do not; and some *pyritæ* are presently turned into vitriol, when exposed to the air, which had before remained for many years under water unaltered. Of this kind there are many on the shores of the sea in most parts of Europe. In England particularly we have them in great plenty in Sheppey Island in Kent. These *pyritæ* will long resist the change into vitriol, when in the air, and yet they evidently contain no copper nor arsenic.

There is also a kind very common on the shores, which resembles wood in texture and appearance; and has probably once been wood, but has now its pores filled with the *pyrites*: of these many lie buried a foot or more deep in the sand under the sea water; and in that state they never shoot into vitriol, but are of a firm texture and considerable hardness, and when broken look very bright within, and have no taste of vitriol, nor give any mark that they contain any: yet these, if they are taken up and exposed to the air for a fortnight, lose all their brightness and their hardness, and mouldering to pieces, become so rich in vitriol, that it forms itself into regular crystals on their surfaces. Now if moisture alone was sufficient to produce this effect, there is no reason why they should not have been resolved into vitriol under a very moist sand. The great cause we are able to assign, appears to be the vague acid, so common in the fossile world, and filling also the region of air; but an ingenious reasoner will still own, that tho' this may do much, yet there must be some other cause, yet undiscovered, for the production of vitriol in these fossils; since this, as well as the moisture of the air, ought to act more equally than we find by experience it does on these stones, if all were owing to it. *Henkell*, Pyritol.

In the exposing these copperas stones to the air, if it be a moist season, no farther care need be taken of them than the piling them up in a heap; but moistening them now and then is a necessary circumstance in dry seasons, and in this case the water should be sprinkled on them in small quantities at a time, and the heaps now and then turned and new made. Much depends on this management, the same quantity of stones yielding twice as much copperas, with proper care, as they would without it

When the matter of the *pyrites* is mixed with the lead ores, the method of separating the metal by assaying is this: roast two centners of the ore, as in the usual method, and keep a stronger fire than when the ore is pure. The *pyrites*, especially when it is merely iron, hinders an ore from easily growing clammy, or turning into large lumps, or entirely melting. When the ore is sufficiently washed, let it cool, beat it to powder, and repeat the roasting to a third fire, till when it is red hot in the fire, there is no smell of sulphur: then mix the

ore

ore with six centners of the black flux, and two of sandiver, and finish the work in the common way, only making the fire greater, and continuing it longer, toward the end of the operation. *Cramer*'s Art of assaying, p. 292. See the article Lead-*ore*.

PYRITICUM *liquamen*. See Liquamen *pyriticum*.

PYRITRICHIPHYLLUM, in natural history, the name of a genus of fossils of the class of the pyritæ, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose masses not of any regularly angular figure, and of a striated texture, with foliaceous ends to the striæ, appearing on the surface or within the mass. See Tab. of Foss. Class 5.

Of this genus there are only two known species; one having the foliaceous ends of the striæ on the outer surface of the mass, and the other having a smooth external surface, and the foliaceous ends of the striæ covering the sides of internal hollows. *Hill*'s Hist. of Foss. p 617.

The first is a fossil of great beauty, of a very firm texture, remarkably heavy, and usually found in large masses of an orbicular or oblong figure: these masses are sometimes composed wholly of the matter of the pyrites, and in others they are only coats of that substance surrounding stones.

It is of a very closely striated texture, and the striæ are broad, but unequally so, and their extremities at the surface of the mass are beautifully formed into several series of thin foliaceous plates, which usually cover all the superficies, and stand up to several heights and in different angles, but mostly leaning one way; they are of unequal thicknesses, being composed of different numbers of plates, and are usually notched at the ends. The whole is of a somewhat deep green, with a cast of olive or amber colour, and when it is fresh broken, is very bright and glittering.

The second is a fossil of equal beauty with the former, tho' of a very different appearance; it is very hard and very heavy, and is always found in detached masses; but those of a very singular kind, for they are always more or less hollow. These masses are of various figures and appearances, sometimes round and like pebbles, but more frequently full of odd protuberances, like the flints in our chalk pits; and sometimes the masses of it are found running over the surfaces of stones in form of crusts, which are variously protuberant in different parts, and rise into frequent beautiful tho' irregular tubercles.

The outer surface of this species is usually very bright and glossy, and perfectly smooth, as if wrought by art, even on the tubercles themselves. It is usually a sort of crust even in its most solid masses, seldom being above half an inch thick, and of a very beautifully striated texture, the striæ being remarkably fine and slender. These, tho' they unite so at their superficies as to form a very smooth surface, yet at their other ends, where they terminate at the hollows of the masses, are expanded into very elegant series of foliaceous plates, usually approaching to a square figure, and not standing erect, as in the other species, but lying horizontally and almost perfectly flat over one another: these are composed of flakes not thicker than those of many of the foliacious talcs. The whole is usually of a gold yellow, and very bright and beautiful; but the outer surface often contracts a dull brownish hue on being long exposed to the air.

The first of these is found in many of the English and German mines, the other has been yet only found in the mines on Mendip hills in Somersetshire, but there in considerable plenty. *Hill*'s Hist. of Foss p. 618

PYRITRICHUM, in natural history, the name of a genus of pyritæ, the characters of which are these: they are compound, inflammable, metallic fossils, always found in detached masses of no regularly angular figure, and of a simply striated internal structure. See Tab. of Foss. Class 5.

Of this genus of pyritæ there are three known species, 1. A globose one, with an irregular surface. 2. A globose one covered with angular tubercles. 3. A silver-coloured globose one, with a smooth surface.

The first is considerably hard, and very remarkably heavy, and is usually of a roundish form, tho' sometimes oblong; sometimes it is full of irregular prominences on the surface, and sometimes is a complex mass, consisting of a great number of roundish masses of smoother or rougher surfaces joined together. It is very various in size; the more common specimens of it are of six or eight ounces weight, tho' there are others of less than an ounce, and some of several pounds. The prominences on the surface are usually broad and depressed, and these are frequently marked with irregular short lines, and raised in ridges. When broken, it is found to be of a very regular striated structure; the striæ are not very broad, and usually run from the center to the circumference. It is of a pale whitish green within, and is covered with a brown or ferrugineous crust.

The second is a very firm and hard body, usually of an orbicular figure, and sometimes, tho' rarely, oblong; it is of a very remarkably rough surface, being covered with pyramidal tubercles, with very obtuse ends. These are of a quadrangular figure, and have very broad bases: they sometimes incline, or bend a little; but more usually they stand perfectly upright, and are placed so close together, that they croud and injure one another's figure at their bases. The whole is of a ferrugineous or rust colour without, and of a yellowish colour within, beautifully striated, and very bright and glittering.

The third is an extremely elegant and beautiful species, it is but moderately hard, tho' remarkably heavy, and is usually of a regularly orbicular form, tho' sometimes it varies from it like the other pyritæ. Its most frequent size is about an inch and half in diameter; but it is sometimes found as small as a nut, or a schoolboy's marble, and sometimes of more than two pounds weight. Its surface is usually smooth and even, and it is never covered with any coat or crust. It is of a very regularly striated internal structure, and of a beautiful silvery green colour: the striæ are moderately broad and run very evenly from the center to the circumference; and very often there is a small and firm central nucleus, which is much harder than the rest of the mass, and is of a plain not striated structure.

All the three species are found plentifully in different parts of the kingdom: the first in all sorts of strata, and often loose on the ground; the second, principally in the chalk pits of Kent and Sussex; and the last in Essex and Hampshire, and very frequently in the German mines. *Hill*'s Hist. of Foss p. 617.

PYRMONT-*waters*. The country all about where these springs are, abound with materials which give virtue to the waters; and the quarries of stone, wherever they are dug, send up spirituous and martial exhalations as well as the springs that run from them, and the water among them has in general a vitriolic taste. Iron is found all about the place also, under the appearance of a yellowish earth or ochre, which contains so much of that metal, that it may be worked as an ore of it to great advantage. Ferrugineous stones are also found in great abundance in the neighbourhood of the place; these may be also worked as iron ores, and the selenites is found in the strata of earth that make up the hills thereabout, in great abundance, and in beautiful perfection.

The waters themselves, tho' they shew evident marks of an alkali, yet have also an acid principle in them, of the nature of the common acid of sulphur, except in this, that in these waters the acid carries with it a subtle mineral oil or fattiness; and mixing with the common alkali salt, which is found in all mineral waters, these together form a neutral salt: but as in the composition of this salt there is much more alkali than acid, it is necessary that the water should shew alkaline rather than acid qualities. The analysis shews also, that the waters contain a stony matter embodied in them, which is pure, insipid, colourless and tasteless, and seems to be in nothing different from common crystal. The earth about the springs contains also a great number of lumps of a clayey matter, of the size of a walnut, and of a yellowish colour; in all of which, when broken, there is found pure crystal in small shoots, sometimes in its own regular figure, and sometimes irregular and mutilated.

A water containing these principles thus combined, cannot but possess those virtues we find so eminent in this; these are, the opening obstructions, correcting the sharpness of the humors, and restoring the solids to their due state. *Seipp*, Nova Descrip. Font. Pyrm.

The history of these waters is accurately given by Hoffman in his observations on them, both in their natural state and in mixture with other bodies.

He first observes, that they contain a volatile and subtle principle, greatly more penetrating and strong, as well as in larger quantity, than any other mineral water; but that this is not to be expected in them any where but upon the spot, for those who transport them to other places are constrained to let a part of this fly off to preserve the rest. If either glass or earthen vessels be filled at the spring, and immediately corked and fastened down, the consequence is, that they will burst on the first motion or heat of the weather. They are, therefore, forced to fill them only in part at first, and let them stand a while for this subtle spirit to exhale, and then a while after the filling them up, to cork and fit them for carriage.

2. If they are drank upon the spot in a morning on an empty stomach, they affect the nose with a pungent tingling, and disturb the head for many hours afterwards.

3. If they are taken at the spring, they purge but very little; but if taken in another place, after transportation, they purge considerably more, and render the stools black. It is observable also, that if they are left in an open vessel a few days, their virtue wholly exhales, and they no longer purge nor render the stools black.

4. If tea-leaves, balaustine-flowers, or galls, are put into this water, they first change it to a blue, from that to a purple, and finally to a black. This is a ready proof, that black is only a deep purple, and purple only a deep blue: a little spirit of vitriol added to this liquor destroys all the colour, and renders it limpid as before.

5. If any acid be mixed with *Pyrmont water*, there is raised an effervescence, and bubbles of air are carried up in great quantity; and this whether the stronger acids, such as spirit of vitriol, or aqua fortis, be used; or the weaker, as vinegar, lemon-juice, or Rhenish wine.

6. If an alkaline liquor be added, whether it be volatile, as the spirit of sal armoniac; or fixed, as the oil of tartar, there is

is no ebullition raised, but the liquor becomes turbid and milky. If spirit of vitriol be afterwards added to this, to saturate the additional alkali, the liquor becomes limpid again.

7. Cow's milk mixed in equal quantity with *Pyrmont water* does not coagulate, but, on the contrary, becomes thinner than before, and is preserved from turning sower so soon as it otherwise would in hot weather. This is a proof that there is no predominating acid in these waters.

8. If syrup of violets be added to *Pyrmont water*, it turns it to a beautiful green. This is a proof of the alkaline nature of these waters; and it is farther proved by adding spirit of vitriol, or any other acid, to this green liquor, which on that becomes limpid again.

9. Four pints of this water evaporated over a gentle fire, yield no more than two scruples of a dry residuum. Oil of vitriol being poured on this, acid effervescence arises, and with it an acrid and pungent vapour, like that produced by mixing oil of vitriol and common salt. If spirit of vitriol be used instead of the oil, the effervescence is in a less degree, and the salt is in part changed to a bitter saline mass, the remainder separated from which proves to be a calcarious earth no longer fermenting with the spirit of vitriol.

10. If a quantity of *Pyrmont water* be exposed twenty four hours to the open air in a bason, it will at the end be found to have lost all its virtues, tasting wholly insipid, and being turbid instead of the fine clearness it had before, and a yellow ochreous earth is precipitated to the bottom; after this the liquor will no longer shew any of those qualities which were before its distinguishing characters, it will no longer ferment with acids, nor turn black with galls, nor green with syrup of violets.

It appears from the whole, that the *Pyrmont waters* possess a pure, extremely penetrating, and elastic mineral spirit, and that in a very large proportion; and to this their virtues are principally to be attributed. This mineral spirit, while it remains engaged in a calcareous earth, imitates the properties of an alkaline substance; and when joined with a subtile martial earth, it emulates the properties of vitriol, giving the stools a black colour, and turning a tincture of galls into ink: and while this remains in the water in these forms of an alkaline or vitriolic principle of so great subtilty, it cannot but give them very great virtues in strengthening the tone of the viscera, opening obstructions, and stimulating in a proper manner the excretory ducts, so as to make them duly perform their office; but as soon as by the standing of the water open, or by any other accident, this subtle element is evaporated, all the virtues of the water must be gone with it.

The great quantity of this powerful spirit contained in the waters makes them more fit for the robust and strong constitutions, when depraved by illness, than for the weak and tender ones; but even the tenderest people may take them, only observing to take but a small dose, or to dilute them with an equal quantity of common water immediately before the taking them.

Hoffman also recommends the *Pyrmont water* mixed with equal quantities of milk, on his own experience, in scorbutic and gouty cases. *Hoffm.* Opera, T. 5. p. 143, seq.

Near the famous well at *Pyrmont*, is a stone-quarry under ground, from some parts of which a sulphureous steam comes out, which commonly rises to a small height. Animals held in this steam are soon suffocated, but recover if quickly taken out. When a man stands in this steam, but with his head over it, it proves an excellent sudorific. Dr. Seip proposes to perform cures in several diseases with it. See Phil. Transf. N°. 448. sect. 4. and Misc. Berolin. Tom. V. part. 2. sect 4.

Imitation of PYRMONT *water.* This medicinal water may be imitated very nicely by art in the following manner: take a quart of the purest and lightest water, add to it thirty drops of a strong solution of iron made in spirit of salt, a drachm of oil of tartar per deliquium, and thirty drops of spirit of vitriol, or a little more or less, as is found necessary, not to let the alkali of the oil of tartar prevail too strongly, tho' it must prevail a little. Shake all briskly together, and on tasting it will be found extremely to resemble the true *Pyrmont water*.

The basis on which this is founded is the analysis and trial of the true *Pyrmont water*, by which it is found to contain a subtle aqueous fluid, a volatile iron, and a predominant alkali, all joined together into one brisk pungent spirituous water. The artificial *Pyrmont* thus made, if the proportions are carefully minded, will extremely resemble the natural, and will have the same effects as a medicine. *Shaw's* Lectures, p. 90.

PYROBOLUS, in natural history, a name given by many authors to the stone more generally called *pyrites*; others have called it *siderites*, *pyrobalanus*, *pyropus*, and *othonna*, and the Greeks *mylias*. Among the translators and interpreters of the works of authors who have treated on these subjects, there has been great confusion concerning this stone, few of them understanding any thing of the subject, and rendering its descriptions so injudiciously, that they may rather be thought to belong to other stones. See PYRITES.

PYROCTOGONIUM, in natural history, the name given by Dr. Hill to a genus of fossils usually comprehended by authors, with many other bodies of a different figure and structure, under the general name pyrites.

The characters of the *pyroctogonium* are these: it is a compound, inflammable, metallic body, of a regular octohaedral figure, or composed of eight planes.

There is only one known species of this genus, which is a very singular and elegant fossil, being composed of eight triangular planes; these being the sides of two quadrilateral pyramids, with broad bases, which being joined base to base, constitute the *pyroctogonium*. See Tab. of Foss. Class 5.

This figure is very regular and determinate in the perfect specimens of this body, but there is scarce any fossil which is more subject to imperfections and accidental variations. Its most perfect state is when the two pyramids of which it is composed are placed evenly one over against the other; but this is but rarely the case, they are often placed unevenly, or slanting; their planes are frequently of very irregular lengths and breadths, and not unfrequently the specimens are found mutilated and imperfect, and very often a number of them cohering in a cluster one with another, and very much mutilating or injuring one another's figure. They are found of all the sizes between that of a pin's head, and an inch in diameter; but the large ones are scarce, and the most usual standard is a third of an inch. They are naturally of a smooth and polished surface, and of the colour of wrought iron; when broken they are bright and sparkling, and of a paler colour than without. When nicely examined as to their internal structure, they are found to be composed like the marcasites, of a number of irregularly arranged foliaceous flakes or plates.

It is found very frequently in Cornwall, Devonshire, and most other of our counties where there are mines. It is sometimes met with loose in the earth, sometimes lodged in the bodies of marcasites, or in the solid fossils, and varies sometimes from its iron colour to a dusky yellow. It is sometimes also found with many specimens connected into a mass; these are seldom uniform in size, and cohere in various directions, often greatly injuring one another's figure. Sometimes also, as in the case of the crystals, they form a large mass, of which the outer surface only is concreted into or covered with regular figures, the whole inner part being a confused substance.

Masses of this kind are not unfrequently found of a regularly orbicular figure, and beset all over with regularly figured *pyroctogonia* of various sizes. *Hill's* Hist. of Foss. p. 620.

PYROLA, *winter-green*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, consisting of several petals arranged in a circular form. The pistil arises from the flower-cup, and ends in a sort of proboscis: this afterwards becomes an umbilicated and striated, roundish, quinque capsular fruit, usually containing a number of very small seeds.

The species of *pyrolæ*, enumerated by Mr. Tournefort, are these: 1. The larger round-leaved *pyrola*. 2. The smaller round-leaved *pyrola*. 3. The *pyrola* with sharp-pointed and serrated leaves. And 4. The shrubby *pyrola*, with flowers resembling those of the arbutus. *Tourn.* Inst. p. 256.

PYROLAMPIS, the *glow-worm*, a small insect remarkable for its shining in the night.

The male and female differ greatly in this species of insect. The male has wings, and is a small fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and somewhat flatted; the wings are shorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light issuing from it, and is not commonly supposed to be at all of kin to the *glow-worm*. See Tab. of microscopical Objects, Class 1. voc. *Cicindela volens*.

The female is what we expresly call by this name. This is a very slow-paced animal, without wings, and somewhat resembling a caterpillar; the head is small, flat, hard, and black, and sharp towards the mouth; it has short antennæ, and six moderately long legs; the body is flat, and is composed of twelve rings, whereas the body of the male consists only of five; it is of a dusky colour, with a streak of white down the back. It is often seen in the day-time, but is not known till in the dark; at which time it is easily distinguished by the glowing light, or lambent flame, that is seen near the tail, issuing from the under part of the body.

PYROMACHUS, a name given by some to antimony when reduced to a stony hardness; and by others to copper, when fused with sulphur, and thus rendered less ductile.

PYRONOMIA, a term used by the chemical writers to express the art of regulating fire, so as to make it subservient to all their processes in a determinate degree.

PYROPHAGI, *fire-eaters*, a name given by some to those juglers and mountebanks who deceive people into a belief that they swallow fire.

PYROPHORUS, the name usually given to that substance called by some the *black phosphorus*. See PHOSPHORUS.

It is made in this manner: take four or five parts of alum, and one part of wheat-flour, calcine this together to a brown or blackish mass; powder this and put it into a vial, stop it loosly with a paper, and set it in a sand heat, so as to make it continue glowing hot for some time; after this, remove the whole

whole from the fire, fuffer it to cool gradually, and finally ftop the bottle very clofe down.

A little of this powder being poured out of the bottle, and expofed to the open air, immediately takes fire, and appears like a glowing coal; but the powder muft be frefh made to have a good effect, for the fun's rays, or the moifture of the air being admitted to it, gradually take away its virtue.

Almoft any animal or vegetable fubftance may be fubftituted inftead of wheat-flour in this procefs, and it will fucceed equally well; but no other falt will do in the place of alum. *Shaw's* Lectures, p. 406.

PYROPHYLACIA, a term ufed by Kircher and fome others to exprefs thofe magazines of fire which are placed in the cavities of mountains and other hollows of the earth, and ferve to fupply the feveral volcanos in the different parts of the world. See VOLCANO.

PYROSCOPIA, among the Greeks, a kind of divination, being the fame with pyromancy and ignifpicium. See the article PYROMANCY, *Cycl.*

PYROSIS, a word ufed to exprefs an intenfe heat and rednefs in the face, fuch as that of perfons who travel in extremely hot weather, and the like.

PYRRHALA, in zoology, the name of a bird well known in England by the name of the *bulfinch*, and called by fome authors *rubicilla*.

It is a beautiful bird, and fings very fweetly; but does great mifchief in gardens and orchards, deftroying the buds of the fruit-trees.

PYRRHOCORNIX, in zoology, a name given by authors to a bird of the crow-kind, defcribed by fome authors as a diftinct fpecies; but Mr. Ray, and other very judicious naturalifts, efteem it the fame with the coracias, or Cornifh chough, or only differing in age or by other accidents. *Ray's* Ornithol. p. 86. See CORACIAS.

PYRROPŒCILOS, in the natural hiftory of the antients, the name by which they call the granite of Arabia, commonly known to this day under the name of the *oriental granite.*

The name is derived from the Greek πῦρ, fire, or fire-coloured, and ποικιλος, fpotted; and the antients having ufed the epithet fiery to yellow, as well as red, fome have imagined the granite muft be a yellow ftone; but it is evident that red is the colour meant by it here. *Hill's* Hift. of Foff. p. 500.

PYRSEPHORUS, πυρσηφορος, in the Athenian feftival, hephæftia, the fame with lampadephorus. See LAMPADEPHORUS.

PYRUS, the *pear-tree*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the rofaceous kind, and is compofed of feveral petals arranged in a circular form. The cup finally becomes a flefhy fruit, ufually of a turbinated fhape, umbilicated, and divided within into cells which contain oblong feeds. *Tourn.* Inft. p. 629.

The fpecies of *pear*, enumerated by Mr. Tournefort, are thefe: 1. The double-flowered *pear*. 2. The fmall, branched, very fweet-fcented fummer-*pear*. 3. The fummer-*pear*, with very fmall and fweet-fcented fruit. 4. The fweet-flavoured fummer-*pear*, partly of a deep red, and partly of a yellow colour. 5. The fmall, yellowifh, fweet-flavoured *pear*. 6. The round, feffile, fweet-flavoured fummer-*pear*, variegated with black fpots. 7. The round, feffile, fweet flavoured, fugar-tafted fummer-*pear*, of a purplifh green colour. 8. The oblong, iron-coloured, fweet-flavoured fummer-*pear*, with tender pulp. 9. The fmall fummer-*pear*, of a whitifh green colour. 10. The greater whitifh fummer-*pear*. 11. The whitifh, fugar-tafted, very fweet-flavoured, fummer-*pear*. 12. The whitifh fummer-*pear*, with a long pedicle. 13. The oval fummer-*pear*, variegated with iron-coloured fpots. 14. The oblong, reddifh, fugar-tafted, fummer-*pear*. 15. The fmall, roundifh, vinous, fummer-*pear*, of a reddifh yellow colour. 16. The fugar-tafted turbinated fummer-*pear*, with tender pulp. 17. The oblong, fmall, afh-coloured fweet-flavoured fummer-*pear*. 18. The globofe, feffile, fugar-tafted, fummer-*pear*, of a whitifh yellow colour. 19. The fugar-tafted, globofe, whitifh fummer-*pear*. 20. The globofe, feffile, fweet-flavoured fummer-*pear*. 21. The turbinated, feffile, red-coloured, and punctated fummer-*pear*. 22. The turbinated, feffile, fweet-flavoured, fummer-*pear*, partly yellow, and partly variegated with red fpots and veins. 23. The long, red, fummer-*pear*, of a fomewhat acid tafte. 24. The globofe, greenifh purple, fummer-*pear*. 25. The globofe, fugar-tafted, fweet-flavoured, fummer-*pear*, of a yellowifh colour, blended with red and white. 26. The great oblong fummer-*pear*, partly red and partly white. 27. The long fummer-*pear*, of an extremely bitter tafte. 28. The autumnal-*pear*, with very fweet fruit, which diffolves in the mouth. 29. The feffile, fugar-tafted, fweet-flavoured, autumnal-*pear*, of a greenifh yellow colour, and diffolving in the mouth. 30. The turbinated autumnal-*pear*, of a green colour, variegated with blood-coloured veins. 31. The roundifh autumnal-*pear*, of a reddifh iron colour, fometimes fpotted. 32. The long, green, fweet-flavoured autumnal-*pear*, which diffolves in the mouth. 33. The tuberous, feffile, autumnal-*pear*, of a greenifh yellow colour, variegated with black fpots, with fugar-tafted tender pulp. 34. The tuberous, feffile, fugar-tafted, autumnal-*pear*, with hard pulp. 35. The globofe, iron-coloured, very fweet-tafted autumnal-*pear*, with tender pulp. 36. The turbinated, feffile, autumnal-*pear*, with yellowifh fruit, diffolving in the mouth. 37. The globofe, iron-coloured, autumnal-*pear*, with vifcid pulp. 38. The Englifh *pear*, with long fruit, variegated with iron-coloured fpots. 39. The very fweet-flavoured, fugar-tafted, pale-red, oblong, autumnal-*pear*. 40. The great afh-coloured, oblong, autumnal-*pear*. 41. The roundifh, fweet-flavoured, red, autumnal-*pear*. 42. The fmall, globofe, punctated, autumnal-*pear*, of a greenifh red colour. 43. The fmall, tuberous, feffile, darkifh-coloured, autumnal-*pear*. 44. The tuberous, turbinated, punctated, autumnal-*pear*, of a yellowifh or whitifh colour. 45. The turbinated, yellow, or ftriated, fubacid, autumnal *pear*. 46. The turbinated, fading yellow, and fomewhat bitter, aromatic tafted, autumnal-*pear*. 47. The turbinated, feffile, yellow, autumnal-*pear*, with a fomewhat bitter aromatic tafte. 48. The turbinated, feffile, yellow, autumnal-*pear*, with ftriated ribs. 49. The tuberous, angular, autumnal-*pear*, of a yellowifh, fading green colour. 50. The tuberous autumnal-*pear*, with a thin, pellucid fkin, partly red, and partly yellow. 51. The oval, fomewhat angular, autumnal-*pear*, with a very tender fkin of a faint yellow. 52. The large winter *pear*, of a reddifh yellow colour, and fhaped like a pyramid. 53. The pyramid like winter-*pear*, partly purple, variegated with black fpots, and partly yellow. 54. The great oblong, turbinated, iron-coloured, Windfor-*pear*, umbilicated on both fides. 55. The great quince like winter-*pear*, partly yellow, and partly purple. 56. The very fweet-flavoured, yellow, winter-*pear*, with a thick pedicle. 57. The great feffile, winter-*pear*, of a yellowifh grey colour. 58. The globofe, feffile, winter-*pear*, of an afh-colour, variegated with large dark fpots. 59. The long yellow winter-*pear*. 60. The fmall winter-*pear*, of a yellow colour, variegated with red fpots, and a bitter tafte. 61. The oval, fugar-tafted, winter-*pear*, of an iron colour, with a faint admixture of purple. 62. The citron-fhaped, hard, and very fweet-flavoured, winter-*pear*. 63. The globofe, feffile, fugar-tafted, fweet-flavoured, winter-*pear*. 64. The turbinated and unequally tumid winter-*pear*, partly purple, and partly yellow. 65. The great globofe winter-*pear*, of a yellow colour, variegated with red fpots. 66. The turbinated, feffile, winter-*pear*, of a fubacid tafte, a yellow colour, and covered with a multitude of fharp points. 67. The turbinated, feffile, yellow, fugar-tafted, winter-*pear*, of a fweet fmell, and diffolving in the mouth. 68. The tuberous, turbinated, greater fugar-tafted, winter-*pear*, diffolving in the mouth. 69. The oblong, fugar-tafted, fweet-flavoured, winter-*pear*, of a partly deep and partly faint iron colour. 70. The oblong, winter-*pear*, of a very pale red colour. 71. The oblong, yellowifh green, winter-*pear*, of an aufterely fweetifh tafte. 72. The oblong, tuberous, fubacid, winter-*pear*, of a punctated yellow colour. 73. The tuberous, fugar-tafted, punctated, yellowifh green, winter-*pear*. 74. The long, whitifh green, winter-*pear*, diffolving in the mouth. 75. The long, yellowifh green, winter-*pear*, diffolving in the mouth. 76. The feffile, yellowifh green, winter-*pear*, fpotted, umbilicated on both fides, and diffolving in the mouth. 77. The globofe, pale green, tuberous, punctated, winter-*pear*, diffolving in the mouth. 78. The great pyramidal, whitifh, fugar-tafted, fweet-fcented, winter-*pear*, diffolving in the mouth. 79. The feffile, iron-coloured, very fweet-fcented, winter-*pear*, diffolving in the mouth. 80. The globofe, citron-fhaped, punctated, yellow, winter-*pear*, diffolving in the mouth, and very fweet-fcented. 81. The long, fugar-tafted, yellowifh green, winter-*pear*, diffolving in the mouth. 82. The feffile, winter-*pear*, partly purple, and partly yellow. 83. The great, double-headed, winter-*pear*. 84. The tuberous and angular winter-*pear*. 85. The oval, paler green, winter-*pear*, with a very long pedicle, and befet with tubercles. 86. The wild *pear*. 87. The great wild *pear*. *Tourn.* Inft. Bot. p. 628, feq. See the article PEAR.

PYULCUM, a word ufed by the antients to exprefs an inftrument ufed in their times to draw out the pus from the bottom of deep finufes, probably a fort of canula.

Q.

QUACHILTO, in zoology, the name of a very beautiful Brafilian bird, of the moorhen kind, called alfo *yacacintli*, and *porphyrio Americanus*.

It is of a fine blackifh purple colour, variegated with white. Its beak is white, while young; but becomes red as it grows older, and has a naked fpace at its bafis, refembling, in fome fort, the coot. Its legs are of a yellowifh green. It lives about the waters, and feeds on fifh; yet is a very well tafted fifh. It imitates the crowing of a common cock, and makes its mufic early in the morning. *Marggrave*'s Hift. Brafil.

QUADRANGULARIS *pifcis*, the *fquare-fifh*, in zoology, the name of a fifh, which in its moft ufual fize, is about fifteen inches long, four inches high in the middle, and three inches and an half over. The forehead is fquare, a little hollow, and, by the eminency of the eyebrows, two inches and an half over. The nofe blunt, and not very fteep, with two holes in the place of noftrils, and the mouth very fmall. The back is a little convex toward the tail, and on the fides a little obtufely angled; as is alfo the belly, which is plain and flat, and a little rifing toward the tail. It has five fins, two near the gills, two near the tail, and the tail-fin, which is confiderably long. Part of the head and tail are covered with a foft fkin, the reft of the body with a kind of cruft, adorned all over with little round knots, reduced for the moft part into hexagonal figures, and fubdivided into equilateral triangles. *Grew.* Muf. Reg. Soc. p. 110.

QUADRANS, (*Cycl.*) a word ufed by fome authors to exprefs a fourth part of a pound, that is, three ounces Troy weight, or four of the averdupois.

QUADRATING *of a piece*, in gunnery, is examining whether the piece be duly placed in its carriage, and that the wheels be of an equal height.

QUADRATO, or QUADRO, in the Italian mufic, is a name given to the note B, when it comes in the natural or diatonic order, and is thus marked ♮. It is a femitone minor higher than the B mol, or ♭, and in refpect of that may be called *fharp*. See FLAT and SHARP, *Cycl.* and *Suppl.*

QUADRATULUS, in ichthyology, a name given by Rondeletius to the fifh called by other authors the *plateffa*, and *paffer lævis*, in Englifh the *plaife*.

This is properly a fpecies of the pleuronectes, and is diftinguifhed from the reft of that genus by Artedi, by a name expreffing that it has the eyes and fix tubercles on the right fide of the head, and fmooth fides, and a fpine at the anus. See the article PLEURONECTES.

QUADRATURE *of the hyperbola*. See HYPERBOLA.

QUADRATUS (*Cycl.*)—QUADRATUS, in zoology, a name by which fome authors have called the flat fifh, called *paffer* by moft writers, and in Englifh the *plaife*. *Rondelet.* de Pifc. p. 331.

QUADRATUS, in anatomy, a fmall, flat, flefhy mufcle, of the figure of an oblong fquare, fituated tranfverfely between the tuberofity of the ifchium and the great trochanter. It is fixed by one extremity along that obtufe line which runs from under the acetabulum, toward the lower part of the tuberofity of the ifchium; from whence it runs directly towards the great trochanter, and is inferted in almoft all the lower half of the oblong eminence in that apophyfis, but chiefly in the fmall rifing or tuberofity in the middle of that eminence. *Winflow*'s Anat. p. 211.

QUADRATUS *lumborum, five lumbaris externus*, a fmall, oblong, flat mufcle, irregularly fquare, narrower at its upper than at its lower part, lying along the fides of the vertebræ lumborum, between the laft falfe rib and the os ilium. It is fixed below to the external labium of almoft all the pofterior half of the crifta of the os ilium, to the ligamentum facro-iliacum, and a little to the os facrum, by a flefhy plane, the fibres whereof run obliquely backward; from thence it runs up between the facro-lumbaris and pfoas, by both which it is partly hid, and is inferted in the extremities of all the tranfverfe apophyfes of the loins by oblique tendinous digitations. It is alfo fixed by a broad infertion in the twelfth rib, on the infide of the ligament which lies between it and the longiffimus dorfi, by which that rib is connected to the firft vertebra of the loins. *Winflow*'s Anat. p. 249.

QUADRATUS *mufculus*, in anatomy, is alfo a name given by Winflow to the mufcle of the lips called by Albinus and Cowper *depreffor labii inferioris*.

QUADRIGÆ, among the Romans, chariots drawn by four horfes, which were harneffed all a-breaft, and not two and two. *Pitifc.* in voc.

QUADRISETÆ, the *four-haired fly*, a term ufed by the writers in natural hiftory to exprefs thofe flies of the feticaudæ or hair-tailed kind, which have four hairs or briftles growing from the tail, as the others have three, two, or one.

QUADRULA, in natural hiftory, a word fometimes ufed in the fame fenfe as teffela, and fpoken of the cubic pyrites. Sometimes it is ufed alfo as the name of thofe little fpangles of fhining matter that are mixed among fand. Thefe are generally fragments of talc, and are of various colours, white, yellow, and blackifh.

Solinus has ufed the word *quadrula* to exprefs the fragments of yellow talc that are found in that fand called *ammochryfos*, or golden fand. He miftakes thefe fhining particles for maffes of real gold, and makes the fand itfelf a kind of precious fubftance ranked among the gems, and brought from Perfia; but in this he does not agree with the reft of the antients.

QUADRUPEDS, (*Cycl.*) in natural hiftory. The effential character of *quadrupeds* is, that they have a hairy body and four feet, and that the females are viviparous, and give fuck to their young. *Linnæi* Syftem. Natur. p. 33.

Alated QUADRUPEDS. Among the many fabulous things with which natural hiftory has been loaded, ftories of flying *quadrupeds* feem to claim a very high rank; the gryphon, the *quadruped* dragon, and a great many other imaginary animals, having been introduced fo ferioufly among the defcriptions of real animals, that too many have been taught to believe them. Scheuchzer, in his *Phyfica facra Jobi*, has done much toward difcountenancing fuch relations, and Hyacinthus Gemma, who has written exprefly de fabulofis animalibus, has added much on the fame occafion: yet all is not done. The world have late hiftories of lemmas and bafilifks, which never exifted but in the imagination of the relator, or in the fubtle contrivances of the fabricator; as is evidently the cafe in the bafilifks, which we find in the mufæums of the curious, and which are all made out of the wray-fifh. And the generality of readers are fo fond of any thing that is marvellous, that thefe things are fure to be remembered, while perhaps all the truths in the book are forgotten.

Tho' moft of the ftories of *alated* or flying *quadrupeds* are falfe, yet there are evidently fome animals which fhew, that this property is not denied to all *quadrupeds*. We have bats in every part of this kingdom, and the Eaft and Weft Indies are not without them; and whoever accurately examines this creature, will find that it has nothing of a bird but that one property of flying; and that what are called its wings, and ferve it in the office of wings, are in reality only its fore-feet extended, and webbed with a peculiar kind of membrane.

There is a fpecies of flying lizard very common in Java, and called by many the *flying dragon*. Bellonius had led the world into a great error in regard to this animal, having miftaken it for a two-legged creature, and defcribed and figured it as fuch; but Bontius, and others fince his time, have fet us right about it from their own obfervation, and Pifo, as well as many others, have defcribed it truly as a *quadruped*.

Thefe creatures are properly enough called flying animals, as they can fufpend themfelves a long time in the air, and move about in it at pleafure; but lefs accurate writers have added to the numbers of flying *quadrupeds* the common fquirrel, and feveral other creatures which live in woods, and being very light in their bodies, and very ftrong in their legs, can leap or throw themfelves forward to a great diftance, and by this means pafs from one tree to another. Of this kind the moft eminent is that fpecies called the *flying fquirrel*, which has a fort of membrane which it expands on each fide to catch the air, and fupport it from falling in its leaps; which by this means it makes very long, and feems to fly, efpecially when it throws itfelf from the top of a very high tree to a low fhrub.

Upon the whole, the ftandard of the flying or *alated quadrupeds* feems to be properly enough reducible to this: that the words flying and *alated* are not fynonymous terms, and that there are three kinds of flying among the *quadruped* clafs. The firft abfolute and fwift, flying as perfect as in birds; this peculiarly belongs to the bat, which is the only *alated* or winged *quadruped*, properly fpeaking. 2. An imperfect flying by means of certain membranes ferving as wings, but imperfectly, and not turning quick, or enduring long flights; fuch is the flying of the lizard, which is not properly an *alated* animal. And laftly, the imperfect flying of the fquirrel kind, which even in that fpecies called, by way of eminence, the *flying fquirrel*, is not properly flying, but only long leaping; the creature being able to turn but very little out of a right line, and only to fufpend itfelf during a fhort time in a leap from a high place to a lower. Phil. Tranf. N°. 427. p. 34.

QUADRUPLATORES, among the Romans, were informers, who had the fourth part of the confifcated goods for their pains. *Pitifc.* in voc.

QUÆRENS *non invenit plegium*, a return made by the fheriff upon a writ directed to him with this claufe, viz. *Si A. fecerit B. fecurum de clamore fuo profequendo*, &c. F. N. B. 38. *Blount*, *Cowel.*

QUÆSTOR,

QUÆSTOR, among the Romans. See QUESTOR, *Cycl.* and *Suppl.*

QUAHVITLA, in botany, a name used by some authors for the tree from which the resin commonly called *gum copal* is procured. *Hernand.* p. 46.

QUAIL, *coturnix*, in ornithology, a bird of the gallinaceous kind. See COTURNIX and GALLINACEOUS.

The *quail* is a bird of passage, and with us frequents the corn-fields, and sometimes the meadows. They begin to sing in April, and they make their nests in the month of May, building on the ground.

Quails are to be taken by means of the call, during their whole woing time, which lasts from April to August. The proper times for using the call are at sun-rising, at nine o'clock in the morning, at three in the afternoon, and at sun set; for these are the natural times of the *quail's* calling. The notes of the cock and hen-*quail* are very different, and the sportsman who expects to succeed in the taking them, must be expert in both; for when the cock calls, the answer is to be made in the hen's note; and when the hen calls, the answer is to be made in the cock's. By this means, they will come up to the person so that he may, with great ease, throw the net over them and take them. If a cock-*quail* be single, on hearing the hen's note he will immediately come; but if he have a hen already with him, he will not forsake her. Sometimes, tho' only one *quail* answers to the call, there will three or four come up; and then it is best to have patience, and not run to take up the first, but stay till they are all entangled, as they will soon be.

The *quail* is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings they will often fly instead of running to the call; and in this case, it is best to let them go over the net, if it so happens that they fly higher than its top, and the sportsman then changing sides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a small leather purse, about two fingers wide, and four fingers long, and made in the shape of a pear; this is to be stuffed half full of horse-hair, and at the end of it is to be placed a small whistle, made of the bone of a rabbit's leg, or some other such bone: this is to be about two inches long, and the end formed like a flageolet, with a little soft wax. This is to be the end fastened into the purse, the other is to be closed up with the same wax, only that a hole is to be opened with a pin, to make it give a distinct and clear sound. To make this sound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax, then the purse is to be pressed, and the finger is to shake over the middle of it, to modulate the sound it gives into a sort of shake. This is the most useful call, for it imitates the note of the hen-*quail*, and seldom fails to bring a cock to the net, if there be one near the place.

The call that imitates the note of the cock, and is used to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire turned round and curled, and covered with leather; and one end of it must be closed up with a piece of flat wood, about the middle of which there must be a small thread or strap of leather, and at the other end is to be placed the same sort of pipe, made of bone, as is used in the other call. The noise is made by opening and closing the spiral, and gives the same sound that the cock does when he gives the hen a signal that he is near her.

QUALIFICATIONS *of members of parliament.* A knight, baronet, or any other under the degree of a baron, may be elected knight, citizen, or burgess. 4 Inst. 46, 47.

An alien, tho' made a denizen, cannot sit in parliament [a]; even persons naturalized by act of parliament are usually restrained from sitting as members [b]. Persons under the age of twenty-one years are not capable of being elected members of parliament. The election is void, and minors, tho' chosen, presuming to sit and vote, are under the same penalties as if they had sat and voted without being chosen [c]. [[a] 4 Inst. 47. [b] Vid. Stat. 12, 13 Will. III. 4 Ann, c. 8. and 1 Geo. I. [c] 7 and 8 Will. III. c. 25.]

None of the judges of the king's-bench, common-pleas, or barons of the exchequer, that have judicial places, can be chosen knights, citizens, or burgesses of parliament. 4 Inst. 47. None of the clergy can be elected knight, citizen, or burgess of parliament; because they are of another body, the convocation. 4 Inst. 47. Moor 783.

A person attainted of treason or felony is not eligible; for he ought, according to the writ, to be *idoneus, discretus & sufficiens.* 4 Inst. 48.

The king cannot grant a charter of exemption to any man, to be freed from election of knight, citizen, or burgess of the parliament. 4 Inst. 49.

For the incapacities of sheriffs, mayors of towns, and the reasons why they may or may not be elected knights, citizens, or burgesses, vid. 4 Inst. 48. *Bro.* Abr. Tit. Parliament. *Cromp.* Jurisd. 3 16. *Rushw.* Collect. Vol. I. p. 684. *Townsh.* Coll 185.

QUALITY (*Cycl.*)—QUALITY *of curvature*, in geometry, is used to signify its form, as it is more or less inequable, or as it is varied more or less in its progress through different parts of the curve. *Newton's* Meth. of Flux. and Inf. Ser. p. 75. *Maclaur.* Flux. Art. 369. See CURVATURE, Appendix.

QUAMOCLIT, in botany, the name of a genus of plants, the characters of which are these: the flower is of the monopetalous or one-leaved kind, and is funnel-shaped and divided into several segments at the end. From the cup there arises a pistil, which is fixed in the manner of a nail to the lower part of the flower; this afterwards changes into an oblong fruit, containing small seeds, usually of an oblong figure. See Tab. 1. of Botany, Class 2.

The species of *quamoclit*, enumerated by Mr. Tournefort, are these: 1. The finely divided pennated-leaved *quamoclit*. 2. The purple-flowered American *quamoclit*, with fingered leaves. 3. The six-leaved American *quamoclit*, with purple umbellated flowers. 4. The American *quamoclit*, with large heart-like leaves. 5. The purple-flowered American *quamoclit*, with large angular leaves. 6. The trifid, or ivy-leaved American *quamoclit*. 7. The pale red American *quamoclit*, with leaves like those of nightshade. *Tourn.* Inst. p. 116.

Quamoclit differs from bindweed, or convolvulus, in the shape of the flower.

QUANDROS, a name given by the writers of the middle ages to a stone, to which they attribute great virtues, and which, they say, is found in the head of a vulture.

QUANTITY (*Cycl.*)—QUANTITY *of curvature* at any point of a curve is determined by the circle of curvature at that point, and is reciprocally proportional to its radius. *Newton* Meth. of Flux. and Inf. Series, p. 60. *Maclaurin's* Fluxions, B. 1. ch. 11. See CURVATURE, Appendix.

QUANTITY *of action.* See ACTION.

QUANTITY $\left\{\begin{array}{l}\textit{impossible,}\\ \textit{imaginary,}\end{array}\right\}$ See the article ROOT.

QUAPACHTOTOTL, in zoology, a name under which Nieremberg has described a bird, which, he says, imitates the human laugh. He says its body is eight inches long, and the tail as many; the beak of a bluish black, and bent and crooked; the breast grey and the belly black; the tail of a brownish black, and the wings, neck, and head of a yellowish brown. *Ray's* Ornithol. p. 298.

QUARRY (*Cycl.*)—In many parts of England we find sea-shells buried in hard stone, and under great beds of earth.

Near Broughton, in Lincolnshire, all the *quarries* abound with them. At the east end of this town there is a *quarry* of a soft stone, which they dig through to get at a bed of clay, which is of a peculiarly glutinous quality, and hardens like mortar in drying: this is used for cementing other stones together, and in this are innumerable fragments of shells of cockles, scallops, sea-echini, and corals; and among these fragments there are found some whole shells of their natural colours, and often wholly unburt; tho' some of them are bruised and pressed quite flat by the great weight of earth that lies upon them. On the south side of the town there is a *quarry* of a blue stone, which was doubtless in the times before the deluge a blue clay, of the same nature with that just mentioned. This contains in its body vast numbers of the same sorts of shells, and of many other kinds; but they are all so firmly bedded in the stone, that it is not easy to get them out whole: but there is this very remarkable, that they only lie in the superficial part of the stone, the stratum being very thick, but not one shell found in it beyond the depth of two foot from the surface.

The surface of this stratum of stone is not even and smooth, but is waved and ridged irregularly, like a bed of snow, or like the waves of the sea in the time of a small wind. This has just the appearance that the surface of a mass of half hardened matter must have, if the wind blew fiercely upon it from one quarter; and by the direction of these undulations, it is easy to see from what quarter the wind blew at that time. In that part of the stone which forms this undulated roughness, there are as many shells as any where else; and these lie partly buried and partly standing out of the stone, just as we see the fresh water shell-fish lie half in and half out of the mud of the bottom of a pond or river that is dried up in summer.

It is very observable, that in this case, as much of the shell as is within the stone is perfectly well preserved, and as hard as stone; whereas that part which stands out is either wholly decayed, or at the best of the nature of a rotten shell, which falls to pieces on being touched with the hands. The part of the shell within the stone is usually converted into a mass different from the shell in all things but figure; but that which stands out always preserves the true texture of the natural shell, and is made up of many flakes and crusts as the natural shells of the kind to which it belongs are.

Among the shells buried in the substance of the stone, some have their shell perfect on them, others have only a thin crust of a whitish stony matter in the place of it, and others are wholly naked, and have no shell nor any covering at all: these are properly only casts of stone in the places where shells once were, all the matter of the shells themselves having been dissolved and washed away. In some of these there is a thick white substance in the place of the shell, between the cast and the bed of stone: these come out the most easy and perfect of

of any, and the matter which supplied the place of the shell remains fastened to the bed of the stone; others separate themselves very perfect after frosty nights.

Some of the cockles and other bivalves are found closed, others are found half open, as shell-fish naturally open their shells when deserted by the water. In these the cavity is always filled with the matter of the stratum, and both petrified together. In some places they lie in heaps together in the stone, and there they usually enter into and injure one another. Some are found shut so closely, that the matter of the stone-bed could not get into their cavity; and of these, some are at this time wholly empty, others are filled, or partly filled, with crystals and spars: these bodies must have been found in them only from the crystaline and sparry matter rising through the earth in vapour, and penetrating the very substance of the shells after their being lodged in the stone.

In this *quarry* there is also found a very remarkable shell, resembling a ram's horn, bent in the same manner, and with the same lineations. This is wholly different from the common cornu ammonis class, and has an operculum to close its mouth with, in the manner of the wilks and other such shells. This operculum is often found entire with the shell, or near it, in the same bed of stone.

This species of fossile shell is found in prodigious numbers together, and usually lies near the surface of the bed of stone, a part being buried in the stone, and a part standing out of it; many of them stand more than half way out, and the shell of these is so much more durable than that of the common kinds, that it is usually very firm and strong, even in such places where the other kinds moulder all away. These are usually found entire, but in some places they are crushed flat, and otherwise bruised and injured.

From these and the like observations made on the whole surface of the earth, and to great depths in its bowels, where ever men have dug on any occasion, arise plain proofs of the universality of the deluge; and from many of these observations it seems very plain, that in the time of the deluge the earth suffered great violence in many parts, that the bottoms of seas were in some places raised into mountains, and in others the tops of mountains sunk into seas, and the beds of shells still preserved in the fossile world were very often crushed and bruised by large masses of earth and pieces of rock thrown upon them.

Some think that it appears from the consideration of the *quarries* and strata of earth, *&c.* in the present world, that the antediluvian earth had seas and shores, mountains and plains, rivers and vallies, as ours has; and that waters from within the earth were let out upon its surface, and the whole crust of the then world subsided under these; that the contents of the seas, such as shells, corals, and the like, were after this tossed variously about over the surface of this drowned world, and left in different parts of it; and that this present earth afterwards partly arose out of the common flood, as islands are now formed in some seas, and partly was deserted by the waters, when called off again by the same almighty hand that brought it on: and as the strata of the earth were at that time soft, it is no wonder that matter then soft enough to let in the shells, *&c.* afterwards hardened, together with the shells it had received, into stone; and that in process of time, the stony particles eternally floating in the air and waters that pervade all the strata, deposited their small parts in the interstices of these shells, and finally the whole became stone.

It is no wonder that all sorts of marine productions, shells, parts of sea-fishes, corals, and the like, are found at this time in beds and *quarries*, in hills and mountains, and also in the bowels of the earth; for it is certain that they were produced in the antediluvian sea, and were either elevated with the hills and mountains in the time of the deluge, or they fell into holes, clifts, and chasms in the earth, which must be formed in vast numbers during the time of that terrible catastrophe, and in these they remain buried to this time; while others lodged on what was then the surface, became afterwards covered with more strata, deposited from what was still suspended in the waters, and so were buried at great depths from the present surface; when others rolling about among the last sediments of the same waters, while yet so unfixed as to be carried away with their violence, were finally left on or near the surface.

The *quarries* about Broughton seem to have been but little disturbed; and to have been originally the mud which formed the bottom of some large fresh water lake; for the shells found in greatest plenty of all there, are fresh water shells. These seem to have remained in their original mud while turned to stone; and the other shells, natives of the sea, which are buried there among them, seem to have been some of that immense number and variety that must have rolled along the bottom of that bed of waters; and the viscid nature of the clay detained many of these among its own proper inhabitants, and preserved them together in its strong state.

Beside the parts of animals, these *quarries* have vegetable matters also in them: the leaves and branches of whortles are not uncommon, and pieces of wood turned black and resembling charcoal are also found there. These have been preserved in the same manner with the leaves of fern on the slates of our coal-pits, and the plants and fishes found in hard stone in many of the German mines. Many of these vegetable remains are also found in loose nodules of stone resembling pebbles: these are not less easily accounted for than the rest; for it is not strange to conceive, that leaves and pieces of plants might be, in that general confusion, received into lumps of clay, which might afterwards be rolled into roundness by the motion of the water, and finally received into chasms of the earth, and there petrified. Phil. Trans. N°. 266, p. 685.

QUARTAN, (*Cycl.*) in medicine, the name of a species of intermitting fever, which returns upon the patient every fourth day, including the days of both the paroxysms, with a cold fit succeeded by a hot one. In this nature is endeavouring to relieve herself from some noxious matter adhering to some of the hypocondriac viscera, and to prevent the injury that might thence happen to the part, the *quartan* is, by authors, distinguished into the simple and the continual.

The simple *quartan* is the most regular of all the species of intermitting fevers: it almost constantly seizes the patient about four or five in the afternoon with a cold fit; but this is not so violent as in the quotidian or tertian, nor does it occasion any of the shaking of the limbs: it is, however very sensible, and usually lasts about two hours. This is preceded and accompanied by a general languor or faintness; but is not so frequently attended with vomitings as the other intermittents in the time of their cold fit, nor is there any tendency to a diarrhœa; but, on the contrary, the bowels are usually costive, not only on the day of the fit, but on the intermediate ones. The hot fit slowly succeeds the cold one, and is not so violent as in the tertian; but rather is troublesome from the sensation of driness it brings on, and is seldom succeeded by any sweating. The hot fit usually continues about four hours, sometimes six, and sometimes much longer than that in the first fits. During the heat the head is vertiginous, and afflicted with a heavy pain, not a very acute one. When the fit is over, the patient returns to tolerable good health again, and remains in that state for the two succeeding days, saving that he has a soreness in the limbs, and a weariness and general lassitude. The fit afterwards returns at the very hour it first came on at, and rarely varies at all from this: when it is observed to anticipate its usual time, there is just reason to fear its becoming continual. The persons most subject to *quartans* are those of a middle or advanced age; it rarely happens to young people unless epidemic, and of all other persons, those are most subject to it who live a sedentary life, and are of a melancholy disposition.

Causes of it. The general cause of a *quartan* is a morbid viscous matter, lodged in the hypocondriac viscera, and having communication by that means with the vena portæ. The liver, spleen, and glands of the mesentery are frequently the seats of this, rarely the primæ viæ. That these viscera are affected in *quartans*, is evident from the connection these diseases have with their other affections, such as dropsies, jaundice, and the like. The occasional causes are very frequently a quotidian or tertian fever improperly treated, obstructions or omissions of habitual discharges of blood, whether by bleeding, or by the menses, or hæmorrhoids; a heavy diet, without sufficient drink; a sudden chilling of the abdomen in a humid air, after the body has been violently heated. The principal time for these fevers is the autumn, whence they have been called by some *autumnal fevers*; and nothing more endangers their frequent return, than the abuse of strong liquors, or of acids, which coagulate the blood.

Prognostics. The tenacity of the morbific matter in these fevers, tho' in but a very small quantiy, yet renders them very difficult of cure. They often last many weeks or months, in spite of all medicines, and in some ages have been accounted the greatest scandal to physicians. When it seizes a person in the spring season, it is naturally of shorter duration; but when it comes on in its more usual season, the autumn, it generally holds the patient till the spring. *Quartans* are very apt to return upon people at the same season of the year at which they first seized them, especially when they have been but injudicially treated in the cure. It is often, indeed, rather suppressed than cured, and then returns usually at shorter periods, and often almost immediately on feeding heartily, which is commonly the case with those who have been freed from it by the bark injudiciously given.

It has been already observed, that this disease does not naturally tend to any sort of evacuation, and when such discharges are unnaturally provoked by medicines, as by vomits, purges, and violent sudorifics, it is easily changed into a hectic, or some other dangerous chronic malady. A *quartan*, when properly cured, usually carries off with it all tendency to hypocondriac complaints, to which the patient may before have been subject; but, on the contrary, when improperly suppressed, it too often brings on schirrosities of the liver and spleen, and of the mesariac glands, with œdematous swellings, hectics, asthmas, and other complaints.

A violent appetite after the fit of a *quartan*, or a tertian fever, is a sign that the disease will be very difficult of cure. Eruptions on the skin in the time of *quartans*, usually presage the going off of the disease; and sometimes hard tumors, and bad ulcers in the legs and feet, come on during the time of the ill-

illness; these generally presage the going off of the original disease, but they have in themselves a worse complaint in the place of it: and it is observed also, that œdematous tumors, which have their rise from ill-cured *quartans*, are much more obstinate and difficult of cure than any others.

Method of cure. The use of the bark is now universal in all intermittents, and the ignorant as well as the judicious give it; but there are many authors who are greatly against the sole use of it in *quartans*. Stahl says, that in this case the mucous matter lodged in the hypocondric viscera, which is the cause of the disease, should be first attenuated and incided by the neutral and digestive salts, as vitriolated tartar and the like; and with the gums, as ammoniacum and sagapenum, with the roots of arum and pimpernel; and by diluents, which would also take off the obstinate costiveness of the bowels. That when the matter is by this means fitted for evacuation, it should be thrown off by purges and diuretics, such as black hellebore, mercurius dulcis, and the tartar pills; and afterwards the cure to be compleated by restoring the viscera to their due tone, by means of bitters and subastringents, as gentian, centaury, and the jesuit's bark given in small quantities. By this means cures are much more regularly and happily effected than by bark alone. *Junker*'s Consp. Med. p. 373--376.

Bartholine, in his medical observations, gives us a very remarkable instance of a cure performed on a person long afflicted with a *quartan*, and who had tried all the common methods in vain. He was advised by some body to drink plentifully of very new beer; he did so, and going to bed, sweat very largely upon it, and was absolutely cured by it.

Quartans have sometimes been cured by mercurials. Med. Ess. Edinb. abr. Vol. 2. p. 317.

The *quartan* ague is said to be cured by a medicine composed of euphorbium, resin of jalap, merc. dulc. and sugar.

Continual QUARTANS, in medicine, the name given to a species of compound fever, which has the paroxysms of a common *quartan*; but in which the heat never goes wholly off, but continues till the time of the succeeding fit. In all respects, except the regular returns of the paroxysms, this disease greatly resembles a hectic.

Signs of it. Every fourth day there is a regular paroxysm, which begins with a coldness and shivering: this, however, does not return exactly to an hour, as the simple *quartan* does in its fits; but usually the succeeding fit anticipates the time of the former. When the cold fit is over, there comes on a violent day-burning; the heat is much greater the first day than the succeeding ones, but continues in some degree till the fourth day, when the cold fit returns again, and the patient is seldom able to keep long together out of bed in the whole time. There is a continual thirst and driness of the mouth, and the saliva is very little in quantity and very frothy; the appetite is bad, and the patient usually has more inclination to salted and cold foods than any other; the head is disordered rather than aking, and there is a continual desire to sleep, but what sleep the patient has is troubled and unsound, and gives very little refreshment; the urine during the whole course of the disease, resembles that of hectical patients, and is reddish and turbid, depositing, after a time, a rose-coloured sediment.

Persons subject to it. This disease is frequently brought upon persons who have had a common *quartan*, by the injudicious treatment of that distemper, and particularly by the taking hot medicines in it before the approach of the fit; the too free use of astringents has also in many cases changed that disease into this. People of a middle or more advanced age are more subject to it than youth; and of these, such are principally seen to be afflicted with it as are of a melancholic habit and sedentary life.

Prognostics in it. This disease, tho' in itself less dangerous than many others, yet very easily changes, under improper management, into a hectic, and sometimes into a dropsy. This is the case not unfrequently when it is treated with large repeated doses of astringents; on the other hand, when it is treated with vomits and a hot regimen, it easily passes into an acute and dangerous inflammatory fever.

Method of cure. Toward the time of the fit there should be given powders composed of the digestive salts, such as vitriolated tartar, with crabs-eyes, saturated with lemon juice. So long as the heat continues violent, the person is to be kept quiet, and to drink plentifully of warm and weak liquors; and in the following days, when the heat is observed to be decreased, gentle purges are to be given, with gentle aperitives, and resolvents, such as the decoctions of dandelion and succory roots; and toward evening, a gentle dose of some anodyne, as the storax pill and the like. The common violent methods by vomits, bleeding, stimulating purges, and hot alexipharmics, have no place in the cure of this disease; but, on the contrary, violently disturb nature, and add to the complaints. Absorbents in large quantities are also to be avoided, least the viscid matter which is the cause of the disease should be increased by their effects: and when the patient is happily cured, he is not immediately to abstain from medicines, since relapses are very frequent. Digestives and stomachics taken for some weeks after, is the way to prevent them. *Junker*'s Consp. Med. p. 209, 401.

QUARTARIUS, a measure among the antients, being the fourth part of a sextary, and nearly equal to a quarter of a pint of our wine-measure.

QUARTATION, (*Cycl.*) in metallurgy, is the separation of silver from gold by means of aqua fortis; which is an operation that has something singular in it.

If silver and gold are mixed together into a mass, and the gold is not less than one third part of the mass in weight, the best aqua fortis poured upon it is not at all capable of dissolving the silver; but if you add more silver to this mass, by melting it again in the fire, with such a necessary addition of that metal alone as shall bring the gold in the mass to the proportion of less than one third of the whole, and suffer it to cool, then aqua fortis poured on it will corrode the silver from it: this is also by so much the more strongly performed, as the quantity of gold is less than in the proportion of one third of the whole mass; but experience has taught us, that aqua fortis dissolves silver mixed with gold quickly enough when the gold constitutes but one, and the silver three parts of a mixed mass of them: and in this case, if the solution is not too impetuously performed, the gold usually remains in such a proportion, in the same figure that the whole mass had before the separation of the silver by this menstruum; so that in this case, there is no reason to apprehend the gold's being torn into minute particles, and dissipated in some measure; tho' this can hardly be prevented when the silver exceeds the three quarter proportion, in regard to the gold in the mass. The artificers. therefore, always make it their study to observe very exactly this proportion of the gold being one fourth part of the mixture; and thence it is that the operation itself has been called *quartation*.

From this operation we may learn how fallacious the examination made with aqua fortis alone of the gold rubbed on the touchstone, must necessarily prove. *Cramer*'s Art. aff. p. 195.

QUARTER (*Cycl.*)—QUARTER; in corn measure, seems to have signified originally the fourth part of a ton in weight, or capacity. See WEIGHT.

QUARTER-*chord*, in mining, is seven yards and a quarter, which the miner hath cross-ways of his vein on either side, for liberty to lay his earth, stones, and rubbish on, and to wash and dress up his ore. *Houghton*'s compl. Miner in the Explan. of the Terms.

QUARTER *of a ship*, is that part of the ship's hull which lies from the steerage-room to the transom.

Close QUARTERS, in a ship, those places where the seamen *quarter* themselves, in case of boarding, for their own defence and clearing the decks, &c.

Fat QUARTER, in a ship. See FAT, *Cyl.*

QUARTER-*masters*, or QUARTEERS, in a man of war, those officers whose business is rummaging, stowing, and trimming the ship in the hold; to overlook the steward in his delivery of victuals to the cook; and in pumping or drawing oot beer, or the like. They also are to keep their watch duly, in conding the ship, or any other duty.

QUARTER-*point* of the compass. See POINT, *Cycl.*

QUARTER-*wind*, at sea, that which comes in abaft the main-mast shrouds, even with the *quarter* of the ship.

QUARTER, in the manege. To work from *quarter* to *quarter*, is to ride a horse three times in end upon the first of the four lines of a square; then changing your hand to ride him three times upon the second; and so to the third and fourth, always changing hands and observing the same order.

QUARTERS *of a saddle*, are the pieces of leather or stuff made fast to the lower part of the sides of a saddle, and hanging down below the saddle.

QUARTERS *of a horse*, are the shoulders and fore-legs, called *fore-quarters*; and the hips and hinder legs, called *hind-quarters*.

QUARTERS *of a horse's foot*, are the sides of the coffin, comprehended between the toe and the heel on one side and t'other of the foot. The inner *quarters* are those opposite to one another, facing from one foot to the other; and these are always weaker than the outside *quarter*, which lie on the external sides of the coffin.

QUARTER-*cast*. A horse is said to be *quarter-cast* when, for any disorder of the coffin, we are obliged to cut one of the *quarters* of the hoof; and when the hoof thus cut grows anew, it is called *new quarter*.

False QUARTERS, a cleft in the horn of a horse's *quarters*, extending from the cronet to the shoe, which voids blood, and occasions a great deal of pain, and makes the horse lame.

QUARTERING *the men*, in the sea language, the disposing of the ship's company at the time of an engagement in such a manner, that each may readily know where his station is, and what he is to do: as, some to the master, for the management of the sails; some to assist the gunners, to traverse the ordnance; some for plying the enemy with small shot; some to fill powder in the powder-room; others to carry it from thence to the gunners in cartridges, &c.

QUARTUM *par constringens*, in anatomy, a name given by Spigelius and some others to the muscle called by Albinus and Riolanus *orbicularis oris*; and by Cowper and some others, *constrictor labiorum*.

QUARTUS *hyoidis musculus*, in anatomy, a name given by

Vesalius, Fabricius, and many other anatomists, to a muscle now generally called the *coracohyoidæus*.

QUARTUS *oculum movens*, in anatomy, a name given by Vesalius to one of the muscles of the eye, called by some *rectus inferior*, and by others *humilis*.

It is the *depressor oculi* of Albinus, being one of the *quatuor recti oculi* of that author.

QUATERNA *folia*, among botanists. See LEAF.

QUATOTONI, in zoology, the name of an American bird of the wood-pecker kind, having a red crest on its head, and two white lines running down the sides of the neck to the breast. It is called by Nieremberg *picus imbrifœtus*.

QUATRICHROMA, in the Italian music, is what we call a *demi-semi-quaver*, thirty-two whereof make a bar in common time. See TIME, TRIPLE, and BISCHROMA.

QUAVITL, in botany, a name given by some authors to the cocoa-tree. *Hern.* p. 79.

QUAUHAYOHUATLI, in botany, a name by which some authors have called the tree whose fruit is the cassia fistula of the shops. *Hern.* p. 87.

QUAUHTZONECOLIM, in zoology, the American name for a bird called by most a *quail*, but esteemed by Nieremberg a species of partridge.

It is of the size of the European partridge, and of a brownish colour, and ornamented with a crest upon its head. There are also in America two other species of partridge much allied to this, the one with a yellow body, and black and white head; the other small and brown, and without a crest. *Ray*'s Ornithology, p. 304.

QUEEN *(Cycl.)*—QUEEN-*bee*, a term given by late writers to what used to be called the *king-bee*, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every swarm, and which is always treated with the greatest respect by the rest.

This is, indeed, the parent of the swarm, and from the fœcundity of this one female, a whole hive is easily and soon repeopled.

It is to be observed, that the autumn and winter seasons destroy a great number of the bees; so that a hive, which was full in the summer, is often found so thinly peopled before the end of winter, that the bees seem only a few inhabitants in a very large city: by midsummer again this same hive shall, however, be found so well filled with inhabitants, that there shall be a necessity of sending out a colony in the name of a new swarm, and yet the hive will remain as full as it can well hold. This increase might well appear very amazing, if all the remaining bees of the hive were supposed to be females, and to join in it; but how much more so when it must be acknowledged, that it is all owing to one female, and that this *queen-bee*, or bee-mother, alone, has given origin to such an immense progeny?

The form of this bee, and there being only one such in a hive, naturally led all who saw it into an opinion of something singular in its nature, and the antients determined that it must be the king over the rest: they made it an absolute monarch, and have supposed that all the business of the hive was done by its immediate orders; and that the several parties of bees allotted to work in the making the combs, in the filling their cells, in the stopping the crevices of the hives, and in carrying away the filth, *&c.* had all their several stations allotted them by this wise and provident monarch. This was giving great talents to the monarch-bee; but this was mere fancy, and it is plain, that if this creature rules, it is over a people who all perfectly well know their several business: but it rather appears, that there is no sovereignty at all, but that this creature is respected in a very high degree by the rest as the common parent of the whole nation.

There were not wanting among the antients, however, some who believed this large bee to be a female, and these pretend that she brought forth only females like herself, which succeeded her in her reign. They had a very different opinion as to the origin of the common bees, not supposing them generated of animal parents like themselves, but produced out of corruption, and born of the flesh of a bull or cow. Among the later writers this opinion, notwithstanding the sanction of the poet Virgil, has been laughed out of the world; yet it was long before the true origin of bees, even after this, was known. The author of the female monarchy, tho' well apprized of this great bee being of the female sex, yet supposed that she only produced young ones like herself; and pretended that the common bees copulated together for the production of other bees like themselves: this, however, has been since found to be wholly erroneous, the female, or *queen-bee*, giving birth to all, and these common bees being of no sex at all.

Many of the authors who have not given into the idle opinion of the bees being bred of putrid flesh, have yet given them an origin not less idle and ridiculous. They pretend that the bees are exempted from the pain of producing either eggs or young; and that their offspring are formed of the juices of flowers, the different kinds, as the drones, females, *&c.* owing their rise to juices of different kinds. These, and a number of other false notions, have been propagated in regard to bees; but their true origin could not well be found till we were in a condition to see what passes at certain times within the recesses of the hive, which is done by the use of that excellent invention the glass hive. By this, and by the help of dissections, we may easily inform ourselves perfectly of the true state of the case.

The parts of generation are the subjects of our enquiry for this purpose, and tho' the bodies of these animals are so small, these are usually sufficiently large to be distinguished, often taking up more room in the abdomen than all the other parts together. Thus, if the large long-bodied bee be opened, the abdomen will be found to contain vast numbers of oblong bodies, which any one acquainted with insects will easily distinguish to be eggs: vast numbers of these are large enough to be observable by the naked eye, but when the assistance of glasses is called in, there are discerned a vast number of other smaller eggs, which exceed all computation. It is easy to determine from this, that this creature, so long esteemed a male, is in reality a female, and is in condition to give birth to a very numerous posterity.

In order to distinguish this, however, a proper time must be chosen for the dissection, and the most proper of all is when the creature is just ready to deposit her eggs. This is in the months of April and May, and the most certain time of all is when she is in a hive where a new swarm have been received about ten days before: if she be dissected at other times, the eggs are less visible; and particularly in winter, there requires a good glass to shew the rudiments of them. This is a disagreeable experiment, indeed, because it is always the destruction of a future swarm; all the eggs we see in the dissected female being what would have produced bees to labour for our benefit.

When the body of one of the drones is opened, there is found, instead of these vast numbers of eggs, a part seeming proper for a male organ of generation; and in the abdomen a number of vessels running in several windings and contortions, and filled with a milky humour. These seem destined for the important use of impregnating the eggs in the belly of the female, and it is very natural to determine from this that these are the males.

The common bees, when dissected, at whatever time of the year, never shew the least marks of any sex at all. The intestines of these bees are found at times to be more or less distended with honey, and with rough wax; but there are never discovered any eggs, nor any of the winding seminal vessels, so that it is plain they have no share in propagating the species: and the observation of the swarms from time to time, with the assistance of glass hives, gives proof to what the dissections seem to make sufficiently certain without this evidence.

The female bee resides within the center of the hive, always living in one of the spaces between the combs; if she occasionally comes out to the surface, and is seen walking over the edge of a comb, she is to be well observed at those times; for her only business is the laying her eggs in some of the empty cells of that part of the comb, which done, she always retires again.

In order to see the female, or mother bee, employed in this operation, we are to observe in the morning hours, between seven and ten, what passes in a glass hive into which a swarm have been received a few days before. The speed with which the common bees labour in making their combs on this occasion is almost incredible, and they seem not only to labour to have cells to deposit their honey in, but to know that the parent bee is at this time loaded with eggs for the production of a numerous progeny, and that she has an immediate necessity of cells for the depositing them in. This necessity is so urgent, that she is often forced to deposit them in cells not yet finished; tho' the bees labour so vigorously, that they often will erect a whole large comb in one day. If the hive be narrowly watched at these times in the morning hours, the female bee will be soon found employed in her work, and will be seen dropping her tail by turns into several cells every day. If the combs be examined a day or two after this, they will also be found to contain the eggs; one of these is placed in each cell, and appears in form of an oblong white body, fixed either to the solid angle of the base, or to one of the angles composed by the rhombs which form the triangular base of the cell, and is always attached in such a manner, that it lies nearly in an horizontal position.

The flat glass hives are the most favourable for the making these observations, since in those the combs are so narrow and so numerous, that the whole is taken in view at a time, from one side or the other; and there are always several combs to be made choice of for the operation; in the morning hours of April and May, the female mother bee will be usually seen walking very soberly over one or other of these combs, attended by a guard of about twenty of the common bees, all placing themselves in such a manner, that their faces are turned toward her, and all paying her the greatest marks of homage and adoration. As she walks along in this state, she examines every cell as she passes over, and such as she finds yet empty, and fit for her purpose, she rests at; and introducing the hinder part of her body at the top, plunges it so deep in that her tail touches the bottom. Then she deposites one egg and no

more,

more, and this is at that time covered with a glutinous matter, which faſtens it to the place where it is laid: from this cell the female paſſes to ſeveral others, where ſhe depoſits her eggs in the ſame manner.

Some authors who have written of the polity of bees, have repreſented the time of the female bee's laying her eggs as a ſeaſon of feſtivity and rejoicing in the hive; but this does not at all appear to be the caſe, the few bees which attend her on this occaſion ſeem the only ones that know any thing of the matter, and their behaviour favours more of homage and reſpect than of joy: they are continually ſtroking and bruſhing her clean with their legs and with their trunks, and offer her from their own mouths the fineſt honey, when ſhe has occaſion for food. The reſt are all employed in their proper offices, and the work of the hive goes on as uſual; and, indeed, it is well that it does ſo, for this time of rejoicing would be of very bad conſequence to the affairs of the hive, if carried on as ſuppoſed, ſince the female bee is thus employed, more or leſs, during the whole ſummer months.

When the female bee has laid ſix or ſeven eggs, ſhe always takes a time of reſpite or repoſe; and during this time, the bees which form her levee are doubly buſy in their careſſes, ſome bruſhing her head and breaſt with their trunk, but ſeveral being always employed together to cleanſe the hinder rings of the body, which have been fouled by being thruſt into the cells. When this is done, ſhe begins again; but Mr. Reaumur obſerves, that he never could ſee a female lay more than ten or twelve eggs at one time: he ſuppoſes that his preſence diſturbed the creature, and finally drove her into the inner parts of the hive, where ſhe might continue her works in cells leſs expoſed. It is not difficult to compute the number of eggs which the female lays every day, from the ſwarm which is ready to leave the hive at the end of May: this ſwarm uſually amounts to at leaſt twelve thouſand, and as the hive out of which theſe depart is not the leſs peopled by their loſs, it is evident that they were all the produce of the eggs depoſited by the female in the preceding months of April, with a part of March, and a few of the firſt days of May. On a moderate computation on theſe principles it will appear, that the female bee cannot lay leſs than two hundred eggs every day, for a long ſpace of time together; and this, tho' ſeemingly a monſtrous increaſe, is yet much leſs than that of ſome other of the winged inſects, in one of which, a two-winged fly, that author counted no leſs than twenty thouſand living worms, all ready to be depoſited by the parent, and to become flies of the ſame kind.

It has been ſtrongly objected againſt this ſyſtem, that tho' the female bee lays eggs, ſhe is not the only one that lays; and many will not give up the opinion of the common bees alſo laying ſome eggs, tho' but a few in number; obſerving, that if each of theſe lay only four or five eggs, it would be enough to give birth to a whole ſwarm, without ſuppoſing that this prodigious fœcundity belonged to the female bee alone: but this is running into the old error of the female producing only females like herſelf; whereas if we obſerve the cells in which we ſee the female depoſit her eggs, we ſhall in the ſequel find the common bees produced from theſe eggs, and iſſuing out of theſe cells: this is a ſufficient proof to any fair reaſoner, ſince it appears very plain, that if the female produces them, they do not produce one another. It is alſo evident, that not only theſe common, or working bees, but alſo the drones, or male bees, are produced from the eggs of this ſame female; and there is this remarkable forecaſt in the female, that ſhe always depoſits the eggs which are to give origin to theſe, in peculiar cells, proper for the reception of the worms which are to be hatched from them. It is to be obſerved, in examining a hive, that there are always ſome combs, or ſome parts at leaſt of combs, the cells of which are much larger than thoſe of the other parts or combs: theſe large cells are deſtined for the reſidence of the larger worms, which are to produce the drones or male bees. It has been obſerved as a miraculous ſingularity by ſome, that the female bee always knows before hand, whether the egg ſhe is going to lay will produce a male or a common bee; and that according to this knowledge, ſhe never depoſits the eggs for a male in a ſmaller cell, nor that of a common bee in a large one; but there is, in reality, leſs wonder in this than is ſuppoſed, for the eggs of which the drones are to be hatched are much larger while in the body of the female than thoſe of which the common bees are to be produced, and the whole occaſion of this choice in regard to the placing of them is, that when the creature finds a large egg coming forth, ſhe ſeeks one of the large cells to depoſit it in; and when the common ſmall eggs are coming, ſhe contents herſelf with the common cells.

It is very natural to believe, that the female bee lays a third kind of eggs; and that beſides producing many thouſand common, or working bees, and many hundreds of the males or drones, ſhe ought to lay one egg at leaſt capable of producing a female like herſelf, which is to be the mother of a future progeny, and the *queen* of the preſent race; ſince without ſuch a one for their leader, the young brood would never leave the hive in nature of a colony, and ſettle themſelves elſewhere.

What we thus perceive ought to be the caſe, is alſo found in reality to be ſo, and the female, beſides the other kinds of eggs, is found by a ſtrict obſervation to lay alſo eggs of this kind. We might perhaps only expect one female bee to be produced for each ſwarm, but as nature has ſeemed every where prodigal in the manner of the increaſe of her works, ſo it is in this caſe alſo. What millions of ſeeds are produced on a common elm-tree, for one that ſtrikes and ſucceeds ſo well as to grow up to be a tree? And of the number of young produced from the ſpawn of a carp, how few live to the ſize of a parent? Thus it alſo is in regard to the female bees; nature, tho' it has allotted only one of this kind, as abſolutely neceſſary to the new ſwarm, yet has given abundance of chances for that one to ſucceed, by the female's uſually laying at leaſt ten eggs for the production of the female offſpring, and often not leſs than twenty: there are, indeed, ſome ſeaſons when not one female is produced; but in theſe ſeaſons there is no ſwarm going out from the old hive, the creatures being informed by nature, that they have no buſineſs for combs and cells when they can have no offſpring to rear in them.

The working bees are not only very obedient to, and very careful of their *queen*, or female parent; but they are alſo very ſolicitous about her progeny. This is very evident in the ſtructure of the cells, which they prepare for the reception of thoſe eggs which are to be hatched into females. It has been before obſerved, that they prepare larger cells for the eggs which are to become drones, or male bees, than for thoſe which are to produce workers like themſelves. The large cells deſtined for the drones are, however, of the ſame ſhape and figure with the others, differing only in ſize; but this is not the caſe with thoſe deſtined for the female offſpring: theſe are not only very large, but very clumſily contrived, for the ſake of ſtrength; their ſides being much thicker than thoſe of the reſt, and their figure oval. The bees are extremely ſparing of their wax on all other occaſions, but for the conſtruction of theſe royal cells, as they may not improperly be called, they are as remarkably profuſe: one of the royal cells will weigh more than an hundred and fifty of the common kind. The bees are no more ſparing of the room than of the materials in the conſtruction of theſe royal habitations: they are often placed near the center of a comb, and a vaſt number of other cells are deſtroyed for their baſe; often alſo they hang down from the reſt of the comb, in form of ſtalactitæ from the roofs of ſubterraneous caverns.

A cell of this kind, when firſt formed, repreſents an acorn cup; but it is ſoon lengthened beyond the poſſibility of retaining that figure, and it remains thus till the creature is hatched from the chryſalis or nymph ſtate, and comes out of it; after which the bees, to loſe no room in the hive, form other common cells upon it, and the only remaining mark of the female cell, is the appearance of a knot in the place where it once ſtood.

The number of cells deſtined to receive the eggs which are to produce female bees are ſo few, and they are commonly placed in ſuch cloſe parts of the hive, that there is no great probability of the ſeeing the female employed in laying her eggs in them: there is no reaſon to doubt the fact, however, ſince when we know that ſhe lays eggs for the production of the male and the working bees, there is no wonder that ſhe ſhould alſo lay ſome for the production of females like herſelf.

It might ſeem much harder to conceive how ſo vaſt a number of bees ſhould be produced from this one, as we know are produced from her; but when one of the females is opened, the vaſt number of eggs diſcovered in each of her ovaries makes the prodigious increaſe no way wonderful.

Swammerdam obſerved, that the number of veſicles in the ovary of the female bee, was aſtoniſhingly great; he eaſily counted an hundred and fifty in each ovary, and could count about ſeventeen eggs in each veſicle large enough to be diſtinctly viſible; each ovary contains, therefore, two thouſand five hundred and fifty eggs, and both ovaries five thouſand one hundred. When we find ſo many eggs at once diſtinguiſhable by their ſize, it will be eaſy to conceive, according to the common courſe of nature in the propagation of inſects, that there may be more than as many too ſmall to be yet diſtinguiſhable; and at that rate, the number of twelve thouſand bees, which is the quantity that compoſes a moderate ſwarm, is not wonderful for the product of the eggs of one female for one ſeaſon. *Reaumur*'s Hiſt. Inſ. Vol. X. p. 111—126.

QUEI, in natural hiſtory, a name given by the Chineſe to a peculiar earth found in many parts of the Eaſt.

It is of the nature of an indurated clay, and in ſome degree approaches to the talcs, as our ſteatites and the galactites do. It is very white and abſterſive, uſed by the women of China to take off ſpots from the ſkin, and render it ſoft and ſmooth, as the Italian ladies uſe talc of Venice. They ſometimes uſe the fine powder of this ſtone dry, rubbing it on the hands and face after waſhing. Sometimes they mix it in pomatum. *Kircher*'s China Illuſtrat.

QUEM *redditum reddit*, in law, an old writ which lay where a rent-charge, or other rent, which was not rent-ſervice, was granted by fine holding of the grantor. If the tenant would not attorn, then the grantee might have had this writ. Terms of law.

QUEMI, in botany, a name ufed by fome authors for the nigella, or geth. *Ger.* Emac. Ind. 2.

QUERCERA, in medicine. See EPIALOS.

QUERCUS, the *oak*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the catkin kind, and is compofed of a great number of apices affixed to an axis by flender capillaments, and ftanding in thick clufters. Thefe are male or barren flowers, and the embryo fruit grows in other parts of the fame tree: thefe finally ripen into acorns furrounded with their cups, and containing a kernel which readily fplits into two parts. To thefe characters it is to be added, that all the *oaks* have finuated leaves.

The fpecies of *oak*, enumerated by Mr. Tournefort, are thefe: 1. The broad-leaved *oak*, with fhort pedicles, called by authors the *male-oak*. 2. The broad-leaved *oak*, with longer pedicles, called by authors the *female-oak*. 3. The ever-green broad-leaved *oak*. 4. The common *oak*, with very long pedicles. 5. The fmall *oak*, called the *phagus* and *efculus* by the old writers. 6. The *oak*, with large acorns and echinated cups. 7. The *oak* with fmall acorns and rough cups. 8. The Burgundy *oak*, with rough acorn cups. 9. The dwarf *oak*, which feldom grows to more than a foot high. 10. The woolly-leaved *oak*. 11. The fmall gall-bearing *oak*. 12. The *oak* with prickly, not woolly leaves, producing fmall galls. 13. The fmaller prickly-leaved *oak*. 14. The dwarf gall-*oak*, with cluftered galls. *Tourn.* Inft. p. 82. See OAK.

QUERCUS *marina*, the *fea-oak*, in botany, the name of one of the broad-leaved dichotomous fea-fucufes.

It is not agreed among the late botanifts what was the *fea-oak* of Theophraftus; and the moft antient botanifts, Clufius and Cæfalpinus fuppofe it to have been a fpecies of the fhrubby coraline; but that feems by no means to have been the cafe, fince Theophraftus fays his *fea-oak* had a long, thick, and flefhy leaf, whence we may much more naturally conclude it to have been of the fucus clafs. *Park.* Herb. 294. Gen. 1378, &c. *Dale*, Pharmac. p. 56.

QUERFAA, in the materia medica of the Arabians, a name given by Avifenna and others to cinnamon, when gathered with the wood of the young branches.

It was a common practice in the early times not to ftrip the fmall bark from medicinal trees, but to cut off the little boughs and ufe them bark and wood together. This the Greeks called *xylo-cinnamomum*, or woody cinnamon, and the Arabians *querfaa*, *querfe*, or *kerfe*.

QUERQUEDULA, in zoology, the name by which authors call the teal.

This is the fmalleft of all the duck kind. Its beak is black, and its head and the upper part of its neck of a reddifh brown; but there runs on each fide of the head a green ftreak from behind the eyes quite to the back part, and between thefe there is a black fpot under the eyes; there is a white line which feparates the reddifh colour from the green. The lower part of the neck, the fhoulders, and the fides are very beautifully variegated with black and white ftreaks. The breaft and belly are of a dufky greyifh white. The wings have fome white in them, and the legs are of a pale brown. There is a black fpot on the rump in the male, which is wanting in the female. The head alfo in that fex is lefs beautifully coloured. *Ray's* Ornithol. p. 290.

QUERQUEDULA *criftata*, the *crefted teal*, a name given by Bellonius and fome others to a fpecies of duck, remarkable for a tuft of feathers of an inch and an half long, hanging down from the back part of its head, and thence called the *tufted duck*; but more known among authors by the name *capo negro*. *Bellonius* de Avib. See CAPO *negro*.

QUESTOR (*Cycl.*)—The *queftorfhip* was called the firft ftep of honour, and the *queftors*, who were generally employed in the provinces abroad, affigned to them feverally by lot, no fooner returned from their provincial adminiftration, than they took their places in the fenate; and from that time forward, from the rank of equeftrians, or what we commonly call knights, became fenators for life. *Middleton* of Rom. Senate. p. 6, 7. See SENATE and SENATOR.

QUI *tam*, in law, is ufed where an information is exhibited againft any perfon on a penal ftatute at the fuit of the king, and the party who is informer, when the penalty for breach of the ftatute is to be divided between them; and the party informing profecutes for the king and himfelf. *Finch* 340.

QUICKSILVER (*Cycl.*)—This mineral is frequently found native in the earth, in its own fluid form; fometimes lying in large quantities together in the accidental cavities of ftone, and running out in a ftream as the miners break the maffes: but this is lefs frequent; its more common appearance being in fmall parcels, and often in fingle globules, fcarce large enough to be feen by the naked eye, lodged in great abundance in the pores of a foft foffile ftone, of a pale bluifh colour, from which it is eafily feparated by pounding and wafhing. It is alfo found in fome places lodged in the fame manner in fome of the harder ftones, and in various fpecies of earths.

Tho' *quickfilver* be, however, often found native, yet we much more frequently find it in the form of an ore; its particles being penetrated by, and intimately mixed with fulphur, and the concrete being by no means to be known for *quickfilver* to the naked eye, but being a red mafs of a ftony hardnefs, called *cinnabar*: and we are very fure that it is *quickfilver* penetrated by fulphur that makes this ore, fince we are not only able to feparate *quickfilver* eafily from it; but by a mixture of *quickfilver* and fulphur, we are able to make a red ftony mafs perfectly the fame with this.

The cinnabar is of a different form and appearance, according to the quantity of fulphur it contains, being ufually ftriated, and that fometimes with broader, fometimes with finer ftriæ; and the quantity of *quickfilver* in this is very great, the richeft maffes containing fix parts *quickfilver* to one of fulphur; and the poorer ufually half. It is fometimes found in large and pure maffes, and fometimes in fmaller particles, lodged in different earths and ftones. Thefe are fometimes few in number and placed feparately, and fo of little value; but in other maffes they are placed very thick in congeries, and are then feparated by pounding and wafhing, and worked for *quickfilver*.

Befide this pure ore of *quickfilver*, there is another much lefs rich; but which is worked in fome places to confiderable advantage: as the former is a mixture of *quickfilver* and fulphur alone, this is a mixture of thofe two, and of many other fubftances, and appears in form of a moderately hard ftone, ufually of a dufky orange colour; but not rarely of a greenifh brown, and fometimes blackifh. This has very little brightnefs, and nothing of the ftriated texture of the cinnabar.

The manner of feparating *quickfilver* from its ores, is by pounding them, and wafhing off the fuperfluous matter by repeated affufions of water; then adding iron filings to the remainder, the whole is diftilled in large iron retorts, and the mercury comes over pure into the receiver. In fome places where the ore is very rich, they only powder it, and put it into long-necked earthen veffels, which they ftop with bundles of mofs: thefe they invert into other veffels buried in the ground, and then making a fire about them, the *quickfilver* becomes feparated and drains through the mafs into the underpots. *Hill's* Hift. of Foff. p. 627.

It is very difficult to bring *quickfilver* to the great teft of the burning-glafs, by which all the other imperfect metals are eafily tried; but with proper cautions fomething is to be learned of it by this means:

If *quickfilver* be expofed to the focus on a piece of charcoal, on a tile, or in a coppel, the effect is the fame, it very foon is wholly diffipated in form of a thick fmoak; but if precipitate *per fe*, that is, mercury calcined alone by a long digeftion on a flow fire, be placed in the focus, it feems at firft to melt and run, but immediately after is diffipated in a thick fmoak, leaving a fmall quantity of an extremely fine powder upon the tile, in form of a fhort down. This powder, on being continued in the focus, finally runs together into a yellowifh glafs; in feveral parts of which there may be diftinguifhed fmall white, fhining, metalline particles, which feem to be *filver*.

If the precipitate *per fe* be expofed to the focus on a piece of charcoal, it is feen to melt and run into fmall globules of pure mercury, which foon after begin to fume and are diffipated entirely. It appears, therefore, upon the whole, that there is in *quickfilver* an oil, which may be feparated by long digeftion over a flow fire; and that the matter diverted of that, is no longer mercury, but a mere calx or a red earth, this being properly the bafis of this metal; that this calx does not vitrify in the manner of the other calxes of the metals, being too volatile for that, and eafily flying off in the fire; and finally, that this oil of mercury is not different from the other oils, even thofe of the vegetable kind, fince common charcoal could fupply its place by means of its oil, and reftore the calx to running mercury again. As to the fmall remainder of earth, after the diffipation of the calx of mercury, which run into glafs with metalline fpecks, it is much to be queftioned whether it be not owing to fome impurity in the mercury. Mem. Acad. Par. 1709.

The mines of Friuli afford at prefent very large quantities of *quickfilver*, fome native, or virgin, which they call *jung-frau*, and obtain either out of natural beds in the rocks, or by wafhing the ore in which it lies difperfed in fmall globules; but the far greateft part is not vifible to the eye in the form of *quickfilver*, nor can be feparated from the ore without the help of fire. Kircher, in his Mundus fubterraneous, gives a moft frightful defcription of this mine; but it is not more terrible than others of the fame kind. It is remarkable, that the entrance into it is not high up in the hills, as is ufually the cafe; but upon a level ground, and in the ftreets of the town. This fubjects them to great inconveniences from water, but they have admirable machines for the draining it out again. The defcent is by ladders near ninety fathoms down.

There are no damps in thefe mines, but the mifchiefs of the mercury itfelf getting into the bodies of the workmen are much greater and more general, tho' not fo fudden, as the effects of the damps in our lead and coal mines, and the like places.

The elaboratory belonging to thefe mines has furnaces capable of working fifty retorts at a time. There are generally fixteen of thefe furnaces at work at once, fo that eight hundred retorts are the general number in conftant ufe.

The retorts ftand in double rows on each fide the furnace, a row of thirteen below, and a row of twelve above.

The antients all esteemed *quicksilver* a poison, and it must be allowed to have dismal effects; the unhappy people employed in preparing it seldom live more than three or four years, and then die miserably: and such as take it internally, or by way of unguents, without great care, often suffer for their imprudence.

Under proper regulation, however, it is a most powerful and noble medicine, opening obstructions, and attenuating viscid humors in the very remotest parts of the body.

The preparations of *quicksilver* now in use are, 1. Æthiops mineral. 2. Factitious cinnabar. 3. Corrosive sublimate. 4. Mercurius dulcis. 5. Mercurius calcinatus, commonly called *precipitate per se*. 6. White precipitate. 7. Red precipitate, or red corrosive mercury. 8. Coralline mercury. 9. Turbith mineral. See MERCURY, &c.

Water in which *quicksilver* has lain for some time, tho' insipid, is said by Van Helmont to destroy worms; and Mr. Boyle seems to recommend it as an innocent and effectual cosmetic. Works abr. Vol III. p. 345.

QUID *juris clamat*, in law, a writ that lies where I grant the reversion of my tenant for life by fine in the king's court, and the tenant will not attorn; then the grantee shall have this writ to compel him. Terms of Law.

QUIJUBATUI, in zoology, the name of an American species of peroquette.

It is of the size of a lark, and in general of a yellow colour. Its eyes are black, and its beak grey. The edges of its wings are of a dusky green, and its tail long and yellow. It is a very beautiful bird, and very easily tamed. *Marggrave's* Hist. Brasil.

QUIL, in zoology, the name of a small animal of the ferret kind, frequent in the West Indies, and famous for its combat with serpents. See the article QUIRPELE.

QUILAQUIL, in natural history, the name given by the people of the Phillipine islands to a very beautiful species of parrots, which is commonly found wild in the woods there. It is all over of a fine green colour, and is smaller than the common parrots, and has a broad black bill and black legs. It is a very wild bird, and will not learn any thing.

QUILLOBO, in botany, a name given by some to a species of ketmia, called also *quingombo*. See QUINGOMBO.

QUINA *folia*, among botanists. See LEAF.

QUINCE, *cydonia*, in botany, &c. See CYDONIA.

The fruit of the *quince* is astringent and stomachic, but its chief use in the shops is in the *syrupus cydoniarum*, or syrup of *quinces*, prepared from its juice with sugar, which is a very pleasant syrup.

QUINGOMBO, in botany, the name given by the people of Congo to a species of ketmia, distinguished by Mr. Tournefort by the name of the *ketmia Brasiliensis folio ficus fructu pyramidato sulcato*, the fig-leaved Brasilian ketmia, with a pyramidal sulcated fruit. See KETMIA.

QUINNET, in mining, the name of a tool used in the cleaving rocks by means of gunpowder. This is a sort of wedge fitted to the flat side of what is called the *gun*; that is, a cylindric piece of iron, only flatted in one part, to receive this, and drilled through. When a proper hole has been made in the rock by the borer, the powder is put in, and then the orifice being stopped by the gun, and that wedged in by this *quinnet*, the powder being fired by a train communicating with the hole drilled through the gun, exerts all its force on the rock, and splits it in several directions at one explosion. Philos Transf. N°. 167. See MINING.

QUINQUANGULAR-*leaf*, among botanists. See LEAF.

QUINQUEFOLIUM, *cinquefoil*, in botany. See CINQUEFOIL.

QUINQUENNES, in some old historians, a name given to a certain people of India, among whom the women began to bear children at five years old, and seldom lived to more than eight years. Pliny gives us this account, and Solinus, who repeats it from him, increases the miracle by telling us, that they were a nation of women who had no men among them.

QUINQUEPRIMI, among the Romans, the five principal men in the senate of every municipal town. *Pitisc* in voc.

QUINQUEREMIS, in the naval architecture of the antients, a name given to a galley which had five rows of oars. They divided their vessels in general into monocrota and polycrota; the former had only one tire of rowers, the latter had several tires of them, from two or three, up to twenty, thirty, or even forty; for such a vessel we have an account of in the time of Philopater, which required no less than four thousand men to row it.

Meibom has taken off from the imaginary improbability of there ever having been such a vessel, by reducing the enormous height supposed necessary for such a number of rows of oars and men to work them, by finding a better way of placing the men than others had thought of. The *quinqueremes* of the antients had four hundred and twenty men in each, three hundred of which were rowers, and the rest soldiers. The Roman fleet at Messina, consisted of three hundred and thirty of these ships; and the Carthaginian, at Lilybœum of three hundred and fifty of the same size. Each vessel was an hundred and fifty foot long. Thus an hundred and thirty thousand men were contained in the one, and an hundred and fifty thousand in the other, with the apparatus and provisions necessary for such expeditions as they were intended for. This gives so grand an idea of the antient naval armaments, that some have questioned the truth of the history; but we find it related by Polybius, an historian too authentic to be questioned, and who expresses his wonder at it while he relates it. *Meibom* de Trirem.

QUINQUEPARTITE-*leaf*, among botanists. See LEAF.

QUINQUERTIONES, among the Romans, an appellation given to those who had gained the victory in the *quinquertium* or *pentathlon*.

QUINQUERTIUM, among the Romans, was the same with the Grecian *pentathlon*, comprehending the five exercises of running, leaping, throwing, darting, and wrestling. See the article PENTATHLON, *Cycl.*

QUINQUINA (*Cycl.*)—The most accurate account we have ever received of the tree which produces the *quinquina*, or Peruvian bark, is from Mr. de la Condamine, who in travelling through some parts of America, chose the route of Loxa, where the finest bark is gathered, and where the greatest number of the trees are found; and taking instructions from Mr. de Jussieu, as to what enquiries were most necessary to be made, informed himself very much at large about it.

The finest bark, and the greatest quantity, he informs us, was gathered on Cajanuma, situated two leagues and an half to the south of Loxa; and this is the very place where the first bark that was sent into Europe was gathered. He found means to remain a night on his journey on this mountain, and in his return took a branch from one of the trees which had both flowers and ripe fruit on it, as is the case with this tree throughout the whole year, and this branch was the ground of his figures, as the observations he made in the journey were of his accurate account of the tree.

The natives reckon three species of bark, the reddish, the yellowish, and the white. The last of these has very little virtue, and the other two are nearly equal in goodness, tho' the world gives it in favour of the red. These two are the barks of trees which have no difference in their leaves, fruits, or flowers; and which even the people who are continually employed in the service cannot distinguish at sight, but pierce the bark with a knife, to see the difference, the yellowish being thus found to be tenderer and paler coloured than the other. The trees which produce these two sorts grow indiscriminately one by another, and the bark is gathered indifferently from both; and in drying the distinction between them becomes yet less visible, since both acquire a brownish colour.

The tree which produces the white *quinquina* has rounder and rougher leaves, the flower also is whiter, and the fruit larger, and its outer covering whitish. This tree usually grows near the top of the mountain, and is not found among the other kinds; they usually being found about the midway of the height, and principally in hollows, or in the more close or sheltered places. Some have suspected, that this difference of the trees which produce white, and the other barks, was only owing to the more cold and exposed situation it had on the top of the mountain; and thus much is well known as to the bark in general, that the warmer the place is where it grows, the greater are its virtues.

The *quinquina* tree never grows in the plains; it is a constant inhabitant of the mountains, and is easily known from the trees it grows among by its erect growth, and its height when of any considerable age, as it always carries its head above the rest. These trees are never found in clumps or clusters together, but always separate and single among other kinds. They grow to a very considerable size, when suffered to remain long enough; some are as thick as a man's body, but the more usual are about nine inches in diameter.

It is very rare, however, to find any large ones at this time on the mountain where the bark is gathered, the great demand for it having made them bark all the trees, and these having all perished by it; for the old trees never recover the barking, tho' the young ones frequently do.

They use no other instrument for barking the trees than a common knife, which the workman thrusts through the bark at as great a height as he can reach, and then bearing hard upon it, brings it down to the bottom, cutting all the way. If there be any difference, as some have pretended, between the bark that was at first imported, and that which we now receive, it must be wholly owing to the different ages of the trees it was then and is now procured from; that having been the bark of old trees, and there being now none but young ones: this gentleman having scarce seen any there that were thicker than a man's arm, or above twelve or fifteen feet high; and those which they cut young always throw out new shoots from the bottom.

In the times when the bark was first brought into use, the world preferred the thickest pieces, now they set the greatest value on the thinnest; but the latter preference is most reasonable; since it is not founded on fancy, but on the experiments made by the English and other nations of the different virtues, and the result of chemical analyses.

There was once an opinion, that there were certain seasons to be observed for the gathering the bark, and that it ought always to be done in the decrease of the moon; but experience

rience has ſhewed theſe to be idle opinions, and it is now gathered at all times if the weather be dry. When the bark is taken off, it is laid in the ſun till perfectly dry; the omitting this circumſtance, and packing up the bark while moiſt, has occaſioned it often to become mouldy, and ſpoil, and the merchants have attributed this to the taking it off in a wrong time of the moon, when it was wholly owing to its being put into the ſkins while too moiſt.

The leaves of the *quinquina*-tree ſtand on pedicles of about half an inch long: they are very ſmooth and gloſſy, and of a beautiful green; but ſomewhat paler on the under ſide than the upper. They are perfectly ſmooth at the edges, and are of an oblong figure, pointed at the end, and rounded at that part which joins to the ſtalk. They are from two and an half to three inches in length, and from an inch and an half to two inches in breadth. The middle rib of the leaf is rounded on the upper ſide, and is uſually of a reddiſh colour, eſpecially towards the pedicle; and the whole leaf often becomes red, when perfectly mature. All the ſmall branches towards the top of the tree terminate in one or more cluſters of flowers, which, before they are open, reſemble in their ſhape and their bluiſh grey colour, thoſe of the common lavender. Mem. Acad. Scienc. Par. 1738.

When theſe open, they change their colour: each ſtalk that ſuſtains one of theſe cluſters of flowers ariſes from the ala of one of the leaves, and divides into a great number of ſmall branches, each of which is terminated by a cup divided into five parts, which ſuſtains a flower reſembling that of the hyacinth. It is compoſed of a pipe of three quarters of an inch long, which at the end is divided into five, and ſometimes into ſix ſegments. Theſe are of a beautiful deep red within, and are ſerrated round the edges in a very elegant manner. From the bottom of the tube of the flower there ariſes a white piſtil, terminated by a long green head; this ariſes above the level of the ſegments of the flower, and is ſurrounded by five ſtamina, which ſuſtain apices of a pale yellow colour: theſe remain hid within the flowers. The tube is of a dirty red, and is covered with a ſort of whitiſh down. When the flower is fallen, the cup ſwells in the middle into the form of an olive, which by degrees grows into a fruit divided into two cells, which in drying become ſhorter, and the whole fruit rounder than in its natural condition.

This fruit finally opens longitudinally into two capſules, ſeparated by a membranaceous ſeptum, and coated by a thin yellowiſh ſkin; the ſeeds are of a reddiſh colour, and in ſhape are flattiſh, and, as it were, foliaceous; they are not more than a twentieth part of an inch in diameter, and are thickeſt in the middle, becoming thinner at each ſide. The plantula ſeminalis lies in the very center of the ſeed, between two pellicles: theſe ſeeds, which reſemble in ſome degree thoſe of the aſh in miniature, are faſtened in the manner of ſo many ſcales to a placenta of an oblong figure, pointed at the two extremities, ſo as ſomewhat to reſemble a ſeed of the common oat, but that it is longer and flatter. This is joined to the ſeptum, and has on that part a longitudinal furrow; but on the other ſide is convex, and ſomewhat rough all over. Mem. Acad. Scienc. Par. 1738.

By this deſcription it appears, that they were very ignorant of the nature and characters of this tree, who, in its firſt knowledge among us, called it a ſpecies of ſebeſten.

The uſe of this febrifuge ſeems to have been very long known to the natives, and their manner of taking it was by pounding the bark, and laying it to infuſe in water, and drinking the infuſion; their hatred to the Spaniards, their conquerors, made them keep it a long time a ſecret from them; and when the thing became known among the inhabitants of Loxa, it ſtill remained a ſecret to the reſt of the world, and its great value was never generally known till the year 1633; when the lady of the viceroy of Peru, the counteſs de Chinchon, being long ill of an intermittent fever, which would give way to none of the known remedies, the corregidor of Loxa ſent to the viceroy a quantity of the *quinquina* bark, which he aſſured him would cure the lady, tho' all other means had failed. Upon this the corregidor was ſent for to Lima, and after having given the medicine to many other perſons with ſafety and ſucceſs, the lady at length took it, and was cured. She immediately on this ſent for a large quantity of the bark, had it powdered, and herſelf diſperſed it to thoſe who had occaſion for it; whence it obtained the name of the *counteſs's powder*: but this lady being ſoon tired of the office, gave it in charge to the jeſuits; and they continuing to give it to the ſick with the ſame ſucceſs, it then was called the *jeſuits powder*. Theſe reverend fathers ſoon found means to ſend a quantity of it to Cardinal Lugo, who diſperſed it with the ſame ſucceſs at Rome; and after him the apothecary to the college gave it gratis to the poor with the ſame good effects, and under the name of the *jeſuits* or the *cardinal's powder*: afterwards the better ſort were made to pay its weight in ſilver for it, to defray the expences of its importation, while the poor ſtill had it gratis. Lewis XIV. at that time dauphin of France, was cured by it of a fever which had not given way to other medicines.

In the year 1640, the count and counteſs of Chinchon being returned to Spain, their phyſician, Juan de Vega, who brought a great quantity of it over with him, ſold it at a conſiderable price; and ſoon after this, large quantities were ſent over by the galleons, but the great demands from Europe cauſing the inhabitants of Loxa to adulterate it with other barks, it had like to have loſt part of its juſt praiſe. The *quinquina*-trees are found at this time on all that chain of mountains adjoining to Cajanuma, and in many other parts of America.

QUINTAIN, (*Cycl.*) the name of an old Engliſh ſport, intended for a trial of the agility of men on horſeback. It is loſt in many parts of the kingdom, but was ſtill in uſe at Deddington, in Oxfordſhire, in the time of Dr. Plot. The method of performing it is this:

They firſt ſet up a poſt perpendicularly in the ground, and then place a ſlender piece of timber on the top of it, on a ſpindle, with a board nailed to it at one end, and a bag of ſand at the other. Againſt this board they antiently rode with ſpears, but afterwards only with ſtaves, which violently brought about the bag of ſand; ſo that if they did not make good ſpeed away, it ſtruck them on the neck or ſhoulders, and ſometimes knocked them down. The great point aimed at was always the breaking of the board, and he that did that, was accounted the greateſt maſter.

It ſeems to have had its name from the Latin *quintus*, fifth, as one of the antient ſports uſed every fifth year among the Olympian games; or becauſe it was the ſport of the fifth or laſt day of theſe games. *Plot's* Oxford. p. 204.

QUINTESSENCE (*Cycl.*)—QUINTESSENCE *of wine*, a term uſed by Glauber to expreſs an eſſential oil of wine, which he directs to be made by a careful diſtillation, and which he is very fond of, as having a power to meliorate, improve, and even to ſpecificate the poorer wines into the nature of thoſe from which it was obtained.

This is one of the ſchemes of Glauber, generally eſteemed an impracticable one, tho' very plauſible in theory; but tho' in general there is a diſagreeable flavour in the *quinteſſence* drawn after his method, which is different from the true flavour of the wine, and ſpoils the liquor it is added to; yet by proper care there is a poſſibility of ſucceeding ſo far as to render this extraneous flavour almoſt imperceptible, and produce an oil that will mend poor wines extremely, and give a truly vinous flavour to ſuch as are in themſelves taſteleſs: but whatever may be done by this method, may alſo be done with much more certainty, and much leſs trouble, by the concentration of wines by freezing. This may be eaſily practiſed in the wine countries; and by this means Burgundy, Champaign, and other the moſt valuable wines, may be reduced into thick extracts and robs, by the means of which wines may be made in England; a very ſmall quantity of theſe concentrated wines being ſufficient to convert the whole of any of the poor taſteleſs and inſipid wines, which are of themſelves of little or no value, into the very wine from which the rob was made, and that in ſuch perfection, that the niceſt judge cannot find out the difference.

Theſe robs of wine made and preſerved upon the ſpot, would alſo be of infinite uſe in the wine countries, as they might be kept to improve the wines of bad years. *Stahl*, de Concentr. Vin. *Shaw's* Chem. Eſſ.

QUINTUS *femoris*, in anatomy, a name given by Fallopius and many others to one of the muſcles of the thigh, now called the *pſoas magnus*. See PSOAS.

QUINTUS *oculorum*, in anatomy, a name given by Veſalius and ſome others to one of the muſcles of the eyes, more expreſſively called by others *obliquus ſuperior oculi*, and *opifex circumgyrationis oculi*.

QUINVA, in botany, a name by which ſome authors have called the amaranth, or cockſcomb. *Moriſon*, Hiſt. Vol. II. p. 602.

QUINZY, or ANGINA (*Cycl.*)—This is defined by medical writers to be an inflammatory ſtaſis of the blood about the throat, in which nature ſeems to have aimed at the diſcharging part of the load of a plethora, either by an hæmorrhage of the noſe, or by ſpitting of blood; but effecting neither, the *quinzy* is produced.

Authors have divided the *quinzy* in general into two kinds, the true and the ſpurious. The true *quinzy* is that in which the tumor is internal, and is attended with a fever. The ſpurious is that in which the tumor ſhews itſelf more outwardly, and is not attended with a fever.

The antients alſo divided the *quinzy* into four other kinds, which they called by as many names.

1. The *cynanche*. In this the tumor neither manifeſts itſelf outwardly nor inwardly, but is attended with a very violent fever.

2. The *paracynanche*. This was the name given it when the tumor appeared externally in the muſcles of the larynx, and was highly inflammatory.

3. The *ſynanche*. In this kind the tumor appears externally alſo, and there is a leſs difficulty of breathing; but a greater of ſwallowing than in the other kinds.

4. The *paraſynanche*. This name denoted an inflammation of the muſcles of the pharynx, attended with a fever.

We at this time diſtinguiſh alſo the *quinzy* into the idiopathic and ſymptomatic. The firſt, where it is itſelf the diſeaſe, and owes its origin only to a plethora. The ſecond, where it is

is but the accidental ſymptom of an inflammatory fever, or ſome other diſeaſe about the time of its criſis.

Signs of a quinzy. The firſt ſymptom of this diſeaſe is a difficulty of ſwallowing, joined with a tumor in the throat, and a ſenſation of a pricking pain; to theſe ſymptoms there ſucceeds an inflammation and violent heat in the fauces: and in a few hours theſe ſymptoms increaſe to ſo great a degree, that the patient becomes unable to ſwallow; the tongue ſwells violently, and the veins appear black and tumid under it, the face becomes red and tumid, and the temporal veſſels are diſtended, and the eyes become ſwelled and ſeem as if they would ſtart out of the head; then reſpiration becomes very painful, and there is danger of abſolute ſuffocation. The hands become pale and cold to the touch; and the fleſh is at times very hot, and ſoon after very cold again; and in the progreſs of the diſeaſe the patient is uſually found to be very low ſpirited.

The idiopathic *quinzy* ſeldom happens to any except young people of a remarkably plethoric habit of body; and people are moſt ſubject to it who have been uſed to frequent bleedings at the noſe, and who live ſedentary lives, and feed high. The moſt frequent cauſes of this diſeaſe are a ſuppreſſion of hæmorrhages by the noſe, a ſudden cooling of the body after exceſſive heat, drunkenneſs, an improper uſe of ſtrong ſternutatory powders, violent and loud calling, and finally, luxations of the neck.

As to the ſymptomatic *quinzy*, the moſt common of all cauſes of it is the improper uſe of bleeding in acute fevers and other inflammatory diſeaſes.

Prognoſtics in quinzies. The more violent the attack of this diſeaſe is, the greater is the danger with which it is attended. The ſpurious *quinzy* is always more favourable than the true one, and the mildeſt of all the kinds is the paracynanche, as the cynanche is of all others the moſt fatal. Thoſe who die of this diſeaſe rather die of convulſions than of ſuffocation. When the matter cannot be diſcuſſed, there uſually happens a ſuppuration; and in this caſe the event is very dubious and uncertain.

Method of cure. Immediately on the attack of the diſeaſe, a clyſter is to be given. Warm urine or brine will ſerve the purpoſe, or, if equally ready, the pulp of colocynth, or aloes ſhould be boiled in the liquor. After this there muſt be a large quantity of blood taken from the arm, or foot, which is by ſome eſteemed much better; and if the ſymptoms do not then remit, the raninæ venæ are to be opened ſoon afterwards. In a milder attack it is not neceſſary to bleed in the time of the fit, but the common remedies for allaying the inordinate emotions of the blood take place; ſuch as powders of nitre, crabs-eyes, and cinnabar, and on occaſion a gentle anodyne or opiate may be added to theſe; as a ſmall doſe of the ſtorax pill, or the like. Theſe things are alſo to be given in the more violent caſes, and through the whole courſe of the diſtemper, provided that the difficulty of ſwallowing does not prevent it. After bleeding and theſe powders, the uſe of gargariſms is very great: of theſe there are three kinds; 1. The reſolvent or nervine and diſcutient: theſe are prepared of orrice and elecampane-root, hyſſop, chamæmile flowers, and anniſe and caroway ſeeds, and the like. 2. The lenient, or demulcent, which ſerve to allay the inflammatory heat: theſe are prepared of the mucilaginous and cooling things, as quince-ſeeds in red roſewater, with ſyrup of raſpberries, mulberries, and nitre, with jews-ears and album græcum, which two laſt are looked upon by many as ſpecifics. And, 3. The aſtringents: theſe are made of the traumatic herbs, ſuch as mouſe-ear, ſelf-heal, and the like, with biſtort and comfry-root, pomegranate rind, galls, terra Japonica, and alum.

The gentle aſtringents are to be firſt uſed, and it muſt be with great caution that we proceed from thoſe to the more powerful ones. While theſe are uſed internally, the external uſe of emolient and diſcutient plaiſters is alſo to be brought in; ſuch are melilot and diachylon with the gums: and in caſes where the heat is violent, inſtead of plaiſters, linnen-cloths wetted with ſpirit of wine and camphor, with a little ſaffron, are to be applied. If all theſe things fail, and the ſwelling riſes and breaks, the patient is always relieved by the breaking, and is to uſe afterwards, by way of gargariſm, wine ſweetened with honey of roſes. The bowels are always to be kept looſe by glyſters, or gentle purges; and finally, where the danger of ſuffocation is imminent, bronchotomy is the laſt relief. *Junker*, Conſp. Med. p. 154, ſeq.

Beſide the common occaſions of this diſeaſe, we have in the philoſophical tranſactions an account of a ſtone breeding at the root of the tongue, and cauſing one. The patient was almoſt choaked, and the tumor, which was large outwardly, tho' not tending to ſuppuration, yet was ready to break within, and ſhewed matter ready to be diſcharged. On breaking it with the finger, there iſſued out above a quarter of a pint of matter, and with it a ſmall ſtone, very hard, and of the ſame nature and ſubſtance with thoſe formed in the kidneys.

In this diſtemper, beſides high bleeding, ſome recommend a gargariſm compoſed of ſublimate mercury, half a drachm; cream of tartar, two drachms; diſſolved in a pint of ſpring water. Med. Eſſ. Edinb. abr. Vol. II. p. 431.

We have the hiſtory of an uncommon *angina*, or *quinzy*, by Mr. Monro in the medical eſſays of Edinburgh abridged, Vol. II. p. 400.

QUIRICIA, a name given by ſome to the ſtone called *quiris* by the generality of writers. See QUIRIS.

QUIRINACIUM *opium*, in the materia medica, a name given by ſome to the gum we know by the name of aſſa fœtida.

It is a barbarous phraſe of the middle ages, and is founded on the name ὄπιον κυρηναικόν of the Greeks, which expreſſed the Cyrenean gum, that being the name they gave to the original aſſa, which was a ſweet-ſcented gum, not the ſtinking aſſa-fœtida. We call both theſe aſſa, but the Greeks diſtinguiſh the ſtinking kind by the name *ſcordolaſaron*. See the article ASA.

QUIRINUS *lapis*. See QUIRIS.

QUIRIS, a name given by the writers of the middle ages to a ſtone famous among them for its imaginary virtues, but of which they have left us no deſcription.

They call it alſo *quirinus* and *quiricia*, and pretend, that if put under any one's pillow, it will cauſe them to divulge all their ſecrets by talking in their ſleep.

QUIRPELE, in zoology, the name of a ſmall animal, called by ſome authors the *Indian ferret*, *viverra Indica*, and by others *quil*.

Garcias and ſome authors give very remarkable accounts of the enmity this creature has to ſerpents of all kinds. They tell us, that when this little creature intends an attack upon one of theſe animals, it firſt prepares againſt danger by gnawing a quantity of the root of the *lignum colubrinum*, or ſnake-wood; and when it has thoroughly impregnated its *ſaliva*, it wets with it firſt its fore-feet, and with them daubs over its head and its whole body; and that thus prepared, it boldly attacks the ſnake, and never leaves off till it has killed it. Garcias aſſures us, that many of the Portugueſe have been eye-witneſſes of theſe combats.

It is probable enough, that this creature may attack a ſnake when thoroughly hungry, knowing its fleſh to be good food; but I fear the ſtory of the antidote is to be ſuſpected. *Ray's* Syn. Quad. p. 197.

QUITY, in botany, a Braſilian name uſed by ſome authors for the ſapindus, or ſoap-berry tree of the Weſt Indies. *Margg:* Hiſt. Braſil. p. 113.

QUOD (*Cycl.*)—QUOD *ei deforciat*, in law, a writ for tenant in tail, tenant in dower, by the courteſy, or for term of life, having loſt their lands by default againſt him that recovers, or his heir. Reg. orig. 171. Stat. Weſtm. 2. c. 4. *Cowel*, Terms of Law.

QUOD *permittat*, in law, a writ that lies where a man is diſſeiſed of his common of paſture, and the *diſſeiſor aliens*, or dies ſeiſed, and his heir enters; then if the diſſeiſee die, his heir ſhall have this writ.

QUOIL (*Cycl.*)—*Weather*-QUOIL, at ſea. See WEATHER.

QUORUM (*Cycl.*)—QUORUM *nomina*. In the reign of King Henry VI. the king's collectors, and other accomptants, were much perplexed, in paſſing their accounts, by new extorted fees, and forced to procure a then late invented writ of *quorum nomina*, for the allowance and ſuing out their quietus, without the allowance of the king. *Blount*.

QUOTIDIAN, (*Cycl.*) in medicine, the name of a ſpecies of fever which attacks the patient every day, at firſt with a chilneſs, and with a febrile heat ſucceeding this, by which nature commonly attempts to eaſe herſelf of the load of ſome morbific matter which uſually adheres in the primæ viæ. This differs greatly from the continual *quotidian* fever. See the article *Catarrhal* FEVER.

It is diſtinguiſhed from the double tertian by this, that the *quotidian* regularly obſerves its times of attack and of duration every day; but in the double tertian, the ſingle fits do not correſpond one with another, but only the alternate ones, that is, the paroxyſm of the third day correſponds with that of the firſt, that of the fourth with that of the ſecond, and ſo on.

Signs of it. This fever uſually attacks the patient in a morning, and moſt frequently about ſix or ſeven o'clock. The firſt ſymptom is a very violent chilneſs or coldneſs, which uſually laſts about an hour, and is attended either with a vomiting, or with a diarrhœa, or both. This cold fit is ſucceeded by a violent hot one, in which there is an intolerable thirſt and pain of the head. The whole duration of the fit is uſually ſix hours, and when the heat remits a little of its violence, then ſweats uſually come on. This returns regularly at the ſame hour the next day, and ſo on, unleſs diſturbed by any means; in which caſe, it anticipates or poſtpones the accuſtomed time.

Perſons ſubject to it. This is the leaſt frequent of all the intermittent fevers. Perſons of phlegmatic habits are more ſubject to it than thoſe of any other temperament; and it ſeizes old people oftner than young, and women much more frequently than men.

Cauſes of it. The firſt cauſe of this diſeaſe is a viſcous and mucous matter lodged in the primæ viæ. This is often attended with a ſpiſſitude of the blood in the vena portæ. The occaſional cauſes which bring on this ſpiſſitude of the blood and foulneſs of the primæ viæ, are a coarſe and thick diet, a ſedentary

dentary life, and a natural turn to melancholy. The caufes of this, and of the tertian, feem to be the fame, only that in this they are ftronger.

Method of cure. The general cuftom of curing intermittents by vomits and the Peruvian bark alone, is cenfured by Stahl, and many other writers, as being faulty in two extremes; the vomiting throwing off the offending matter with too much violence, and the bark locking it up in the body. Vomits, when injudicioufly given, often give violent reachings, without bringing up any part of the matter of the difeafe; and the bark, and other aftringents, bring on obftinate coftivenefs, flatulencies, ftraitnefs of the breaft, and many other diforders; fuch as, the jaundice, dropfy, œdematous fwellings, and many other the like complaints, which often fucceed the too large or injudicious ufe of it: for this reafon, thefe authors prefer a regular method, by inciding the tough matter in the primæ viæ, with tartarum vitriolatum, and the like, then the giving a gentle emetic; after this, gentle diaphoretics and diluents, fuch as all warm and weak liquors; and afterwards ftrengthening the ftomach and bowels by bitters and fubaftringents, among which the bark has its place, tho' in fmaller quantities than when trufted to alone in the ufual way. *Junker*'s Confp. Med. p. 360.

R.

RABBIT, *cuniculus*, in zoology, a well known animal of the hare kind. See the article LEPUS.

The female, or doe *rabbit* goes with young thirty days, and then she kindles; and if she take not buck presently she loses her month, or at least a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in some places much sooner; and they continue breeding very fast from the time when they begin, four, five, six, or seven times a year being common with them. They have usually from four to seven in a litter, and hence it is that a small number at first will soon stock a whole warren, if left to breed a little while undisturbed. The does cannot suckle their young till they have been at buck again; this therefore is to be done presently, else there is a fortnight lost of the time for the next brood, and the present brood also probably lost. When the buck goes to the doe, he always first beats and stamps very hard with his feet, and when he has copulated with her he falls backwards, and lies as it were in a trance; in this state it is easy to take him, but he soon recovers from it.

The buck *rabbits*, like our boar cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their stocks, or nests, with gravel or earth, which they close so artificially up with the hinder part of their bodies, that it is hard to find them out. They never suckle the young ones at any other time than early in the morning, and late at night, and always, for eight or ten days, close up the hole at the mouth of the nest, in this careful manner, when they go out. After this they begin to leave a small opening, which they encrease by degrees, till at length, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out; for they are at that time grown big enough to take care of themselves, and to feed on grass.

People who keep *rabbits* tame for profit, breed them in hutches, but these must be kept very neat and clean, else they will be always subject to diseases. Care must be taken also to keep the bucks and does apart till the latter have just kindled, then they are to be turned to the bucks again, and to remain with them till they shun and run from them.

The general direction for the chusing of tame *rabbits* is, to pick the largest and fairest, but the breeder should remember that the skins of the silver haired ones sell better than any other. The food of the tame *rabbits* may be colewort and cabbage leaves, carrots, parsneps, apple rinds, green corn, and vetches, in the time of the year; also vine leaves, grass, fruits, oats, and oatmeal, milk-thistles, sowthistles, and the like; but with these moist foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwise they will grow pot-bellied, and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff, and these may be given them three times a day; but when they eat green things, it must be observed that they are not to drink at all, for it would throw them into a dropsy. At all other times a very little drink serves their turn, but that must always be fresh. When any green herbs, or grass, are cut for their food, care must be taken that there is no hemlock among it, for though they will eat this greedily among other things, when offered to them, yet it is sudden poison to them.

Rabbits are subject to two principal infirmities. First, the rot, which is caused by the giving them too large a quantity of greens, or from the giving them fresh gathered with the dew or rain hanging in drops upon them. It is over moisture that always causes this disease, the greens therefore are always to be given dry, and a sufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moisture of their juices. On this account the very best food that can be given them, is the shortest and sweetest hay that can be got, of which one load will serve two hundred couples a year; and out of this stock of two hundred, two hundred may be eat in the family, two hundred sold to the markets, and a sufficient number kept in case of accidents.

The other general disease of these creatures is a sort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This distemper is supposed to be owing to the rankness of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called *tare-thistle*, to eat.

The general computation of males and females is, that one buck *rabbit* will serve for nine does; some allow ten to one buck; but those who go beyond this always suffer for it in their breed.

The wild *rabbits* are to be taken either by small cur dogs, or by spaniels bred up to the sport; and the places of hunting those who straggle from their burrows, is under close hedges, or bushes, or among corn-fields and fresh pastures. The owners use to course them with small greyhounds, and though they are seldom kill'd this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets, called *purse nets*, and ferrets. The ferret is sent into the hole to force them out, and the purse net being spread over the hole, takes them as they come out. The ferrets mouths must be muffled, and then the *rabbit* gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay net or two, at a small distance from the burrows that are intended to be hunted: thus very few of the number that are attempted will escape. The method by the dog, called the *lurcher* and *tumbler*, is also a very good one. See FERRET and LURCHER.

Some who have not ferrets smoak the *rabbits* out of their holes with burning brimstone and orpiment. This certainly brings them out into the nets, but then it is a very troublesome and offensive method, and is very detrimental to the place, as no *rabbit* will, of a long time, afterwards come near the burrows which have been fumed with these stinking ingredients.

The testicle of a *rabbit* is a very good object for examining the structure of this part of generation in animals. The whole substance of the testicle in this animal is made up of vessels, which lie in round folds in the manner of the smaller intestines, but then both ends of each roll meet at their insertion, which seems to be made into the *ductus nervosus*; and every one of these little rolls is curiously embroidered with other vessels, which, from their red colour, appear to be arteries and veins. The several little rolls lie in ranges, disposed with an uniformity which is very agreeable to the eye. Every one of these rolls is not a single and entire tube, but each consists of several tubes, beside the veins and arteries which embroider it. This is best distinguished by the cutting one of the rolls transversly, and then examining the cut end with a glass, which will then appear to be made up of the cut and open ends of four, five, or more parallel tubes, which together form the roll, or single tube, as it appears to the eye, being all wrapped up in one common and very thin membrane. These are so tender that they cannot be explicated and viewed distinct, as De Graeff tells us those of the testicles of a rat, and of some other animals, may. These however, as well as the others, are only made up of a congeries of vessels, and the liquors, which are their contents, without any intermediate substance, or any thing of that parenchyma, which many authors have talked of. The testicles of a bull have the greatest appearance of a fleshy texture of those of any known animal, yet even these afford no particle of parenchyma, or flesh, when examined by glasses in any sort of preparation, whether boiled, raw, soaked in spirits, or in whatever other state. The testicles of various animals are very variously composed, but all in this general manner of vessels variously rolled and folded together; and even the human testicles are of the same sort, being composed solely of rolls of vessels, without any intermediate substance, be it called by whatever name, but only consisting of vessels and their liquors. Philos. Trans. Nº 52.

RABCHORCADO, in zoology, the name of an American bird, described by Nieremberg with many fabulous circumstances. All that seems certainly known is, that its tail is very remarkably forked. *Ray's* Ornithol. p. 305.

RABEBOIA, a name given by some to the roots of the flammula major.

RABICH, a name given by Leo Africanus to a tree or shrub growing very plentifully in many parts of Africa, the fruit of which is much esteemed by the natives. He says that the tree *rabich* is prickly, and that the fruit is round and like a cherry, but smaller, and of the taste of the jujube. *Leo Africanus*, lib. 3.

RABIEL, a name given by some authors to dragons blood. See SANGUIS *draconis*.

RABIRA, a word uſed by ſome of the chemical writers to expreſs tin. See TIN.

RABOLANE, in zoology, a name given by many to the lagopus, a bird found on the ſnowy mountains, and called by ſome the *white partridge*. *Ray*'s Ornitholog. p. 127. See the article LAGOPUS.

RABRI, a name given by ſome authors to bole armenic.

RACE, in natural hiſtory. See CIBDELOPLACIA.

RACHISAGRA, a term uſed by ſome phyſicians for the gout in the ſpine of the back.

RACING, the riding heats for a plate or other premium.

The firſt thing to be conſidered in this ſort of gaming is the chuſing a rider; for it is not only neceſſary that he ſhould be very expert and able, but he muſt alſo be very honeſt.

He muſt have a very cloſe ſeat, his knees being turned cloſe to the ſaddle ſkirts, and held firmly there, and the toes turned inwards, ſo that the ſpurs may be turned outward to the horſe's belly. His left hand governing the horſe's mouth, and his right the whip. During the whole time of the *race* he muſt take care to ſit firm in the ſaddle, without waving or ſtanding up in the ſtirrups. Some jockies fancy this is a becoming ſeat; but, it is certain, that all motions of this kind, do really incommode the horſe. In ſpurring the horſe, it is not to be done by ſticking the calves of the legs cloſe to the horſe's ſides, as if it were intended to preſs the wind out of his body; but, on the contrary, the toes are to be turned a little outwards; that the heels being brought in, the ſpurs may juſt be brought to touch the ſides. A ſharp touch of this kind will be of more ſervice toward the quickening a horſe's pace, and will ſooner draw blood than one of the common coarſe kicks. The expert jockey will never ſpur his horſe until there is great occaſion, and then he will avoid ſtriking him under the fore bowels between the ſhoulders and girth; this is the tendereſt part of a horſe, and a touch there is to be reſerved for the greateſt extremity.

As to whipping the horſe, it ought always to be done over the ſhoulder on the near ſide, except in very hard running, and on the point of victory; then the horſe is to be ſtruck on the flank with a ſtrong jerk; for the ſkin is moſt tender of all there, and moſt ſenſible of the laſh.

When a horſe is whipped and ſpurred, and is at the top of his ſpeed; if he claps his ears in his pole, or whiſks his tail, it is a proof that the jockey heats him hard, and then he ought to give him as much comfort as he can, by ſawing the ſnaffle backwards and forwards in his mouth; and by that means forcing him to open his mouth, which will give him wind, and be of great ſervice. If there be any high wind ſtirring in the time of riding; the artful jockey will let his adverſary lead, holding hard behind him, till he ſees an opportunity of giving a looſe; yet, in this caſe, he muſt keep ſo cloſe behind, that the other horſe may keep the wind from him; and that he ſitting low, may at once ſhelter himſelf under him, and aſſiſt the ſtrength of the horſe.

If the wind happen to be in their back a juſt contrary method is to be taken with it; the expert jocky is to keep directly behind the adverſary, that he may have all the advantage of the wind to blow his horſe along, as it were, and at the ſame time intercept it in regard to his adverſary.

When running on level carpet ground, the jockey is to bear his horſe as much as the adverſary will give him leave, becauſe the horſe is naturally more inclined to ſpend himſelf on this ground: on the contrary, on deep earths, he may have more liberty, as he will there ſpare himſelf.

In riding up hill the horſe is always to be favoured, by bearing him hard, for fear of running him out of wind; but, in running down hill, if the horſe's feet and ſhoulders will bear it, and the rider dares venture his neck, he may have a full looſe. If the horſe have the heels of the reſt, the jockey muſt always ſpare him a little, that he may have a reſerve of ſtrength, to make a puſh at the laſt poſt.

A great deal depends on the jockey's knowing the nature of the horſe that is to run againſt him, for by managing accordingly, great advantages are to be obtained: thus, if the oppoſite horſe is of a hot and fiery diſpoſition, the jockey is either to run juſt behind him, or check by joul with him, making a noiſe with the whip, and by that means forcing him on faſter than his rider would have him, and conſequently ſpending him ſo much the ſooner: or elſe keep juſt before him, in ſuch a ſlow gallop, that he may either overreach, or by treading on the heels of the fore horſe, endanger tumbling over.

Whatever be the ground that the adverſary's horſe runs worſt on, the cunning jockey is to ride the moſt violently over; that by this means, it will often happen, that in following, he either ſtumbles or claps on the back ſinews.

The ſeveral corrections of the hand, the whip, and the ſpur, are alſo to be obſerved in the adverſary, and in what manner he makes uſe of them; and when it is perceived, by any of the ſymptoms, of holding down the ears, or whiſking the tail, or ſtretching out the noſe like a pig, that the horſe is almoſt blown; the buſineſs is to keep him on to this ſpeed, and he will be ſoon thrown out or diſtanced.

If the horſe of the opponent looks dull, it is a ſign his ſtrength fails him; and if his flanks beat much, it is a ſign that his wind begins to fail him, and his ſtrength will ſoon do ſo too.

After every heat for a plate, there muſt be dry ſtraw, and dry cloths, both linnen and woollen, ready to rub him down all over, after taking off the ſweat with what is called a ſweat knife; that is, a piece of an old ſword blade, or ſome ſuch thing. Some adviſe the ſteeping the cloths in urine and ſalt-petre the day before, and letting them be dried in the ſun for this occaſion. After the horſe has been well rubbed with theſe, he ſhould be chafed all over, with cloaths wetted in common water till the time of ſtarting again. When it is certainly known that the horſe is good at the bottom, and will ſtick at the mark, he ſhould be rid every heat to the beſt of his performance; and the jockey is, as much as poſſible, to avoid riding at any particular horſe, or ſtaying for any, but to ride out the whole heat with the beſt ſpeed he can. If, on the contrary, he has a fiery horſe to ride, and one that is hard to manage, hard mouthed, and difficult to be held, he is to be ſtarted behind the reſt of the horſes with all imaginable coolneſs and gentleneſs; and when he begins to ride at ſome command, then the jockey is to put up to the other horſes; and if they ride at their eaſe, and are hard held, they are to be drawn on faſter; and if it be perceived, that their wind begins to rake hot, and they want a ſob, the buſineſs is to keep them up to that ſpeed: and when they all are come within three quarters of a mile of the poſt, then is the time to puſh for it, and uſe the utmoſt ſpeed in the creature's power.

When the race is over, the horſe is immediately to be cloathed up, and rode home, and immediately on his coming into the ſtable the following drink is to be given him. Beat up the yolks of three eggs, and put them into a pint and half of new milk made warm; let there be added to this three pennyworth of ſaffron, and three ſpoonfuls of ſallad oil, and let the whole be given with a horn. After this he is to be rubbed well down, and the ſaddle place rubbed over with warm ſack, and the places where the ſpurs have touched, with a mixture of urine and ſalt, and afterwards with a mixture of powder of jet and Venice turpentine; after this he ſhould have a feed of rye bread, then a good maſh, and at ſome time after theſe as much hay and oats as he will eat. His legs after this ſhould be bathed ſometimes with a mixture of urine and ſalt-petre.

RACK (*Cycl.*)—RACK, or *Arrack*, is properly a ſpirit procured by diſtillation, from the fermented juice of certain trees in the Eaſt Indies. See ARAC, *Cycl.*

Various and contradictory accounts have been delivered, as to the real ſubject that gives origin to this fine ſpirit. The vulgar ſuppoſe it to be rice; ſome the juice of the Eaſt Indian ſugar canes; and others a mixture of the juice of this cane and of the toddy tree; finally, ſome affirm, that it is prepared from the fleſh of animals, and other more coſtly ingredients.

The juice of the cocoa trees, and palm trees, are what afford us the fineſt *arracks*; but there are many other juices diſtilled into the ſame kind of liquors, though wanting the fine flavour of what is made from theſe. *Shaw*'s Eſſay on Diſtillery.

The manner of making the *arrack* is this. The juice of the trees is not procured in the way of tapping the trees, as we do; but the operator provides himſelf with a parcel of earthen pots, with bellies and necks, like our ordinary bird bottles; he makes faſt a parcel of theſe to his girdle, and any way elſe, that he commodiouſly can about him. Thus equipped, he ſwarms up the trunk of a cocoa tree; and when he comes to the boughs, he takes out his knife, and cutting off one of the ſmall knots, or buttons, he applies the mouth of the bottle to the wound, faſtening it to the bough with a bandage; in the ſame manner he cuts off other buttons, and faſtens on his pots, till the whole number is uſed; this is done in the evening, and deſcending from the tree, he leaves things to themſelves till the next morning, when climbing up again he takes off the bottles which are moſtly filled, and empties the juice into the proper receptacle. This is repeated every night, till there is a ſufficient quantity produced, and the whole being then put together, is left to ferment, which it ſoon does.

When the fermentation is over, and the liquor, or waſh, is grown a little tart, it is put into the ſtill, and a fire being made, the ſtill is ſuffered to work, as long as what comes over has any conſiderable taſte of ſpirit.

The liquor thus procured is the low wine of *arrack*, and this is ſo poor a liquor, that it will ſoon corrupt and ſpoil, if not diſtilled again, to ſeparate ſome of its phlegm; they therefore immediately after pour back this low wine into the ſtill, and rectify it to that very weak kind of proof ſpirit, in which ſtate we find it. The *arrack* we meet with, notwithſtanding its being of a proof teſt, according to the way of judging by the crown of bubbles; holds but a ſixth, and ſometimes but an eighth part of alcohol, or pure ſpirit; whereas our other ſpirits, when they ſhew that proof, are generally eſteemed to hold one half pure ſpirit. Ibid.

This ſhews how very uncertain a way of judging of the ſtrength of ſpirits, this by the bead or bubble proof is. And we

we may from this learn, that it would be much better to have the *arrack* rectified to the pure alcohol in the Eaft Indies, in which cafe it would be brought over in one fixth, or one eighth part of the room, and might be lowered to its ftandard with common water here. All that it contains befide this fixth or eighth part of fpirit, being only a poor phlegm, or an acidulated water, valuable only for having been brought from Goa or Batavia. It may appear ftrange to fome, that this fpirit fhould be proof, according to the way of judging by the bead or bubble, and yet be fo far below the ftrength, which we ufually underftand to be in proof fpirit. But the truth is, that this ftanding crown of bubbles, may be owing only to the tenacity of the oil that is held in the fpirit. Our malt diftillers know very well, that the more oil they work over with the fpirit, the ftronger proof it will hold, at a fomewhat weaker ftandard of ftrength than it ought to have, and this cafe of the *arrack* fhews the fallacy of the other. The finer and more fubtile any oil is, the lefs it refufes to mix with any aqueous menftruum: thus we fee that the effential oils of fome vegetables, or at leaft fome portion of them, is fo fine and fubtile, as to mix without turning milky, even with water itfelf, which is the cafe in many of our fimple diftilled waters. Hence, it is no wonder, that fo fubtile an oil, as is contained in that thin and dilute vegetable juice of which *arrack* is made, fhould readily mix with fuch a mixture, as that of one part alcohol, and fix or eight of water, which tho' weak, confidered as a fpirit, is much more likely to retain and embody an oil, than fimple water alone. The oil of the cocoa is thus fufpended imperceptibly in the fpirit; and that in fuch quantity, as to give a tenacity to the whole, that difpofes it to form a froth or lather at the top when fhook, and the bubbles of that froth to hang well together. Sometimes indeed there come over into England, and more frequently into Holland, *arracks* that are of the ftrength of brandy and rum: thefe chiefly come from the Dutch fettlements, and are a piece of frugality of the Dutch to fave freight: it is a wonder the faving fpirit had not gone a little farther, and the method of reducing *rack* to alcohol been found out on the fame plan.

Befide the common forts of Goa and Batavia *arrack*, there are two others lefs generally known; thefe are the bitter *arrack* and the black *arrack*. The bitter *arrack* is fuppofed to have been impregnated with fome kind of bezoar, as that of the porcupine or monkey, which being not generated in the ftomachs, as thofe of other animals, but in the gall bladder, are of a very ftrongly bitter tafte, and very readily communicate it to other things.

Some, on the contrary, are of opinion, that there is nothing added to this, but that the tafte is owing to the juice of the trees, from which the *arrack* is made; and many think that it is obtained from the juice of that tree which bears the fruit, whofe infpiffated juice is what we call terra Japonica.

The black *arrack* is a very coarfe fpirit, and is ufually drawn higher than any of the finer kinds are, being not drank like them, but employed for coarfer purpofes. The Turkifh *arrack*, or as it is ufually called *rackee*, feems to be of this kind. The finer, and better kinds of *arrack*, though ever fo good, when put on board, are apt to grow foul, and black in the carriage; if the leager, or cafk, in which they are brought over, be decayed on the infide, or the liquor come to touch any nails, or rufty iron of any kind; for the fpirit prefently diffolves a part of the ferrugineous matter; and thence, upon account of the tincture of the oak, which it had before obtained from the wood of the cafk, it will appear inky. *Arrack*, that is thus accidentally tinged black, is not to be confounded with fuch *arrack* as is originally black, and of the coarfe kind named before. This, which has obtained the colour by accident, is not the worfe in tafte for it, and the tinge may be taken off, and the liquor recovered by putting into the cafk a large quantity of new or fkimmed milk; and working it well about, as the vintners do, in order to whiten their brown wines. When the bottoms are large, they are to be committed to a conical filter of flannel, through which the *arrack* runs fine. This art of purifying foul *arracks* with milk, would be very pardonable, if our dealers only impofed that upon us: but they have a fhameful way of lowering this fpirit with water, and that to fuch a degree as is fcarce credible.

The weaknefs of fome genuine *arracks* greatly contributes to the countenancing this cheat. This is the principal deceit ufed in regard to this commodity; for it is not eafy to find any other fpirit taftelefs enough to mix with it, without difcovering the cheat with us; and in Holland they are not only more deftitute of clean fpirits than here, but the price of *arrack* itfelf is fo low there, that it is hardly worth while to do it if they had proper materials.

The extravagant price that *arrack* bears in England, has given great occafion to the diftillers to endeavour the counterfeiting it. All the attempts which, for cheapnefs fake, have been made with malt fpirit, have naturally proved unfuccefsful: but the thing is not impracticable, though thefe methods have failed. The firft requifite muft be the making a perfectly taftelefs fpirit, and the next the treating the juices of vegetables, fo as to obtain their flavour, to add to it, or elfe the obtaining a pulverable dry fubftance, which would at once mix with the fpirit, and prevent the trouble of a fecond procefs of diftillation. It is poffible, alfo, that the Englifh juices of trees, which will bleed freely, fuch as the birch, maple, fycamore, and the like, may, on proper trials, be found to afford this fort of fpirit in fome degree of perfection.

RACKOON, in zoology, the name by which we commonly know an American animal, called *coati* by the Brafilians. It is fomething fmaller than the beaver, and is of the fhape of the beaver in its body, and its legs are as fhort as in that creature. Its hair is like that of a fox, very long, foft, and placed thick together, and black at the ends, and brown toward the body. Sometimes from this mixture of colour the back appears plainly grey; and Marggrave mentions another fpecies, which is of a deep yellow or ochre colour. *Ray's* Syn. Quad. p. 179.

The head is very like that of the fox in fhape; but that the ears are fhorter, roundifh, and naked, and therefore has a black line drawn acrofs the eyes. The eyes are large, the nofe is black, and rounded at the extremity, like that of a dog; its tail is longer than its body, and is very like that of a cat, having annular marks of different colours. Its feet are each divided into five flender toes; by the help of which it climbs trees as expertly as a monkey, and ufes the fore feet as hands, to reach up its food to its mouth. It is a very cleanly animal; and if there be water any way near, it always wafhes its food, be it what it will, before it eats it. It feeds on vegetables, but is alfo very fond of eggs, and will even feize birds if it can catch them. It is very common in many parts of the Weft Indies, and is a creature eafily tamed.

RADAINUS, among the writers of the middle ages, the name of a black ftone fomewhat tranfparent, and faid to be found in the head of a cock; and, by others, in the head of a fea fifh. They fay the method of finding the ftone was to put the creature's head into an ant-hill, where thefe infects having eaten away the flefh, the ftone was eafily found among the bones.

RADIALIS (*Cycl.*)—Radialis *externus primus & fecundus*, two mufcles clofely united together; appearing, at firft fight, like one mufcle, lying along the external angle of the radius, between the os humeri and the carpus, being flefhy near the former, and tendinous near the latter.

In many fubjects we find thefe two mufcles entirely diftinct from one end to the other; and they may, in that ftate, be named *radialis externus primus*, and *radialis externus fecundus*, regard being had to the infertion of their tendons. Sometimes the two flefhy portions adhere clofely together, appearing to make but one body, but the tendons are always diftinct and feparate. The firft is inferted above in the crifta of the external condyle of the os humeri, below the infertion of the fupinator longus. The fecond is inferted in the fame condyle below the infertion of the firft, and in the neighbouring articular ligament. From thence the two flefhy bodies run down very clofe together, and having reached the middle of the outfide of the radius, each of them terminates in a long tendon.

The two tendons accompany each other to the extremity of the radius, and having paffed under a particular annular ligament; they are divided as it were into two cornua, from whence the antients, who looked upon them as but one mufcle, called it bicornis. One of thefe tendons is inferted anteriorly in the bafis of the firft metacarpal bone, the other nearly in the fame part of the fecond bone, and the tendon of the firft is fometimes double, appearing like another bicornis. *Winflow's* Anatomy, p. 193.

Radialis *internus*, a long mufcle, very like in fhape to the ulnaris externus, but fituated more obliquely. Its flefhy portion is fixed by a fhort tendon to the outer and upper fide of the inner condyle of the os humeri, from thence it paffes obliquely toward the radius, and running along about two thirds of that bone, it forms a long tendon, which continues in the fame courfe; and at the lower extremity of the radius, paffes under a particular annular ligament, and under the infertion of the mufculus thenar. This tendon is at length inferted chiefly in the infide of the bafis of the firft metacarpal bone, and alfo often in the fecond, and a little in the firft phalanx of the thumb; having firft paffed through the channel of the os trapezium which fuftains the thumb. *Winflow's* Anatomy, p. 191.

RADIATED *flowers*, (*Cycl.*) in botany, a term ufed by Mr. Tournefort, and others, to exprefs flowers, like that of the great daify, fun flower, &c.

A *radiated* flower has two parts; its middle part which is called the difk, and which is wholly made up of flofcules; and the outer part, which is called the circle or border, which is wholly made up of femi-flofcules, or elfe of plain flat leaves; but that is lefs common. The flofcules and femi flofcules both ufually adhere to the embryos, and to the thalamus of the flower, being contained in one general cup. Thefe embryos finally ripen into feeds; fometimes furnifhed with down, fometimes with foliaceous heads, and fometimes without either, and fometimes marginated. Of thefe feeds fome are wrapped round with a kind of cafe or capfule, others are feparated from one

one another by small perpendicular leaves. See Tab. 1. of Botany, Class 1. *Tourn.* Inst. p. 480.

RADIATED *leaf*, among botanists. See LEAF.

RADICAL (*Cycl.*)—RADICAL *numbers*, *numeri radicales*, in the Italian music, are 2, 3, 4, 5, 6, 7, 8, 9, and sometimes 10, which are often met with in musical compositions, to denote the accords of the thorough basses. 2 stands for the second and its duplicates; 3 for the third; 4 for the fourth, &c.

RADICAL *leaf*, among botanists. See LEAF.

RADICATUM *folium*, among botanists. See LEAF.

RADII (*Cycl.*)—RADII *pinnarum*, in ichthyology, the little slender bones supporting the membrane, forming the fins in fishes, and called by Artedi *officula radiata pinnarum*, from their running from the base to the summit in the form of rays. See FIN.

Of these *radii* some are prickly, others not. The prickly ones are always hard and rigid, the others are always soft and flexile, whether they terminate single, or are split into two or more branches at the extremity. The prickly ones are always formed of single bones; the others always of two bones, each applied closely and evenly to one another. When the fish is alive, it is not always easy to separate these, but when it is boiled, they are easily parted at the base, and sometimes all the way up. The fish, which have the single and prickly fins on their back, belly, or at the anus, are these: the percæ, the spari, the labri, the amiæ, the trachuri, the mugiles, the sudes, the trachini, the zei, the mulli, the ligyri, the gasterostei, the scorpœnæ, the caprisci; in these the *radii* are all single, and are more or less prickly. In the mackrel, the *radii* of the first fin of the back, and those of the belly fins, are absolutely simple, but they are scarce observably prickly.

The following genera of fishes are those which have the *radii* of the fins all double at the base, and soft and flexile: the syngnathi, the cobitides, the cyprini, the clupeæ, the coregoni, the osmari, the esoces, the pleuronecti, the gadi, and the congers. The softer and the more flexile these bones are, the more numerous, transverse, and lucid internodia they have in them. The cyprini give us many instances of this, as also the clupeæ, the coregones, and the esoces. Those which have fewer of these internodia, or transverse lines, are somewhat more rigid, though not aculeate, or prickly: this we see in the pleuronecti and gadi. Beside these *radii*, there are certain other small bones which are of an oblong figure, and serve to sustain the bases of the back fins, and the fin at the anus. The back fins, and those at the anus, are not joined by their rays to some one large muscle, or large bone, as the pectoral and ventral fins are; but every *radius*, or bone in these fins, is affixed to an oblong bone, erected perpendicularly between the apophyses of the vertebra and the back of the fin. The rays are joined at their base to these bones by an articulation, and fastened in by means of a cartilage; and these bones do not adhere to the apophyses of the vertebra, but are placed regularly between them. These bones are always single, and in many kinds of fish, as in the pleuronecti, they are hollow at the bottom. Between these bones, and the first rays of the back fin, in mackrel, there are found certain other little bones, placed semicircularly and transversely, but their apices are striated, and turn a little upwards. This is an observation yet made only in a few fish, but it is worth while to examine whether it is found in those other fish also, which have sulci at the back fins. *Artedi*'s Ichthyolog.

RADISH, *raphanus*, in botany. See RAPHANUS.

There are several varieties of the root of the common garden *radish*, which is the only species cultivated by our gardeners: these are called by them the small top'd *radish*, the deep red, and the striped *radish*, &c. All these are only varieties arising from the culture. The small topped is the kind, the seed of which is most saved, and which is most valued about London, because it does not take up much room. They are sown at various seasons, but the earliest is generally at the latter end of October; if these are not destroyed by frosts, they become fit to eat in March. These are commonly sowed about walls, pales, or hedges, where they may have some defence against the cold. The second sowing is commonly about Christmas, if the weather be mild enough to let the ground be worked. These are also to be sown under a shelter, and, if they are not destroyed, will be fit to eat in April; and to have a constant supply, there should be a new sowing every fortnight, from the middle of January to the beginning of April. The later crops should be sown on a moist soil, and in an open situation. *Miller*'s Gard. Dict.

RADIUS (*Cycl.*)—RADIUS *of curvature*, or *Radius of the curvature of a curve*, is the *radius* of a circle that has the same curvature in a given point of the curve, that the curve has in that point.

RADIUS, among the Romans, a name given to the iron rod with which the boys rolled the trochus. See the article TROCHUS.

RADIUS, in anatomy. The *radius* is nearly of the same length with the ulna, bigger at one end than at the other, irregularly triangular, a little bent, and situated sideways along the ulna, and has its name from the resemblance it bears to the *radius*, or spoke of a wheel. Anatomists describe in this bone a middle portion, and two extremities. One extremity is small, and like a kind of head set upon a neck; the other is large, resembling a pedestal, or basis; and the bone might therefore be very properly divided into the head, body, and basis.

The head, or small extremity of the *radius*, is very short or low, the top of it is concave, and the circumference cylindrical, and both the glenoide cavity, and whole circumference, are covered with the same smooth shining cartilaginous crust, and about one quarter of the circumference is broader than the rest. The neck is small, and its situation a little oblique; it ends by a lateral tuberosity, which lies directly under the broad part of the head, being rough in the middle, and on one side, and smooth and superficially cartilaginous on the other.

The basis, or great extremity of the *radius*, is much broader than it is thick, and has two broad sides, and one narrow one. One of the broad sides is a little hollow, and pretty even; the other is unequally convex, and divided by longitudinal eminences, or bony lines, into three or four longitudinal channels; but these are much more distinct in fresh bones, than in the dried sceleton. The narrow side is hollowed lengthwise, and between it, and the other two, are formed two angles, by which the three sides are distinguished; and opposite to it, the other two meet in a third angle. This narrow side ends in a semilunar cavity, bordered by a smooth cartilage, and lying almost in the same direction with the tuberosity. The broad sides end at their common angle by an obtuse point, or production, which has been called the *styloide apophysis* of the *radius*, and is in reality a continuation of one of the bony lines already mentioned. The whole basis ends in an oblong, triangular glenoide cavity, the cartilage of which is continued over the hollow edge of the narrow side. This is an articular cavity, resembling an arch, and ending on one side at the styloide apophysis, and hollowed on the other by the cavity of the narrow side. It appears divided into two portions by a small transverse line, and in the natural state, the hollowed side is lengthened out by a cartilaginous production, which is lost in the dried sceleton.

The middle, or body of the *radius*, is a little incurvated, the concavity lying between the tuberosity in the head, and the semilunar cavity in the basis. It has three sides; one rounded, which is the convex side of the curvature, and two concave; three angles, two of which are obtuse, distinguishing the two concave sides from the convex, and the third acute, lying between the concave sides, opposite to the convex side. In each of these sides there are several muscular impressions. The head and basis of this bone are epiphyses in children, and in some subjects remain such for a long time afterwards. The *radius* is connected with the ulna, os humeri, and carpus. It is articulated with the ulna, at its two extremities, by a double lateral ginglymus, the cartilaginous substance of the head turning in the small sigmoide cavity, and the semilunar cavity in the basis turning upon the small head at the lower extremity of the other bone, and thus the small extremity of one of these bones is joined to the great extremity of the other. It is articulated with the os humeri by the application of the cavity in the top of its head to the small head at the lower extremity of the other bone: by this conformation it would be capable of moving in all directions; but as it is tied to the ulna at both extremities, its motions on the small condyloide head, at the lower extremity of the os humeri, are confined to two kinds; that of rotation, when it turns on the sides of the extremities of the ulna; and that of flexion and extension in common with the ulna; and both these motions may be performed at the same time. *Winslow*'s Anatomy, p. 80.

Cartilages of the RADIUS. At the basis of this bone there is a particular cartilage, or triangular production, very thin, longer than it is broad, and rather flat than concave. It is fixed by the basis, or shortest side, to the lateral sigmoide notch of the basis of the *radius*; the other side touches the flat extremity of the small head of the ulna, but is not affixed to it. This may properly enough be called the inter-articular cartilage of the wrist. It is tied to the *radius* by very short ligaments, and sliding on the small head of the ulna, it follows all the motions of the *radius*. It is therefore a sort of articular production of the lower side of the basis of the *radius*, and in the natural state fills the void space which, in the sceleton, appears between the end of the ulna and neighbouring bone of the carpus. *Winslow*'s Anatomy, p. 140.

Ligaments of the RADIUS. Many of the ligaments of the bones of the fore arm are common to them, and to the os humeri, and others to them, and the bones of the head: two however there are which are proper to this part of the arm, the one called the interosseous ligament of the fore arm, the other the coronary ligament of the *radius*; and

and to these may be added the annular ligaments, which serve only for the passage of tendons, and other ligamentary expansions, which may be called muscular ligaments. The interosseous ligament of the fore arm is like that of the leg; it is fixed by one edge along the sharp angle of the *radius*, the other along that of the ulna. It is principally made up of two very strong planes of fibres, which cross each other at oblique angles, and leave holes at different distances for the passage of blood vessels. This ligament ties the two bones closely together, and the two planes serve for the insertion of several muscles. The coronary ligament of the *radius* is a sort of ligamentary hoop, surrounding the circular circumference of the head of that bone. It is very strong, and comes near the solidity of a cartilage, and the side next the *radius* is very smooth. The capsular ligament of the joint of the elbow runs down from its insertion in the os humeri, and is fixed in the olecranum, round the edge of the great sigmoide cavity, including both the apex of the olecranum, and of the coronoide apophysis.

The true common ligaments, by which the os humeri is connected to the bones of the fore arm, called lateral ligaments, are the two fasciculi, which, after being inserted in the condyles of the os humeri, are expanded like a goose's foot; that which is fixed in the inner condyle is called the brachio-cubital, the other the brachio-radical.

Of the ligaments by which the bones of the fore arm are connected to those of the hand, one is like a roundish cord fixed in the styloide apophysis of the ulna, and from thence passes over the os cuneiforme of the carpus; and another pretty broad ligament is fixed on the point of the *radius*, and by its other extremity in the bones of the carpus. From this styloide ligament of the *radius*, along each edge of the basis of that bone, are ranks of ligamentary fibres, lying much in the same direction with the ligament itself, and continued all the way to the styloide ligament of the ulna. There are also several small annular ligaments placed at different distances on the convex side of the basis *radii*, from its styloide apex to its articulation with the extremity of the ulna; these are at least six in number, and some of them are double or triple. The first of these is fixed in the styloide apex; the second in the groove near that apex; the third in the small, narrow, or middle groove; the fourth in the groove next the former; the fifth in the corner of the notch of the basis, at its articulation with the ulna; and the sixth in the extremity of the ulna, near the styloide apophysis. These are all almost wholly covered by the great oblique ligament, and are fixed as strongly in it on one side, as they are in the bones on the other. *Winslow*'s Anatomy, p. 141. seq.

RADIUS *articulatus*, in natural history, a name given by Mellius, Gmelin, and some other authors, to a kind of figured fossils, of which there are a great many very different species, some of which have been described by authors among the belemnitæ, under the names of *alveoli belemnitarum*. Mr. Gmelin, who has taken great pains to inform himself, as well of the nature and figure of these stones, from the subjects themselves, as of their history, and the various accounts of them from other authors, observes, that the place where they are most frequent is Sweden, and that there they are no where so common as in the isle of Oeland. Volkman figures some also which he found in Silesia, and Helwing others which he collected in Prussia: he also found great numbers of them himself in Russia.

They are usually immersed in lime stone, and though at first sight they may all appear alike, yet, on a careful examination, they will be found to differ very greatly. The most obvious general distinction, established by Mr. Gmelin, is, that some of them are strait, and others crooked.

The strait ones may be divided into two genera. The first of these comprehends, according to this gentleman, two species: the first smooth, and with a converging alveolus. This consists of several patellæ of a roundish figure, and disposed in a parallel manner over one another. Each of these patellæ is convex on one side, and concave on the other; and the convex part of one is in the articulation, which joins them into one body, always received into the concave part of another, whose convex part is again received into the concave of a third, and so on throughout the whole body. The diameter of the largest of this species is about two inches, and that of the least an inch. The circumference is not perfectly circular, but in one part is cut in manner of a crescent. This hollow is made for the reception of another cylindric stone, which is not articulated, and which Mr. Gmelin calls an *alveolus*. This alveolus runs through all these crescents in a strait and continued course, and standing out beyond the patellæ, of which the body is composed, is surrounded with a series of fasciæ, more or less elate: these answer to so many of the patellæ, and from these indeed it seems to have obtained this figure; but when this alveolus has, by any accident, been disengaged from its *radius*, it is easily rendered smooth by attrition and other accidents, and is usually found smooth when loose. Acta Petropol. Vol. 3. p. 248.

These are general characters, and are observed in all the specimens of this species; but there are other accidental varieties found in the different ones. Some have the patellæ and the alveolus standing out beyond them, all covered with a thin crust of a matter plainly testaceous, and in some the shelly matter is also found between the junctures of the patellæ. Sometimes also there are seen, at every junction of the patellæ, certain little forked bodies, standing upon the outer part of the alveolus, and seeming to join the several patellæ together. Sometimes the *radii* are found without the alveolus, but then there is always a cavity, or the remains of a cavity, in form of a canal, answering to every lineament of the alveolus; and this is ever covered with a shelly crust on its inner surface. Many of these *radii* are found remarkably compressed, bent, or distorted, which is an accident accounted peculiar to the fossils formed in animal moulds, and shews, with the shelly matter, that the whole must be the remains of some sea fish. Often also, when the whole substance is not injured in its form, the alveolus alone is oddly bent and distorted, whence it appears that it was originally of a tenderer texture than the rest, and there are also evident marks of its having been once hollow.

These are the characters and varieties of this species of *radius*, and there do not seem to be any distinct species under this, unless we are to account for such, those in which the patellæ are a little thicker, or a little thinner, or where they stand closer, or farther asunder. They are found from twelve to eighteen inches in length, but never seem to have been found with the posterior extremity perfect. They all lose themselves in the stone, keeping through their whole extent, as far as they can be traced, the same cylindric figure, without tapering toward either end. It is true, that in some of the stones where they are immersed, and which are polished for various uses, they often seem to grow gradually smaller, so as to terminate in a point; but this may be owing to their being cut in a slanting, not a truly horizontal position, and the bodies themselves may be truly cylindric all the while. Possibly, however, there may be of these, as of the belemnitæ, some cylindric, and others conic; or perhaps all may be conic, but that we have not been able perfectly to trace them.

The second species of the first genus, is the strait articulated *radius* which contains an alveolus, and is of a striated texture. This is composed of patellæ, which stand close, and are firmly joined together. These are convex on one side, and concave on the other, and their several diameters sensibly decrease toward one end. These contain also an alveolus. The patellæ, of which this species is composed, are of an elliptic figure, and each is surrounded with numbers of circular striæ. Ibid. p. 256.

The second genus of the *radii* comprehends those which are strait, and which have a siphunculus running all the way through their middle. These are composed of patellæ of equal diameters, laid parallel on one another, and are convex on one side, and concave on the other; and by this shape are adapted mutually to receive, and be received by one another. The siphunculus in these may often be traced very fairly, and seen to have been once hollow, though in this fossile state it is filled up with the matter of the stone in which the body is lodged; but sometimes they are almost obliterated, either in the whole length of the *radius*, or in one part or other of it. Another species of this is sometimes found, which seems only composed of circular rings, or segments of cylinders, not patellæ: this also has a siphunculus running its whole length, and both this, and the former, have often the remains of a thin coat of a shelly matter upon them.

These are the genera, and subordinate distinction of the first class of the articulated *radii*, that is the strait ones. The second class contains those which are crooked or twisted. The bodies of this class are much more rare than those of the former. They consist of patellæ, which are nearly round, only a little inclining to an elliptic figure; they are convex on one side, and concave on the other, and are each bored through with a small aperture, through which a siphunculus passes, running through the whole length of the body. Sometimes this is placed regularly in the middle, sometimes nearer to one side. There seem to be two species of this; the one composed of very thin patellæ, and the other of considerably thick ones.

The regular and nice configuration of these bodies, shews very plainly that they cannot be of mineral origin, but the several patellæ of which each is composed, the siphunculus of communication, obvious in several, and the shelly matter yet found remaining on many, prove them to have been once shell-fish of the univalve or tubular concamerated kind; the description of which, so far as it can be gathered from these remains, must have been this. The shell must have been either cylindric or conic in figure, of a smooth surface, and divided into several chambers or cells; but this so, that the septa which form the concamerations are not continued, and whole, but in some part of the periphery are cut in, in the shape of a crescent. Through these crescents, which standing

ftanding all together, make a continued canal, there has paffed another fhelly body of a cylindric or conic figure, alfo divided into concamerations; and that in fuch a manner, that the fepta which form the cells are pierced with a fmall aperture on one fide, which grows gradually fmaller as the fhell extends in length; and finally, through thefe apertures in the concamerations, there paffes another fhell pointed at the end, and like the reft divided into its concamerations, and pierced along its middle with a fiphunculus. Mem. Acad. Petrop. Vol. 3. p. 263.

This fhell is therefore a compages of three fhelly bodies, inclofed one within another; and it muft be fuppofed, in order to carry an analogy with other fhell-fifh, that thefe three fhelly bodies have communications with one another, by means of certain flits or perforations. The communication of thefe, one with another, feems alfo evident, from their being all found in their foffile ftate, filled with the fame ftony matter; this has, doubtlefs, been all received in at the fiphunculus of the inner fhell, and thence has been thrown into the fecond, and from this into the third fhell, fo as to fill up all the concamerations of the outer, as well as of the inner parts. This muft have been the cafe with thefe; and the feveral various fpecies that are at this day found foffile, muft have owed their origin to as many different fpecies of the fhells. The crooked, and twifted, or wreathed kinds, which have the fiphunculus, ufually placed near the fide, greatly approach in their ftructure to fome of the cornua ammonis.

RADIX (*Cycl.*)—RADIX *entrochorum*, the *root of the entrochi*, a name given by fome authors to a foffile fubftance, ufually found among the entrochi, and feeming to have been the bafis from which they have grown. It is plainly a part of the *ftella marina arborefcens* petrified, as thofe ftones alfo are: but people, who from a proper examination of the animal world, had miffed the true origin of thefe ftones, and called them rock plants, have efteemed this part of the fifh the bulbous root of the plant. This foffil is rarely found whole, but the fragments of it are very common. When entire, it is about the fize of a walnut; the top of it being flat, and in fome degree refembling the end of an entrochus, with a central hollow, but not having the leaft appearance of the rays of thofe ftones. Thefe foffils, though not properly judged of as to their origin, have yet been defcribed by a great number of authors. Agricola, in particular, compares the form of them to a wheel. The body of this kind well refembles indeed the nave of a wheel, the fhape of it being conical toward one end, till you come to the top, and then a little flatted, with a hole in it. There is alfo a like hole in the oppofite broad end of the fame foffil, feeming fit for an axle to pafs through; and there are five hollow ftirts, or feet, iffuing fideways, at equal diftances from the broad bottom, and equally carried on in the fame direction, fo as not amifs to reprefent the fpokes. At the end of each of thefe rays, or fpokes, there is a hollow, of the fame nature with thofe in the middle of the common entrochi, but this is cut acrofs by a feam, or ftreak of the fame ftone, which paffes directly over its center, and covers about a third part of it; this goes no farther than the mouth of the hole, but it cuts it into two, and fhews it in the form of two eyes. Thefe radii, or fpokes, are very feldom found fo perfect as here defcribed. Lifter mentions them as being formed like crefcents at the end, which may very eafily happen from the breaking off a part of the terminating part. Phil. Tranf. N° 129.

The *radix entrochorum* is never of a fmooth furface, but is wrought all over with trigonal, tetragonal, pentagonal, and hexagonal plates. The ufual ftructure is this: the upper part of the conical end is wrought round with fix large hexagonal plates. Thefe reach half way of the ftone, then follow a fecond round made up of eleven pentagonal plates; thefe are pretty large, and reach almoft to the broad bottom, which is a little convex. The bottom itfelf and the feet contain plates of all the fhapes, but they are ufually very fmall. The fubftance of this foffil is always a whitifh opake fpar, of the fame nature with the trochites. It has outwardly a rufty coat, and is blueifh within, like fmall fhells. It is generally found in clay, and is fo filled up with it, as to appear folid; but on the picking this out with a pointed inftrument, the whole appears to be only a hollow fhell, of about the thicknefs of a half crown piece.

The fmall fcales of pentangular and other figures, which make up thefe bodies, are often found loofe in the clay where the entrochi are alfo found; but they have fo little refemblance to any thing of the entrochus kind, that few have thought of referring them to that foffil, till they have met with the *radix* entire. There are a vaft variety of thefe plates, fome are convex, others concave; fome have edges plain and fmooth, others ferrated, and fome have, on the convex parts, the figure of a ftar, confifting of fix emboffed rays, with a ftud between every two of them, in the manner of the wires, or appendiculæ, growing from the afteriæ, which are a fort of foffils, evidently very nearly allied to the entrochus kind in all refpects.

RADIX *alba*, a word ufed by Diofcorides, to exprefs the root of the dracunculus.

RADULA, the *rafpatory*, a chirurgical inftrument ufed to cleanfe foul bones.

RAERS *of a cart*. See the article CART.

RAGS. In fome counties of England, particularly in Oxfordfhire, it is a common thing to ufe old woollen *rags* by way of manure upon land. Taylors fhreads anfwer this purpofe, in fome degree; but the old *rags* of cloaths, which have been worn by men and women, are much better, which is owing to the falts they have imbibed from the perfpiration of the body they ufed to cover. *Plot*'s Oxfordfhire, p. 250.

RAG-*bolts*, in a fhip, are fuch as have jags or barbs on each fide, to keep them from flying out of the hole wherein they are driven.

RAG-*ftone*, a name given by our artificers to a kind of ftone, which they ufe for fetting an edge upon knives, chifels, and other tools. It is a greyifh coloured ftone, containing a large quantity of talcky particles, and fplits eafily into thin flakes. It is a foft ftone, and is ufed only to finifh the fetting an inftrument after the edge has been prepared by grinding or rubbing the tool upon fome other ftone of a coarfer texture. We have this from Newcaftle and many other parts of the north of England, where there are very large rocks of it in the hills.

RAG-*wort*, *jacobæa*, in botany. See JACOBÆA.

There are two or three fpecies of this plant cultivated in the gardens of the curious; and one very common in moft places, which is the maritime kind, remarkable for its white leaves. This had been long ufed to be nurfed up, with great care, in our green houfes; but of late fome ftraggling feeds of it having propagated themfelves on a wall, and there ftood the winter's cold without hurt, we were taught that the plant did not require the care it had been ufed to be treated with.

All the kinds may be propagated by fowing their feeds in March, on a bed of light earth, watering it frequently in dry weather. In May the plants may be taken up, and planted in pots, and fet in a warm fituation till October, when the tenderer kinds are to be taken into a green-houfe. Thefe require much pruning in fummer to keep them in fhape, for they grow very faft, and in winter will die if they are not often watered. *Miller*'s Gardners Dict.

The grey, or white leaved kind, is eafily propagated by cuttings, planting them in light earth, and frequently watering them till they have taken root, and then the plants are to be removed into a warm fituation. This method is vaftly better in regard to this particular plant, than the raifing from feeds; becaufe, when fo raifed, it is very apt to degenerate, and lofe the whitenefs of its leaves, which are its principal beauty. See JACOBÆA.

RAHAS, in ichthyology, a name given by fome authors to the *torpedo*, or cramp fifh. It is a fpecies of the ray fifh, diftinguifhed by Artedi, by the name of the *raia tota levis*, the wholly fmooth ray. See TORPEDO, *Cycl.*

RAIA, in the Linnæan fyftem of zoology, the name of a diftinct genus of fifhes of the general order of the chondropterygii. The diftinguifhing characters of this genus are, that the body is flatted, and the apertures of the gills are five on each fide. *Linnæi* Syft. Natur. p. 51.

In the Artedian fyftem of ichthyology, the characters of this genus of fifhes are thefe. They are of the chondropterygious kind. The apertures of the bronchia are five on each fide, and are fituated on the breaft a little below the mouth. The head and the whole body are of a remarkably depreffed or flatted figure. The fides are terminated in broad fins, which are in the place of pectoral ones in other fifhes. The eyes are placed in the upper fide of the head, and the mouth generally in the lower. There is on each fide of the head a foramen behind the eyes. And the tail is generally long and flender.

Of thofe *raiæ* which have obtufe or granulous teeth, the following are the fpecies. 1. The oblong *ray* with one row of fpines, along the middle of the back. This is the *rhinobatus* and *fquatino-raia* of authors. 2. The prickly *ray*, with teeth like tubercles, and a tranfverfe cartilage in the belly. This is the *raia clavata* of authors, and our *thornback* and *maid*. 3. The fmooth bodied *ray*, with a long fpine ferrated on one fide in the tail, which has no fin. This is the *paftinacha marina* of authors. 4. The fmooth bodied *ray*, with generally two fpines ferrated behind in the tail, without a fin. This is the *altavela* of the Italians. 5. The fmooth bodied *ray* with a fingle long ferrated fpine in the tail, with a fin on it. This is the fifh, called by authors the *aquila marina*.

Of the *rays* with fharp teeth, the following are the known fpecies. 1. The *ray* with the whole back armed with fpines, with two rows of them on the tail, and a fingle row about the eyes. This is the *ray* called the white horfe *ray*, or *raja tota afpera* of authors. 2. The *ray* with the back and belly fmooth, but with a row of fpines about the eyes, and three rows of them upon the tail. This is the *raja lævis oculata* of authors. 3. The variegated *ray* with two prickly tubercles on the middle of the back. This is the *raja oxyrhincos major* of authors. It fometimes has two fins,

fome-

fometimes only one on the tail. 4. The *ray* with the middle of the back fmooth, and with only one row of fpines on the tail. This is the *fkate* fifh or *flair*. It is of a greyifh colour, variegated with blackifh fpots, and grows very large. 5. The wholly fmooth *ray*. This is the famous *torpedo*, or cramp fifh. See the article TORPEDO, *Cycl.*

Rays are generally divided by authors into the fmooth and the prickly. The fmooth are what we call the *fkates* and *flairs*: the prickly we call *thornbacks*, and the young ones of both kinds *maids*. But Willughby thinks they are more regularly divided into two orders, the one containing thofe which have teeth, the other thofe which have none. *Willughby's* Hift. Pifc. p. 68.

RAJANIA, in botany, a name given by Linnæus to a genus of plants. The different fpecies of which are made to compofe two genera in Plumier, under the names of *jan-raia* and *bryoniæ* fpecies. The characters of the genus are thefe. It produces feparate male and female flowers; in the male flower the perianthium is divided into fix fegments, which are oblong, and pointed, and ftand clofe in the bafis, fo as to form a fort of bell, and expand more at their points. There are no petals, and the ftamina are fix briftly filaments fhorter than the cup, and terminated by fimple apices. In the female flower the perianthium is one leaved, campanulated, and ftands upon the germen, but afterwards withers away. This alfo is divided into fix fegments at the edge. There are no petals, and the germen of the piftil is compreffed, and edged, with a membrane on one fide. The ftyles are three in number, and are of the length of the cup. The ftigmata are fimple and obtufe. The fruit is roundifh, and has a membrane growing on one fide, which, in fine, fpreads almoft round it; in this is contained a fingle feed of a roundifh colour. *Linnæi* Gen. Pl. p. 479. *Plum.* 29 and 98.

RAIL (*Cycl.*)—RAIL, or *water* RAIL, in zoology, the name of the *rollus aquaticus* of authors, a bird of the moorhen kind, but fmaller than the common moorhen. See ROLLUS.

Fife RAILS, in a fhip. See FIFE.

RAIN (*Cycl.*)—Vehement *rains* in many countries are found to be attended with barrennefs and poornefs of the lands, and mifcarriage of the crops in the fucceeding year: and the reafon is plain; for thefe exceffive ftorms wafh away the fine mould into the rivers, which carry it into the fea, and it is a long time before the land recovers itfelf again. The remedy to the famine, which fome countries are fubject to from this fort of mifchief, is the planting large orchards and groves of fuch trees, as bear efculent fruit; for it is an old obfervation, that in years, when grain fucceeds worft, thefe trees produce moft fruit of all. It may partly be owing to the thorough moiftening of the earth, as deep as their roots go, by thefe rains, and partly to their trunks ftopping part of the light mould carried down by the rains, and by this means furnifhing themfelves with a coat of new earth. Phil. Tranf. N° 90.

Preternatural RAINS. We have numerous accounts in the hiftorians of our own, as well as other countries of *preternatural rains*, fuch as the *raining* of ftones, of duft, of blood, nay, and of living animals, as young frogs, and the like. We are not to doubt the truth of what thofe who are authors of veracity and credit relate to us of this kind, fo far as to fuppofe that the falling of ftones and duft never happened; the whole miftake is, the fuppofing them to have fallen from the clouds; but as to the blood and frogs, it is very certain that they never fell at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine ftrictly whatever is reported of this kind, and is not to fuffer himfelf to be deceived.

There are two natural methods by which quantities of ftones and duft may fall in certain places, without their having been generated in the clouds, or fallen as *rain*. The one is by means of hurricanes; the wind which we frequently fee tearing off the tiles of houfes, and carrying them to confiderable diftances, being equally able to take up a quantity of ftones, and drop them again at fome other place. But the other, which is much the moft powerful, and probably the moft ufual way, is for the eruptions of volcano's, and burning mountains, to tofs up, as they frequently do, a vaft quantity of ftones, afhes, and cinders, to an immenfe height in the air; and thefe being hurried away by the hurricanes and impetuous winds, which ufually accompany thofe eruptions, and being in themfelves much lighter than common ftones, as being half calcined, may eafily be thus carried to vaft diftances, and there falling in places where the inhabitants know nothing of the occafion, they cannot but be fuppofed by the vulgar to fall on them from the clouds. It is well known, that in the great eruptions of Ætna and Vefuvius, fhowers of afhes, duft, and fmall cinders, have been feen to obfcure the air, and overfpread the furface of the fea for a great way, and cover the decks of fhips; and this at fuch a diftance, as it fhould appear fcarce conceivable that they fhould have been carried to; and probably, if the accounts of all the fhowers of thefe fubftances mentioned by authors be collected, they will all be found to have fallen within fuch diftances of vulcano's; and if compared, as to the time of their falling, will be found to correfpond in that alfo with the eruptions of thofe mountains. We have known inftances of the afhes from Vefuvius having been carried thirty, nay forty leagues, and peculiar accidents may have carried them yet farther. It is not to be fuppofed that thefe fhowers of ftones and duft fall for a continuance, in the manner of fhowers of *rain*, or that the fragments or pieces are as frequent as drops of water; it is fufficient that a number of ftones, or a quantity of duft, fall at once on a place, where the inhabitants can have no knowledge of the part from whence they come, and the vulgar will not doubt their dropping from the clouds. Nay, in the canton of Berne in Swifferland, the inhabitants accounted it a miracle that it rained earth and fulphur upon them, at a time that a fmall vulcano terrified them; and even while the wind was fo boifterous, and hurricanes fo frequent, that they faw almoft every moment the duft, fand, and little ftones torn up from the furface of the earth in whirlwinds, and carried to a confiderable height in the air, they never confidered, that both the fulphur thrown up by the vulcano, and the duft, &c. carried from their feet muft fall foon after fomewhere. It is very certain that in fome of the terrible ftorms of large hail, where the hail-ftones have been of many inches round, that on breaking them there have been found what people have called ftones in their middle; but thefe obfervers needed only to have waited the diffolving of one of thefe hail-ftones, to have feen the ftone in its center difunite alfo, it being only formed of particles of loofe earthy matter, which the water, exhaled by the fun's heat, had taken up in extremely fmall moleculæ with it; and this only having ferved to give an opake hue to the inner part of the congelation, to which the freezing of the water alone gave the apparent hardnefs of ftone.

The *raining* of blood has been ever accounted a more terrible fight, and a more fatal omen than the other *preternatural rains*, already mentioned. It is very certain that nature forms blood no where but in the veffels of animals, and therefore fhowers of it from the clouds are by no means to be credited. Thofe who fuppofe that what has been taken for blood, has been actually feen falling through the air, have had recourfe to flying infects for its origin, and fuppofe it the eggs or dungs of certain butter-flies, difcharged from them as they were high up in the air. But this feems a very wild conjecture, as we know of no butterfly whofe excrements, or eggs, are of fuch a colour, or whofe abode is fo high, or their flocks fo numerous, as to be the occafion of this.

It is moft probable that thefe bloody waters were never feen falling, but that people feeing the ftanding waters blood coloured, were affured, from their not knowing how it fhould elfe happen, that it had *rained* blood into them. A very memorable inftance of this there was at the Hague in the year 1670. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar on finding their lakes and ditches full of blood, as they thought, and having been certainly full of water the night before, they agreed it muft have *rained* blood in the night; but a certain phyfician went down to one of the canals, and taking home a quantity of this blood coloured water, he examined it by the microfcope, and found that the water was water ftill, and had not at all changed its colour, but that it was full of prodigious fwarms of fmall red animals, all alive, and very nimble in their motions, whofe colour, and prodigious number, gave a red tinge to the whole body of the water they lived in, on a lefs accurate infpection. The certainty that this was the cafe, did not however perfuade the Hollanders to part with the miracle; they prudently concluded, that the fudden appearance of fuch a number of animals was as great a prodigy, as the *raining* of blood would have been; and are affured to this day, that this portent foretold the fcene of war and deftruction which Lewis the fourteenth afterwards brought into that country, which had before enjoyed forty years uninterrupted peace.

The animals which thus colour the water of lakes and ponds, are the *pulices arborefcentes* of Swammerdam, or the water fleas with branched horns. Thefe creatures are of a reddifh yellow, or flame colour; they live about the fides of ditches, under weeds, and among the mud, and are therefore the lefs vifible, except at a certain time, which is in the end of May or beginning of June; it is at this time that thefe little animals leave their receffes to float loofe about the water, to meet for the propagation of their fpecies, and by that means become vifible in the colour they give the water. This is vifible, more or lefs, in one part or other of almoft all ftanding waters at this feafon; and it is always at this feafon that the bloody waters have alarmed the ignorant.

The *raining* frogs is a thing not lefs wonderful in the accounts of authors who love the marvellous, than thofe of blood or of ftones, and this is fuppofed to happen fo often, that there are multitudes who pretend to have been eye-

witnesses of it. These *rains* of frogs always happen after very dry seasons, and are much more frequent in the hotter countries than the cold ones. In Italy they are very frequent, and it is not uncommon to see the streets of Rome swarming both with young frogs and toads in an instant, in a shower of *rain*; they hopping every where between the people's legs as they walk, though there was not the least appearance of them before. Nay, they have been seen to fall through the air down upon the pavements. This seems a strong circumstance in favour of their being *rained* down from the clouds, but when strictly examined, it comes to nothing; for these frogs that are seen to fall, are always found dead, lamed, or bruised by the fall, and never hop about as the rest; and they are never seen to fall, except close under the walls of houses, from the roofs and gutters of which they have accidentally slipped down. People, who love to add to strange things yet stranger, affirm that people have had the young frogs fall into their hats in the midst of an open field, but this is idle and wholly false.

People, who cannot agree to their falling from the clouds, have tried to solve the difficulty of their sudden appearance, by supposing them hatched out of the egg, or spawn, by these rains. Nay, some have supposed them made immediately out of the dust; but there are unanswerable arguments against all these suppositions. Equivocal generation, or the spontaneous production of animals out of dust, being now wholly exploded. The fall from the clouds must destroy and kill these tender and soft bodied animals; and they cannot be at this time hatched immediately out of eggs; because the young frog does not make its appearance from the egg in this form, but has its hinder legs enveloped in a skin, and is what we call a tadpole; and the young frogs are at least an hundred times larger at this time of their appearance, than the egg from which they should be hatched.

It is a certainty that the frogs, which make their appearance at this time, were hatched, and in being long before, but that the dry seasons had injured them, and kept them sluggishly in holes, or coverts, and that all the *rain* does, is the enlivening them, giving new spirits, and calling them forth to seek new habitations, and enjoy the element they were destined, in great part, to live in. Theophrastus, the greatest of all the naturalists of antiquity, has affirmed the same thing. We find that the error of supposing these creatures to fall from the clouds was as early as that author's time, and also that the truth, in regard to their appearance, was as early known; though, in the ages since, authors have taken care to conceal the truth, and to hand down to us the error. We find this venerable sage, in a fragment of his on the generation of animals which appear on a sudden, bantering the opinion, and asserting that they were hatched and living long before. The world owes, however, to the accurate Seignior Redi the great proof of this truth, which Theophrastus only has affirmed; for this gentleman dissecting some of these new appearing frogs, found in their stomachs herbs, and other half digested food, and openly shewing this to his credulous countrymen, asked them whether they thought that nature, which engendered, according to their opinion, these animals in the clouds, had also been so provident as to engender grass there also for their food and nourishment.

To the *raining* of frogs we ought to add the *raining* of grasshoppers and locusts, which have sometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the least pretence for the supposing that these animals descended from the clouds, but that they appeared on a sudden in prodigious numbers. The naturalist, who knows the many accidents attending the eggs of these, and other the like animals, cannot but know that some seasons will prove particularly favourable to the hatching them, and the prodigious number of eggs, that many insects lay, could not but every year bring us such abundance of the young, were they not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the species by a very numerous stock of seeds, of which perhaps not one in five hundred need take root, in order to continue an equal number of plants. As it is thus also in regard to insects, it cannot but happen, that if a favourable season encourage the hatching of all those eggs, a very small number of which alone were necessary to continue the species, we must, in such seasons, have a proportionate abundance of them. We had lately in London such a prodigious swarm of the little beetle, we call the *lady cow*, that the very posts in the streets were every where covered with them. But thanks to the progress of philosophy among us, we had no body to assert that it *rained* cow ladies, but contented ourselves with saying that it had been a favourable season for their eggs. The late prodigious number of a sort of grub which did vast mischief among the corn and grass, by eating off their roots, might also have been supposed to proceed from its having *rained* grubs by people fond of making every thing a prodigy; but our knowledge in natural history assured us, that these were only the hexapode worms of the common hedge beetle, called the *cock chafer*.

The *raining* of fishes has been a prodigy also much talked of in France, where the streets of a town at some distance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houses, &c. were found in a manner covered with fishes of various sizes. No body here made any doubt of these having fallen from the clouds; nor did the absurdity of fish, of five or six inches long, being generated in the air, at all startle the people, or shake their belief in the miracle, till they found, upon enquiry, that a very well stocked fish-pond, which stood on an eminence in the neighbourhood, had been blown dry by the hurricane, and only the great fish left at the bottom of it, all the smaller fry having been tossed into their streets.

Upon the whole, all the supposed marvellous *rains* have been owing to substances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

In Silesia, after a great dearth of wheat in that country, there happened a violent storm of wind and rain, and the earth was afterwards covered, in many places, with small round seeds. The vulgar cried out that providence had sent them food, and that it had *rained* millet; but these were, in reality, only the seeds of a species of veronica, or speedwell, very common in that country, and whose seeds being just ripe at that time, the wind had dislodged them from their capsules, and scattered them about. In our own country, we have histories of *rains* of this marvellous kind, but all fabulous. It was once said to *rain* wheat in Wiltshire, and the people were all alarmed at it as a miracle; till Mr. Cole shewed them, that what they took for wheat was only the seeds, or kernels of the berries of ivy, which being then fully ripe, the wind had dislodged from the sides of houses, and trunks of trees, on which the ivy which produced them crept.

And we even once had a *raining* of fishes near the coast of Kent in a terrible hurricane, with thunder and lightning. The people who saw small sprats strewed all abouts afterwards, would have it that they had fallen from the clouds; but those who knew how far the high winds have been known to carry the sea water, did not wonder that they should be able to carry small fish with it so small a part of the way. Philos. Transf.

RAINS, in the sea language, that tract of the sea to the northwards of the equator, between four and ten degrees of latitude, and lying between the meridian of Cape Verde and that of the eastermost islands of the same name. They call this tract the *rains*, because there are almost continual calms, constant *rains*, and thunder and lightning to a strange degree there; and the winds, when they do ever blow, are only small uncertain gusts, and shift about all round the compass; so that ships are sometimes here detained a long while, and can make but very little way.

RAIN *fowl*, an English name given by many to the common green wood-pecker, or *picus viridis*, from an observation that it is always most clamorous when *rainy* weather is coming on. The Latins have, for the same reason, called it the *pluvialis avis*. See the article PICUS.

Animalcules in RAIN-*water*. The accurate Mr. Lewenhoek has observed, that there are no living creatures to be discerned in fresh *rain-water*, but that after it has stood some days, it will be found to abound with great numbers of animalcules, so small, that they are to a mite what a bee is to a horse. In some days more animalcules much larger are discovered.

Another very remarkable kind is discovered in *rain-water*, after standing some time; these have two little horns, which are in continual motion. The space between the horns is flat, though the body is round, but tapering a little toward the end, where there is a tail four times as long as the body, and of the thickness of the thread of a spider's web. These are so small, that many hundred of them are not equal to a grain of sand; and if they meet with any little filament in the water, they are usually entangled in it, and use great efforts to disengage their tails.

Another animalcule there also is in *rain-water*, of an oval figure, with the head at the smaller end. These have several feet extremely minute and fine, and they can, at pleasure, contract their bodies into a round shape, which they usually do as the water dries away. A third sort Mr. Lewenhoek observed also, twice as long as broad, and eight times smaller than the last; these also had small feet, and were very nimble. But the briskest of all were a yet greatly smaller kind; these were not of a thousandth part of the size of a louse's eye, and they moved round with incredible swiftness. *Baker*'s Microscop. p. 82.

RAISE, in the manege, is used for working; thus to *raise* a horse upon corvets, caprioles, or pesades, is to make him work at corvets, caprioles, &c.

RAISE is likewise used for placing a horse's head right, and making him carry well, and hindring him to carry low, or to arm himself.

RAISINS (*Cycl.*)—RAISIN *brandy*, a name given by our distillers to a very clean and pure spirit, procured from *raisins* fermented

fermented only with water. Thus treated, they yield a ſpirit ſcarce at all diſtinguiſhable from ſome of the wine ſpirits; for there are as many kinds of wine ſpirits, as there are of grapes. The coarſer the operation of diſtilling is performed in this caſe, the nearer will be the reſemblance of the wine ſpirit; that is, there will be moſt of this flavour in the ſpirit, when as much as can be of the oil is thrown up with a galloping heat.

The diſtillers are very fond of the wine ſpirit, with which they hide and diſguiſe the taſte of their nauſeous malt, and other ſpirits; and in defect of that ſpirit, this of *raiſins*, made in this coarſe manner, will go almoſt as far. It is indeed ſurpriſing how extenſive the uſe of theſe flavouring ſpirits is, ten gallons of *raiſin* ſpirit, or ſomewhat leſs of the wine ſpirit, being often ſufficient for a whole piece of malt ſpirit, to take off its native flavour, and give it an agreeable vinoſity. It is no wonder, therefore, that the diſtillers, and ordinary rectifiers, are ſo fond of this, as it is a good cloak for their defects, and the imperfection of their proceſſes.

When *raiſin brandy* is intended for common uſe, the fire ſhould be kept ſlower and more regular in the diſtillation, and the ſpirit, though it hath leſs of the high flavour of the grape, will be more pleaſant and more pure. *Shaw's* Eſſay on Diſtillery.

RAKE (*Cycl.*)—Rake, in the manege. A horſe *rakes*, when being ſhoulder-ſplait, or having ſtrained his fore-quarter, he goes ſo lame, that he drags one of his fore legs in a ſemicircle; which is more apparent when he trots, than when he paces.

Rake, in mining, is the ſame with a vein. See Vein.

RAM, (*Cycl.*) *aries*, in zoology, the male of the ſheep kind. See the article Ovis.

Ram *head*, on board a ſhip, the name of a great block belonging to the fore and main halliards. It hath in it three ſhivers, into which the halliards are put, and at its head the tyes are reeved into an hole made there for that purpoſe.

RAMADAN (*Cycl.*)—The *ramadan* happens at different ſeaſons of the year, and when it is in the ſummer, is very hard on the labourers, who are not allowed to drink, but only to waſh their mouths. This month once in thirty-three years is in every ſeaſon of the year, the Turkiſh month being lunar, and they beginning at the day they can ſee the moon; whereas the Jews begin their account from the day the moon makes, which is a day before the Turks. *Pocock's* Egypt, p. 184.

RAMAG, a word uſed by ſome of the chemical writers to expreſs aſhes.

RAMAGE *falcons*. See the articles Brancher and Falcon.

RAMAI, in natural hiſtory, a name given by many old writers to bole armenic.

RAMALIS *vena*, a name given by ſome anatomical authors to the *vena portæ*.

RAMED, a name given by ſome chemical writers to rhubarb.

RAMESAN, an oriental term for a month of faſting, very religiouſly obſerved among the Turks. See Ramadan.

RAMEX, a word uſed by ſome as a name for a hernia, or rupture.

RAMIGRI, a word uſed by ſome writers as a name for colophony.

RAMINGUE, in the manege. A horſe gets this name that is reſty, and reſiſts or cleaves to the ſpurs; that is, defends himſelf with malice againſt the ſpurs; ſometimes doubles the reins, and frequently yerks to favour his diſobedience. See the articles Ticklish and Double.

RAMOSE *leaf*, in botany. See Leaf.

RAMPIN, in the manege. See Toe.

RAMPION, in botany. See Rapunculus.

RAMULOSE *leaf*, *ramuloſum folium*, among botaniſts. See the article Leaf.

RAMUS, (*Cycl.*) in the anatomy of plants, a name given to the firſt or lateral branches, which go off from the petrolium, or middle rib of a leaf. The ſubdiviſions of theſe are called *ſurculi*, and the final diviſions of theſe, into the moſt minute of all, are by ſome called *capillamenta*; but in general, both theſe kinds are comprehended under the name of *ſurculus*. Act. Erudit. 1722.

RAN, in our old writers, is uſed for open or public robbery, ſo manifeſt that it cannot be denied. Ran *dicitur aperta rapina quæ negari non poteſt*. *Lamb.* 125. Leg. Canut. c. 58. Hence it is to this day vulgarly ſaid of one, who takes the goods of another injuriouſly and violently, that he has taken or ſnatched all he could *rap* and *ran*. Terms of Law. *Blount*, *Cowel*.

RANA, the *frog*, in zoology, a very well known animal of the amphibious kind, the characters of it are; that the body is naked, and is in one part of its life furniſhed with a tail.

The feet of the *frog* are webbed, for the better ſwimming, and it has very ſtrong muſcles in the hinder part of its body to aſſiſt it in leaping. The lungs of the *frog* are different from thoſe of all other animals; they are only a ſort of membranaceous bladders, with ſeveral tubercles, by means of which they reſemble the fruit of the firs, or pines: theſe, when once inflated, do not immediately become flaccid, as in other animals, but remain in that ſtate as long as the creature pleaſes. The creature can remain a long time under water, and has been kept ſo for ſeveral days by tying it down, and received no hurt from it. It is a very long lived animal; and even if its belly be opened, and the inteſtines, and all the viſcera, taken out, it will continue its leaping, and all its other motions, as if nothing had happened to it, for a conſiderable time; but if the nerve of one of the hinder legs be cut, it loſes all power of uſing that limb on the inſtant. *Ray's* Synop. Quad. p. 247.

The *frog* differs from all creatures in the manner of its generation. It no way reſembles any of the quadrupeds in this particular, and though in ſome ſort it approaches to the nature of fiſhes, yet it differs from them alſo in many things. The egg of the *frog* is a ſmall black ſpot, enveloped in a mucilaginous ſubſtance; in this egg is contained the embryo *frog*, which, on the breaking of the egg in hatching, comes forth in form of a tadpole. This young animal is for ſome time nouriſhed by the gelatinous matter which envelops the eggs, but it does not conſume the whole of it; for the particles of water making way by degrees into it, divide its parts, and it ſoon becomes expanded, frees itſelf from the living animals, and floats on the ſurface of the water, or at a ſmall depth in it, in form of a thin cloud: this, though it now no longer ſerves for food to the young creature, is however of ſome ſervice to it, ſerving it as an aſylum, or place of reſt and ſafety, when tired with ſwimming.

The egg of the *frog* therefore is, in ſome degree, analogous to that of an inſect of the winged kind, which is to go through a metamorphoſis before it arrives at its perfect ſtate; for it hatches into the tadpole, as the egg of a butterfly into a caterpillar, and arrives at that its ultimate ſtate, after a determinate time ſpent in the other. In this it differs from the generation of fiſhes, the eggs of whoſe ſpawn hatch into perfect fiſhes, which go through no change; and it differs from all in the gelatinous ſubſtance, which envelops the egg, and ſerves as the firſt food to the fœtus.

The eggs are indeed, when nicely examined, found to be encloſed in a double liquor, a more pellucid and thin one within the gelatinous one, which ſerves as the general covering to the whole ſeries of eggs; and it is this thin one which it principally feeds on when firſt hatched, and which ſerves to the ſame purpoſes as the white of an egg in the fowl kind.

There is alſo an opinion that the male ſperm of the *frog* is depoſited on the ſpawn of the female after it is laid. *Ray's* Syn. Quad. p. 249.

Rana *arborea*, the *tree frog*, in zoology. See Ranunculus *viridis*.

Rana *piſcatrix*, the *toad fiſh*, *frog fiſh*, or, as it is called by ſome, the *ſea devil*, a very remarkable ſpecies of fiſh, of a middle nature between the cartilaginous and bony fiſhes. In ſhape and figure it reſembles a tadpole. Its head is extremely large, being equal, or more than ſo, to the reſt of the body, and of a circular figure. The opening of its mouth is ſurpriſingly great, and its lower jaw is above a finger longer than the upper. Both jaws, but particularly the under one, are armed with a great number of long and ſharp teeth, and the longer ones of the under jaw are all moveable inwards. The back is flat, and of a bluiſh green colour, mottled with a few white ſpots. The eyes are pearly in the iris, and a tranſverſe ſtreak of white is drawn acroſs the pupil. In the upper part of the head, at half a finger's breadth diſtance from the angle of the upper jaw, are placed two briſtles, the fore one is ſix fingers long, the hinder one four; and in the middle of his back, lower down, are three more, which ſerve in the place of fins. Over the upper jaw there are, on each ſide, two ſharp thorns, and there are thorny tubercles all about the eyes; and on the middle of the back, not far from the tail, there is a fin with ten rays. The tail is not forked, but the rays are branched, and all ſtand out a little beyond the fin, and are hooked. In the under part of the body, juſt under the throat, there are two fins like a mole's feet, each compoſed of five rays, or fingers. There are two others on the edge of the body, and the extremity of all theſe, as alſo of the tail, is black. It has only three branchiæ on one ſide. It has either no noſtrils, or elſe they are hid within the head, and has a ſort of membranous rim running all round the commiſſures of its ſides and belly. Its fleſh, when boiled, taſtes like that of the *frog*. See Tab. of Fiſhes, N° 8. and *Willughby's* Hiſt. Piſc. p. 85.

RANCE, in natural hiſtory. See Cibdeloplacia.

RANGIFER, the *rein deer*, an animal very common in all the northern nations, and called by ſome authors *tarandus* and *machlis*. It is of the ſhape of a ſtag, but its body is thicker, and its whole make much more robuſt and ſtrong. The breaſt is thick, covered with very long hairs. The legs very

very hairy and the hoofs moveable, for the creature expands and opens them in going; it is an extremely swift, as well as strong animal; its horns are very long, and finely branched, and particularly run out immediately from the forehead into two fingered branches; in the middle there is a little branch, like the joints in the stalks of some plants; and thence again they are divided into broad fingered segments. They differ from the horns of the elk in their length, and from those of the stag or red deer in their breadth, and from both, in the multitude of branches, and in their colour which is white. The lower branches, which fall very near the forehead, are said to be used by the creature to break the ice, when the waters are frozen over, that he may get drink. It feeds on shrubs and plants, and on the moss, which it finds on the earth and upon the barks of trees.

It is of prodigious use, as a beast of carriage to the Laplanders, and almost all the other nations far north. Scheffer alledges from Tornæus, that the *rein deer*, though a cloven footed animal, and plainly of the deer kind, does not chew the cud. This, however, is wholly disbelieved by the more accurate naturalists. *Ray's* Sept. Quad. p. 88.

RANINÆ *venæ*, a name given by anatomists to the larger veins under the tongue.

RANIO, in natural history, a name given by some writers to bole armenic.

RANK (*Cycl.*)—RANK *keel*, in a ship. See KEEL, *Cycl.*

RANUNCULUS, *crowfoot*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the rosaceous kind, consisting of several leaves disposed in a circular order, and usually standing in a many leaved cup. The pistil arises from the center of the flower, and finally becomes a fruit of a roundish, oval, or spiked shape, to the axis of which there grow, as to a placenta, a great number of seeds, which are usually naked.

The species of *ranunculus* enumerated by Mr. Tournefort are very many, and for the sake of order, in so large a number, they are divided into several sections. 1. Those which have the appearance of the anemonies. 2. Those which have roundish leaves. 3. Those usually known by the name of the Asiatic *ranunculuses*. 4. The smooth leaved *ranunculuses*. 5. The aconite or geranium leaved *ranunculuses*. 6. The fine leaved *ranunculuses*; and 7. The long leaved *ranunculuses*. *Tourn.* Inst. p. 285.

The species of the *anemony ranunculuses* are these. 1. The yellow wood *ranunculus*. 2. The single yellow flowered wood *ranunculus*, with smaller and more deeply divided leaves. 3. The common white wood *ranunculus*, called the white wood anemony. 4. The purple flowered wood *ranunculus*, commonly called the purple wood anemony. 5. The purplish red wood *ranunculus*. 6. The double purple wood *ranunculus*. 7. The double white wood *ranunculus* with a border of leaves. 8. The common double white wood *ranunculus*. 9. The trifoliate white wood *ranunculus*, commonly called the trefoil wood anemony. 10. The large leaved blue flowered wood *ranunculus* of the Apennine mountains. 11. The smaller leaved Apennine blue wood *ranunculus*. 12. The wood *ranunculus* with small blue flowers. 13. The double violet coloured wood *ranunculus*. Ibid. p. 286.

Of the roundish leaved *ranunculuses*, the species are these. 1. The round leaved wood *ranunculus*, commonly called Tragus's sweet *crowfoot*. 2. The spring wood *crowfoot* with marsh marygold or thora leaves. 3. The Virginian wood *crowfoot* with soft leaves and small flowers. 4. The large *crowfoot* with asphodel roots, and sowbread leaves. 5. The smaller *crowfoot* with asphodel roots and sowbread leaves. 6. The larger round leaved spring *crowfoot* called little celandine or pilewort. 7. The smaller round leaved spring *crowfoot* called the common pilewort. 8. The smaller round leaved spring *crowfoot*, or celandine, with spotted leaves. 9. The smaller round leaved spring *crowfoot*, or little celandine, with double flowers. 10. The smaller round leaved spring *crowfoot*, or celandine, with two rows of petals. 11. The mountain *crowfoot* with leaves like those of the parnassia. 12. The alpine *crowfoot* with water caltrop leaves. 13. The ivy leaved water *crowfoot* with very small white flowers. 14. The American water *crowfoot* with asarabacca leaves, and flowers in umbels at the joints of the stalks. 15. The little smallage leaved rock *crowfoot* with tuberose reticulated roots. 16. The ground ivy leaved knotty rooted Portugal *crowfoot*. 17. The round leaved creeping *crowfoot* with echinated seeds. 18. The marsh *crowfoot* with echinated seeds. 19. The cretic echinated starry *crowfoot*. 20. The broad leaved bullated asphodel rooted *crowfoot*. 21. The small flowered round leaved Portugal *crowfoot*. 22. The double flowered broad leaved autumnal *crowfoot*. 23. The trifoliate spring *crowfoot* with single blue flowers. 24. The trifoliate spring *crowfoot* with violet coloured flowers. 25. The trifoliate spring *crowfoot* with pale purplish flowers. 26. The trifoliate spring *crowfoot* with single bright red flowers. 27. The trifoliate spring *crowfoot* with single flesh coloured flowers. 28. The trifoliate spring *crowfoot* with single greyish flowers. 29. The trifoliate spring *crowfoot* with single large white flowers. 30. The trifoliate spring *crowfoot* with smaller single white flowers. 31. The trifoliate spring *crowfoot* with single white flowers edged with red. 32. The trifoliate spring *crowfoot* with double blue flowers. 33. The trifoliate spring *crowfoot* with double purple flowers. 34. The trifoliate spring *crowfoot* with double flesh coloured flowers. 35. The trifoliate spring *crowfoot* with double variegated flowers. These plants, properly named trifoliate *crowfoots*, are the spring garden flowers, commonly called *hepaticas*.

Of the third set of *ranunculuses*, commonly called the Asiatic *ranunculuses*, the species are these. 1. The knobby rooted Asiatic *ranunculus* with very small single scarlet flowers. 2. The branched knobby rooted *ranunculus*. 3. The knobby rooted *ranunculus* with yellow flowers, being variegated with red. 4. The knobby rooted *ranunculus* with white flowers. 5. The knobby rooted *ranunculus* with snow white flowers. 6. The knobby rooted *ranunculus* with pale yellow flowers streaked with red. 7. The knobby rooted *ranunculus* with single yellow flowers. 8. The knobby rooted *ranunculus* with single flowers, of a deep yellow, with red bottoms and red edges. 9. The single whitish flowered Asiatic *ranunculus*. 10. The single *ranunculus* with a red lead coloured flower with yellow edges. 11. The rose coloured *ranunculus* with white edges, and streaks of white in the flower. 12. The butterfly *ranunculus* with yellow flowers spotted with red. 13. The single crimson sweet scented *ranunculus*. 14. The piony *ranunculus*, or the large bloody purple flowered kind. 15. The Aleppo *ranunculus* with flowers streaked with yellow and red. 16. The *ranunculus* with a very wide, open, red lead coloured flowers. 17. The lemon coloured and red *ranunculus*. 18. The white proliferous *ranunculus* with crimson stamina. 19. The asphodel rooted *ranunculus* with blood coloured flowers. 20. The asphodel rooted *ranunculus* with a reddish purple flower. 21. The asphodel rooted *ranunculus* with yellow flowers with red veins. 22. The double *ranunculus*, variegated with yellow and red, called by the French the *seraphique*. 23. The proliferous asphodel rooted *ranunculus* with red coloured flowers. 24. The asphodel rooted *ranunculus* with a very large blood coloured flower. 25. The asphodel rooted *ranunculus* with yellow flowers streaked with red. 26. The asphodel rooted *ranunculus* with double greenish white flowers. 27. The asphodel rooted *ranunculus* with small double white flowers streaked with red. 28. The asphodel rooted *ranunculus* with great double white rose-like flowers. 29. The asphodel rooted *ranunculus* with great double violet coloured flowers. 30. The great Constantinople *ranunculus* with scarlet flowers. 31. The great Constantinople *ranunculus* with elegantly variegated flowers. 32. The Roman giant *ranunculus* with a red lead coloured flower. 33. The giant Roman *ranunculus* with very double flowers, variegated with red and yellow. *Tourn.* Inst. p. 288.

Of the set of tender leaved *crowfoots*, the species are these. 1. The late flowering rue leaved *ranunculus* with double gold yellow flowers. 2. The early rue leaved *ranunculus* with bright red flowers. 3. The tender leaved asphodel rooted mountain *ranunculus*. 4. The horn like leaved *ranunculus* with foliated seeds, collected into spikes, called by many the smaller cow wheat. 5. The common corn *ranunculus* with echinated seeds. 6. The greater narrow leaved woolly *ranunculus* with asphodel roots. 7. The lesser narrow leaved woolly grumose rooted *ranunculus*. 8. The smallage leaved asphodel rooted woolly *ranunculus*. 9. The fumitory leaved Alpine *ranunculus*. 10. The purple mountain *ranunculus* with hairy cups. *Tourn.* Inst. p. 289.

Of the set of aconite or crane's bill leaved *crowfoots*, the species are these. 1. The upright acrid meadow *crowfoot*. 2. The upright acrid meadow *crowfoot* with spotted leaves. 3. The single many flowered meadow *crowfoot*. 4. The upright *crowfoot* with pale hairy leaves. 5. The upright or sweet or not acrid meadow *crowfoot*. 6. The great sallad *crowfoot*. 7. The common hairy creeping field *crowfoot*. 8. The common hairy creeping meadow *crowfoot* with leaves variegated with white. 9. The round rooted meadow *crowfoot*. 10. The lesser round rooted meadow *crowfoot*. 11. The little field *crowfoot* with trifid leaves. 12. The annual hairy field *crowfoot* with extremely small flowers. 13. The double flowered erect garden *crowfoot*. 14. The great hairy creeping double flowered *crowfoot*. 15. The garden *crowfoot* with bending heads. 16. The double flowered sweet *crowfoot*. 17. The double flowered round rooted *crowfoot*. 18. The tuberose rooted proliferous double *crowfoot*. 19. The grumose rooted *crowfoot* with leaves like those of the common round rooted kind. 20. The Cretic asphodel rooted *crowfoot*. 21. The round leaved procumbent alpine *crowfoot* with small flowers. 22. The low round leaved alpine *crowfoot* with larger flowers. 23. The tall hairy white flowered mountain *crowfoot*. 24. The low hairy mountain *crowfoot* with Narcissus flowers. 25. The purple flowered hairy mountain *crowfoot*. 26. The aconite leaved moun-

mountain *crowfoot* with large white flowers. 27. The aconite leaved mountain *crowfoot* with ſmaller white flowers. 28. The aconite leaved mountain *crowfoot* with double white flowers. 29. The aconite leaved mountain *crowfoot* with large ſingle yellow flowers. 30. The *crowfoot* with leaves like thoſe of the knotty rooted crane's bill. 31. The hairy mountain *crowfoot* with very broad leaves. 32. The crane's bill leaved downy mountain *crowfoot*. 33. The yellow flowered fine leaved mountain *crowfoot*. 34. The woolly mountain *crowfoot* with leaves like thoſe of the common meadow *crowfoot*. 35. The rock *crowfoot* with large flowers. 36. The roundiſh leaved rock *crowfoot*. 37. The very hairy Montpelier *crowfoot*. 38. The ſmallage leaved hairy marſh *crowfoot*. 39. The ſmooth ſmallage leaved marſh *crowfoot*. 40. The purple flowered ſmallage leaved marſh *crowfoot*. 41. The water *crowfoot* with ſome of the leaves roundiſh, and others capillaceous. Ibid. p. 290.

Of the capillaceous leaved *ranunculuſes*, the ſpecies are theſe. 1. The capillaceous or fine leaved water *crowfoot*. 2. The white flowered floating water *crowfoot* with peucedanum leaves. 3. The fennel leaved *crowfoot* with roots like thoſe of black hellebore, called by authors the fine leaved black hellebore. The *conſiligo*, the *hellebore* of Hippocrates, and the *bupththalmum*, or ox eye. 4. The ſmaller or lower fennel leaved *crowfoot* with very large flowers, and jointed ſtalks. 5. The camomile leaved red flowered field *crowfoot*, commonly called the adonis flower, the pheaſant's eye, or red maithes. 6. The longer leaved chamomile *crowfoot* with orange coloured flowers. 7. The chamomile *crowfoot* with ſmall yellow flowers. 8. The betony leaved mountain *crowfoot*. Ibid. p. 291.

Of the ſet of long leaved *crowfoots* the ſpecies are theſe. 1. The graſſy leaved mountain *crowfoot*. 2. The double flowered graſſy leaved mountain *crowfoot*. 3. The bulboſe rooted graſſy leaved *crowfoot*. 4. The ſingle flowered hairy graſſy leaved *crowfoot*. 5. The many flowered hairy graſſy leaved *crowfoot*. 6. The white flowered dwarf Alpine *crowfoot* with graſſy leaves. 7. The plantain leaved mountain *crowfoot*. 8. The marſh *crowfoot* with very large plantain like leaves, commonly called the water plantain. 9. The marſh *crowfoot* with narrow plantain like leaves, called the narrow leaved water plantain. 10. The low procumbent plantain leaved water *crowfoot*, called the narrow leaved procumbent water plantain. 11. The plantain leaved water *crowfoot* with very narrow leaves. 12. The American plantain leaved water *crowfoot* with white flowers and purple cups. 13. The American water *crowfoot* with arrow head leaves. 14. The *water plantain* with very large arrow headed leaves, commonly called the great water arrow head. 15. The arrow headed *water plantain* with narrower leaves. 16. The great long leaved marſh *crowfoot*. 17. The broad plantain leaved ſpearwort with hairy edges. 18. The leſſer long leaved water *crowfoot* or ſpearwort. 19. The ſpearwort, or long leaved water *crowfoot*, with ſerrated leaves. 20. The *Bayonne ſpearwort* of Parkinſon. 21. The white flowered ſmall *ſpearwort*. 22. The graſſy leaved *crowfoot* with caudated flowers, and ſeeds arranged into long and ſlender heads, commonly called mouſe tail. Ibid. p. 292.

Several of the more beautiful ſpecies of this plant have long been cultivated in the Engliſh gardens, and are moſt of them hardy plants, and will thrive very well againſt hedges, and in ſhady borders, where they require no other care than to take up their roots every other year when their leaves decay, and part them, planting out the off-ſets into other borders.

Beſide thoſe we have been long uſed to, there have been ſome of late times brought from Turkey and from Perſia, which produce ſemi-double flowers of great beauty, and annually ripening their ſeeds; there are numbers of varieties, or as the gardeners call them new flowers continually raiſed from them. Many of theſe are finely ſcented; and the roots, when ſtrong, produce eight or ten flowers on each. The double flowered *ranunculuſes* not producing ſeeds, they are only to be propagated by parting their roots, taking off the off-ſets, which they uſually produce in great plenty.

The proper ſeaſon for planting their roots is in October. The beds in which they are planted are to be of good light ſandy earth, at leaſt a foot deep. Common paſture land is the beſt for this uſe, to which if it prove too clayey, there ſhould be added a proper quantity of ſea ſand. This mixture ſhould be turned often, and the larger ſtones and clods taken out; but it muſt not be ſkreened, or ſifted very fine, for that has been the occaſion of the loſs of many roots, both of this and other plants, by cohering into a hard clod with the wet, and rotting the roots.

The beds being prepared, ſhould lie about a fortnight to ſettle, and then drawing ſtrait and tranſverſe lines over the beds, the plants muſt be planted regularly at four inches diſtance, about an inch below the ſurface and the earth, carefully drawn over them with a rake. In November the heads will appear, and then about half an inch depth of freſh earth ſhould be added, which will greatly ſtrengthen the plants. And if it ſhould be very ſevere weather, when the heads appear above this ſecond covering, they ſhould be defended with mats laid over arched hoops. In the beginning of March the flower ſtones will appear; and when the flowering is paſt, and the leaves are decayed, the roots are to be taken up, and laid by for the October following. *Miller's* Gard. Dict. in voc.

RANUNCULUS *viridis*, in zoology, the name of an animal common in many parts of the world, and uſually known by the name of the *tree frog*, or *rana arborea*.

The creature is eaſily diſtinguiſhed from the common frog, by its being much ſmaller, and of a green colour: it uſually ſits upon the leaves of trees and ſhrubs, and makes a great noiſe in an evening, but that is rather like the ſinging of a ſmall bird than the croaking of a frog.

Theſe creatures have been kept alive many years together in glaſs veſſels, giving them flies and other ſmall inſects; and in winter, when theſe are ſcarce, they uſually become very lean and feeble; but in ſummer, when they are plentiful, they will grow fat again, as if at their liberty. This is eſteemed a poiſonous creature. *Ray's* Syn. Quad. p. 251.

RAPA, *turnep*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, which are diſpoſed in form of a croſs. The piſtil ariſes from the cup, and is at length changed into a long pod, divided into two cells, by an intermediate membrane, and ending in a long fungous horn, both of which contain roundiſh ſeeds. To this, it may be added, that the root is large, fleſhy, and eſculent.

The ſpecies of *turnep*, enumerated by Mr. Tournefort, are theſe. 1. The round white rooted *turnep*. 2. The round blackiſh rooted *turnep*. 3. The round green rooted *turnep*. 4. The round red rooted *turnep*. 5. The round rooted *turnep*, yellow both on the outſide and within. 6. The long rooted manured *turnep*. *Tourn.* Inſt. p. 228. See the article TURNEP.

RAPAX, in ichthyology, a name given by Schoneveldt to the *corvus piſcis* of ſome writers, a ſpecies of chub or cyprinus, called *rappe* by the Germans, and by Geſner and others *capito fluviatilis rapax*. See the article CYPRINUS.

Broom RAPE. See OROBANCHE.

RAPHA, in anatomy, the ridge or line which runs along the under ſide of the penis, and reaching from the frænum to the anus, divides the ſcrotum and perinæum in two.

This line is not uſually cut in the grand operation of cutting for the ſtone, becauſe it is both harder than the reſt of the ſkin thereabouts, and alſo becauſe you muſt then cut upon the interſtices of the muſcles, which will make the re-union the more difficult.

RAPHANIS, in botany, the name by which the Attics, among the Greeks, called the radiſh; for the word *raphanos raphanus* with them, does not expreſs the radiſh, but the cabbage. The Greeks, of all other places, concurred in calling the radiſh *raphanos* and the cabbage *crambe*; and it is owing to this, that we have many authors who confound together theſe two plants, though ſo very unlike one another in appearance and uſe. It is generally to be underſtood, that wherever Theophraſtus mentions the word *raphanos*, he means by it the cabbage; and the ſame being obſerved, in regard to all the other Attic writers, the whole danger of confuſion and error will ceaſe.

A moderate knowledge either in the language or the ſubject might have prevented errors on this occaſion; yet Pliny, in his account of the radiſh, has been miſled by the word *raphanos* in Theophraſtus, which is that author's name for the cabbage, and has tranſlated all his account of the cabbage, and given it as part of the hiſtory of the radiſh. Theophraſtus ſays, that the Greeks diſtinguiſhed three kinds of the cabbage; the ſmooth leaved, the curled leaved, or criſp cabbage, and the wild cabbage: and Pliny has tranſlated this verbatim, and made it a part of his hiſtory of the radiſh. To this he has added ſome accounts from the Latin writers of their *raphanus*, which is the common radiſh; and putting theſe together, he has compoſed an account wholly unintelligible to all, but thoſe who ſee through the occaſion of the error. The virtues of the radiſh he has alſo intermingled with thoſe of the cabbage, interſperſing among the accounts he took from the Latin authors of the *raphanus*, the virtues and qualities of Theophraſtus's *raphanos*, that is the cabbage. The opinion of the cabbage and the vine being enemies to one another, and not growing any where together, is as old as Theophraſtus, and has a place in his account of that plant; but Pliny has perplexed the caſe, by tranſlating this quality as belonging to the radiſh, which no other author ever gave it; though ſcarce any, who have read the antients, have omitted it in the hiſtory of the cabbage.

RAPHANISTRUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of four leaves, placed in the manner of a croſs. The piſtil ariſes from the cup, and is at length made a long pod, jointed in ſeveral places, and reſembling a faſciated column, and containing roundiſh ſeeds, one lodged in every joint of the pod. See Tab. 1. of Botany, Claſs 5.

The ſpecies of *raphaniſtrum*, enumerated by Mr. Tournefort, are theſe. 1. The common *raphaniſtrum*, with ſmooth, larger,

larger, and fmaller jointed pods. 2. The *raphaniftrum* with white ftriated flowers, and fmall articulated ftriated pods. 3. The white flowered field *raphaniftrum*. 4. The yellow flowered field *raphaniftrum*; and 5. The *raphaniftrum* with the largeft ftriated and articulated pods. *Tourn.* Inft. p. 230.

RAPHANUS, *radifh*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of four leaves, difpofed in form of a crofs. The piftil arifes from the cup, and becomes at length a long horn-like pod, very thick and fpungy, and filled with two rows of roundifh feeds, feparated by a very thin intermediate membrane.

The fpecies of *radifh*, enumerated by Mr. Tournefort, are thefe. 1. The great orbicular or round *radifh*. 2. The white flowered great orbicular or round *radifh*. 3. The black *radifh*. 4. The fmaller or common garden *radifh*. *Tourn.* Inft. p. 229.

The Athenians expreffed the cabbage by the word ῥαφανος, *raphanus*, but all the other Greeks called the *radifh* by that name. Pliny not obferving this has run into ftrange errors. See the article RAPHANIS.

RAPISTRUM, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of four leaves, and is of the cruciform kind; and the piftil which arifes from the cup, finally becomes an unicapfular hufk of a fomewhat globofe figure, which contains a fingle feed.

The fpecies of *rapiftrum*, enumerated by Mr. Tournefort, are thefe. 1. The fingle feeded *rapiftrum* of Cafpar Bauhine. 2. The greateft round leaved fingle feeded *rapiftrum* of Cornutus; and 3. The field *rapiftrum*, with pointed, auriculated leaves. *Tourn.* Inft. p. 211.

RAPPE, in zoology, a name given by fome to the *capito fluviatilis* rapax of Gefner, more frequently known by the name of the *corvus pifcis*. *Willughby*'s Hift. Pifc. p. 256. See the article CORVUS *pifcis*.

RAPUNCULUS, *rampion*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of only one leaf, and is of the bell fhape, but very wide open at the mouth, and fo deeply divided into fegments, that it appears a ftar fafhioned one. The piftil is divided into two horns, and the cup afterwards becomes a membranous feed veffel, divided into three cells, and containing a number of very fmall feeds.

The fpecies of this plant, enumerated by Mr. Tournefort, are thefe. 1. The blue fpiked *rampion*. 2. The deep violet coloured flowered *rampion* with fpotted leaves. 3. The white flowered fpotted *rampion*. 4. The yellow flowered fpiked garden *rampion*. 5. The round headed long leaved *rampion*. 6. The Cretic pyramidal *rampion*, called by many authors *petromerula*. 7. The alpine horned *rampion*. 8. The grafs leaved *rampion*. 9. The fcabious headed blue flowered *rampion*, called by fome *fheeps fcabious*. 10. The white flowered fcabious headed *rampion*. *Tourn.* Inft. p. 113.

RAPUNTIUM, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of a tubular form, fulcated, and divided into feveral long and narrow fegments, in the manner of fingers. The piftil is enclofed in the cup, which afterwards becomes a dry fruit, divided into three cells, and containing numerous, and ufually very fmall feeds affixed to a placenta divided into three parts.

The fpecies of *rapuntium* enumerated by Mr. Tournefort are thefe. 1. The great fpiked fcarlet flowered *rapuntium*, called the red cardinal flower. 2. The great fcarlet American *rapuntium* with white lines in the flowers. 3. The blue flowered American *rapuntium*. 4. The white flowered American *rapuntium*. 5. The golden red leaved American *rapuntium* with a fmall blueifh flower. 6. The talleft American *rapuntium* with Cirfium leaves and greenifh flowers. 7. The fhining Cirfium leaved American *rapuntium* with double fcarlet conglobated flowers. 8. The purple flowered American *rapuntium* with throatwort leaves. 9. The fmall violet coloured burning *rapuntium*. 10. The purplifh blue burning *rapuntium*. 11. The white flowered burning *rapuntium*. 12. The leffer narrow leaved African *rapuntium* with violet coloured flowers. 13. The pinafter leaved Æthiopian *rapuntium* with hooded, violet coloured flowers. 14. The coronopus leaved Æthiopian *rapuntium* with hooded blue flowers. 15. The blue hooded flowered Æthiopian *rapuntium* with dentated leaves. 16. The low Canada *rapuntium* with toad flax leaves. *Tourn.* Inft. p. 163.

RARUM, *non-fpiffum*, in the antient mufic. See the article APYCNON, ἀπυκνον.

RASA, a word ufed by fome authors to exprefs refin of any kind. See RESIN.

RASAKETI, a name given by fome of the chemifts to *æs uftum*, or burnt copper.

RASCETA, a word ufed by the Arabian phyficians to exprefs the wrift or ankle.

RASE, *rafarium*, in our old writers, feems to have been a meafure of corn now difufed: toll fhall be taken by the *rafe*, and not by the heap or cantel. *Ordin. for bakers*, &c. c. 4. Pat. 12 Ed. 3. *Blount*.

RASE, in the manege. To *rafe* or glance upon the ground, called in French *razer le tapis*, is to gallop near the ground, as our Englifh horfes do.

RASILIS *ærugo*, in the materia medica of the antients, one of their kinds of verdigreafe. It was prepared in the following manner: they fet fome fharp vinegar over the fire in a ftrong earthen veffel, and covered it with a brafs pot inverted, well cleaned, and without any vent hole. And after fome time the veffels were to be feparated, and the verdigreafe which was found concreted on the infide of the brafs pot, was fcraped off, and put up for ufe.

RASPBERRY, in botany, the Englifh name of a fpecies of *rubus*. See the article RUBUS.

The *rafpberry* bufh is often found wild in fome of our northern counties, but is cultivated in gardens throughout England for the delicacy of its fruit. We have three kinds common about London. 1. The common. 2. The late red; and, 3. The white *rafpberry*.

Thefe fhrubs fend up great plenty of fuckers from their roots, and are very eafily propagated by them, they fhould be taken up in October, and before they are replanted their fibres fhould be fhortened; but the buds, which are at a fmall diftance from the ftem of the plant, muft not be cut off, becaufe thefe produce new fhoots the next fummer. They fhould be planted two feet afunder, and fet in rows, which fhould be five feet diftant from one another. The foil they thrive in beft is in a frefh fandy loam, which fhould neither be too moift nor over dry. The time for dreffing them is in October, when all the old wood which produced fruit the preceding fummer fhould be cut down to the ground, and the young fhoots fhortened to about two feet in length. The fpaces between the rows fhould then alfo be dug up, and fome other rotten dung buried in them. In the fummer they muft be kept clean from weeds, and once in three or four years there fhould be new beds made, and the old ones deftroyed, for they feldom bear well after that time. *Miller*'s Gardeners Dict.

RASPECON, in ichthyology, a name given by fome to the uranofcope or ftargazer. It is properly a fpecies of the trachinus; and is diftinguifhed by Artedi, under the name of the trachinus, with feveral cirri or beards growing from the lower jaw. See TRACHINUS.

RASSE *coronde*, in natural hiftory, a name given by the Ceylonefe to a peculiarly fine kind of cinnamon, which is the bark of a tree, growing no where but in that ifland. The name they give it fignifies fharp or biting cinnamon. This choice kind is exported annually, in confiderable quantity, by the Dutch Eaft-India company, who prohibit the mixing any other kind of cinnamon with it under a very fevere penalty. Phil. Tranf. N° 409.

RASTIS, a word ufed by fome chemical writers as a name for tin. See TIN.

RASTOL, or RASOES, a name given by fome of the chemical writers to copper.

RASTUL, a word ufed by fome of the chemical writers to exprefs falt in general.

RASURA; a word ufed by the pharmaceutic writers, to exprefs the fhaving woods, or other hard fubftances, to make them readily yield their virtues by decoction. Phyficians alfo ufe it to exprefs the corrofion of acrid humours.

RAT, in zoology. See the article MUS.

RAT, in the fea language, is ufed to exprefs a part of the fea, where there are rapid and dangerous currents, or counter currents.

RAT-*goofe*, in zoology, the name of a fmall fpecies of wild *goofe*, common in fome of the northern counties of England. See the article GOOSE.

Mufk RAT. See MUSK.

RAT-*tails*, or ARRESTS, in the manege, fignify callous hard fwellings upon the hinder legs under the hough, running along the finew. See the article ARRESTS.

RAT-*tailed*. A horfe is thus called that has no hair upon his tail. See HORSE.

RAT-*tailed worms*, in natural hiftory, a fpecies of fly-*worms*, with long tails, refembling thofe of *rats*, whence they have their name. They are of feveral fizes, and found alfo in different places, but all change into two winged flies, having very much the refemblance of bees, and commonly called bee flies. See Tab. of Infects, N° 49. and *Reaumur*'s Hift. Inf. Vol. 4. p. 439. See the article DRONE-*fly*.

RATIO (*Cycl.*)—When a *ratio* is given, expreffed in large numbers, it is often very ufeful to find an approximated value of it, in fmaller numbers. Mr. Huygens and Dr. Wallis have given methods for this purpofe, but that of Mr. Cotes, being the moft convenient in practice, we fhall here infert it. Suppofe the *ratio* 2,718281828495 to 1, or of 1 to 0,367879441171 were propofed to be reduced to fmaller terms, fo that no lefs numbers fhall exprefs it nearer. The operation may be as follows:

Ratios greater than the true.		*Ratios* less than the true.	
1	0×2	0	1
2	1	2	0
3	1×2	2	1×1
8	3	6	2
11	4×1	8	3×1
76	28	11	4
87	32×1	19	7×4
106	39	87	32
193	71×6	106	39×1
1264	465	1158	426
1457	536×1	1264	465×1
21768	8008	1457	536
23225	8544×1	2721	1001×8
25946	9545	23225	8544
49171	18089×10	25946	9545×1
&c.	&c.	&c.	&c.

Divide the greater term 2.71828, &c. by the lesser 1, or the greater 1 by the lesser 0,367879, &c. and again the lesser by the remainder, and this again by the last remainder, and so on: the quotients arising will be 2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1, 12, 1, 1, 14, 1, 1, 16, 1, 1, &c. These being found, two rows or columns of *ratios* must be made, the one containing the *ratios* greater than the true, and the other such as are less; beginning the computation from the *ratio's* 1 to 0, 0 to 1, which are most remote from the truth, and from thence proceeding to such as approach continually nearer. Let then the terms 1 and 0 be multiplied by the first quotient 2, and write the products 2 and 0, under the terms 0 and 1; then adding, there will arise the *ratio* 2+0 to 0+1, or 2 to 1. Multiply the terms of this *ratio* by the second quotient 1, and add the products 2 and 1 to the terms 1 and 0 in the first column, there will arise the *ratio* 2+1 to 1+0 or 3 to 1. The terms of this *ratio* being multiplied by the third quotient 2, and the products 6 and 2 added to the terms 2 and 1 of the second column, will give the *ratio* 8 to 3. These multiplied by the fourth quotient 1, and the products 8 and 3 added to the preceding terms 3 and 1 in the first column, will give the *ratio* 11 to 4. Whose terms multiplied by the fifth quotient 1, and the products 11 and 4 added to the *ratio* 8 to 3 give the *ratio* 19 to 7; whose terms being multiplied by the sixth quotient 4, and the products 76 and 28 being added to 11 and 4, give the *ratio* 87 to 32. And thus we may go as far as we think fit; proceeding alternately from one column to the other. This being done, we shall find *ratios* greater than the true, to be 3 to 1, 11 to 4, 87 to 32, 193 to 71, 1457 to 536, 23225 to 8544, 49171 to 18089, &c. And the *ratios* less than the true will be, 2 to 1, 8 to 3, 19 to 7, 106 to 39, 1264 to 465, 2721 to 1001, 25946 to 9545, &c. And these are the principal and primary *ratios*, which continually approximate to the *ratio* proposed.

But if the whole series of *ratios* greater than the true, be required, so that no *ratios* greater than the true, and expressed in smaller terms, shall come nearer the truth; and if also the whole series of *ratios* less than the true, and such, as that no *ratios* less than the true, and expressed in smaller terms, shall approach nearer to the truth, be desired, then other secondary *ratios* must be inserted between the primary already found. And these take place where the quotients surpass unity. They may be found by changing the multiplication by the quotient as above directed, into a continual addition of the terms, as often as there are units in the quotient. Thus, the first quotient being 2, the terms 1 and 0 are to be twice added to the terms 0 and 1. The sums will give the *ratios* 1 to 1 and 2 to 1. These last terms 2 and 1, the second quotient being 1, must be once added to the terms 1 and 0, and the sum will give the *ratio* 3 to 1. Also the terms 3 and 1, the third quotient being 2, are to be twice added to the terms 2 and 1; and the sums will give the *ratios* 5 to 2, 8 to 3. These last terms 8 and 3, the fourth quotient being 1 must be once added to the terms 3 and 1, and the sums will give the *ratio* 11 to 4. These terms 11 and 4, the fifth quotient being 1, must be once added to the terms 8 and 3, and the sums will give the *ratio* 19 to 7. Lastly, these terms 19 and 7, the sixth quotient being 4 must be four times added to the terms 11 and 4. The sums will give the *ratios* 30 to 11, 49 to 18, 68 to 25, 87 to 32. And so we may proceed as far as we think fit. The operation being performed, we shall find the whole series of *ratios* greater than the truth to be 1 to 0, 3 to 1, 11 to 4, 30 to 11, 49 to 18, 68 to 25, 87 to 32, &c. and in like manner, the whole series of *ratios* less than the truth will be 0 to 1, 1 to 1, 5 to 2, 8 to 3, 19 to 7, &c.

Example of the operation.

Ratios greater than the true.		*Ratios* less than the true.	
1	0×2	0	1
2	1	1	0
3	1×2	1	1
8	3	1	0
11	4×	2	1×1
19	7	3	1
30	11	5	2
19	7	3	1
49	18	8	3×1
19	7	11	4
68	25	19	7×4
19	7	87	32
87	32×1	106	39×1
&c.	&c.	&c.	&c.

See *Cotes* harmonia mensurarum, p. 7, &c.

The ingenious author has not given the demonstration of his method; but Dr. Saunderson has shewn the reason of it, in the fifth book of his algebra, to which we refer the reader.

By means of this method, the approximated values of the *ratio* of the circumference, to the diameter of a circle, may be found in small terms. Thus the proportion of the circumference of a circle to its diameter, being according to Van Ceulen's numbers, when abridged, 314159265359 to 100000000000; dividing the greater by the lesser, &c. as before directed, we shall find the quotients 3, 7, 15 and 1, which will give the following *ratios*, 3 to 1, 22 to 7, 333 to 106, and 355 to 113; the second is that of Archimedes, and the fourth that of Adrian Metius.

This proportion of 113 to 355 approaches very near the truth, only erring by 2 in the seventh decimal, when reduced to that form, for 355 : 113 :: 3, 1415129 : 1 now it ought to be 3,1415927 to 1. To remember this proportion the better, we may make use of the following artifice. Take the three first odd numbers 1, 3, 5, and write each twice, thus 113355, then will the three first figures of this number 113, be the diameter, and the three last, 355 the circumference. These approximations are of use in many practical parts of mathematics. See instances thereof in Huygen's *descriptio automati planetarii* among his posthumous works, tom. 2. p. 174. Edit. Amst. 1728, where he describes his method, and demonstrates it. In music, it is the foundation of the different schemes of geometrical temperatures. See the article TEMPERAMENT.

RATIO *modularis*. See LOGARITHM.

RATIONIS *os*, a term used by some anatomical writers to express the *os sincipitis*.

RATIONARIUM, among the Romans, a book which contained the accounts of the empire. *Pitisc*. Lex. Ant. in voc. It was otherwise called *breviarium*. See BREVIARY.

RATSBANE. See the article ARSENIC.

RATTLE *snake*, a very dreadful species of serpent, whose bite is fatal, if not timely remedied, and which is distinguished from all other serpents by the *rattles* in its tail. This is composed of several scaly substances, and is said to encrease by the creature's age; every year adding one scale to it. It moves over the rocks and mountains with prodigious swiftness, but is less nimble on even ground, than many other snakes.

It grows to four or five feet long, and sometimes, though rarely, more; and one of more than four feet long, having been dissected, and accurately described by Dr. Tyson, the account that gentleman gives of it may not be unacceptable to the reader. The body where largest, which was near the middle, measured six inches and a half round. Its neck only three inches. Its head was flat, as that of the viper; and as the jaws are very broad and protuberant, and the nose sharp, it somewhat resembles the head of an arrow. At the end of the nose are placed the nostrils, and between these and the eyes there are two other holes which may be mistaken for ears; but they only go into a hollow of the bone of the skull, without any perforation into the brain. The viper has nothing of these holes. The eyes are round, and wholly resemble those of the viper. The whole body of the creature greatly also resembles the viper, but for the singularity of the *rattle*; and over the eyes there are two large scales, looking like eye-brows.

The scales which cover the head are very small, thence they become gradually larger as they reach toward the middle of

of the body, and from the middle to the tail they grow lefs and lefs again; and all in fhape much refemble the broad and flat feeds of the common garden parfnip. There is fome variety in the colours of this creature, whether according to the difference of age or fex, or from leffer accidents. The moft ufual colours are thefe: the fcales are of a dufky greenifh, like the feathers of the back of the green-finch, and are variegated with fmall black fpots in great number; there alfo are four large ones of the fame colour. *Ray's* Syn. An. p. 291. *Tyfon's* Nat. Crotaph.

The back is of a mixt colour, of a dead yellowifh brown, variegated with blotches of black and yellow, and with a number of fmall dots of the fame colours; the larger blotches being laid in great regularity, and making a very beautiful teffelated figure; the fcales become darker as they approach the tail, where they are almoft black; and thofe on the ridge of the back, all along, are raifed into a fort of fharp prominence in their middle, like the fcales of a crocodile; thofe on the fides are plain and flat. The belly is all along covered with oblong parallellogram fcales, laid tranfverfely; thefe are very bright and gloffy, and are yellow, fpotted with black.

The head is fmall, in proportion to the body, but the mouth is capable of opening to a prodigious width. The tongue is wholly like that of the viper, compofed of two oblong portions, joined toward the bafes, but feparate as they approach the end. The teeth are of two kinds, the fmaller ones defigned for its eating with, the larger and longer for biting and poifoning what it feizes. Thefe are only placed in the upper jaw, but all the teeth of the mouth are of the canine kind, as the creature, never chewing its prey, has no ufe for dentes molares, or grinders.

The poifonous teeth are fituated on the outfide of the jaw, in the anterior part of the mouth; not fixed in the fockets of the jaws, as the others, but fixed to two bones. Thefe, in their natural ftate, are not vifible, even when the creature's mouth is opened, unlefs it be with an intent to wound; for they lie back under a membranaceous covering, and the creature has a power of erecting, and wounding with them at pleafure, as the lion and cat kind can retract, or thruft out their claws. Thefe teeth are crooked, and have a hollow at their bottom, and at their point a very plain and evident flit, looking like the neb of a writing pen. The teeth are hollow all the way from this flit to their bottom, and on preffing the gums in a dead *rattle-fnake*, the poifonous juice may be feen to afcend by degrees up the tooth, and at length to be difcharged out of the flit at the point. This makes it very plain in what manner the poifon is conveyed into the flefh, when the creature bites.

The *rattle* is affixed to the laft vertebra of the tail, and is compofed of a feries of fmall bones; that next the tail is ufually of a blueifh grey colour, the reft of a pale brown. Thefe bones are hollow, very thin, hard, and dry, and of a brittle texture, and very fonorous. They are all of the fame figure, reprefenting, in fome degree, the os facrum in the human fceleton, and all are nearly of the fame fize. The laft of thefe is feen to have a rigid extremity, in manner of a tail, and all the others have the fame, though it is not diftinguifhable in them, as in the joining it runs under two others; and by means of this ftructure they are all moveable with the fmalleft force, and the found is the more vigorous, as each of thefe tails ftrikes on two of the hollow joints, when put in motion.

The age of the creature is known by the number of joints of this *rattle*, which are found to be from one to twenty, or more. The ufe of this feems not to the creature, but to other animals, that they may be alarmed at the approach of fo terrible an enemy, and get out of its way in time. Pifo, and fome others, affirm, that this *rattle* put up a man's fundament, is as fatal a thing as the creature's bite. The power of doing mifchief, which nature has allotted to this animal, feems not only by its bite, but, according to the joint accounts of almoft all authors, it appears to have a power of deftroying even by a look. *Ray's* Syn. Anim. p. 322.

The charming, or fafcination of the *rattle-fnake*, as this is ufually called, has exercifed the wits of many naturalifts in vain, and many have difbelieved the fact. Sir Hans Sloan mitigates the matter, by fuppofing the creature firft to feize or bite its prey, which it then fuffers to efcape, as far as the poifon will let it, watching its death, that it may devour it without trouble; and that it is in this poifoned ftate that people have feen the fquirrels, &c. dancing about before the *rattle-fnake*, and dying convulfed; all which they have attributed to the power of charming in the eye of the *fnake*, not conceiving that it was the effect of the creature's having before bitten them. This, though a very plaufible account, yet however wants experience to confirm it, and the general teftimony of people, who have feen the facts, makes againft it.

The fame author gives us, however, from Colonel Beverley, the whole procefs of the charm. The colonel acquaints us, that fome company he was with once faw a hare, about half grown, fiting quietly in an orchard, and ftriking at her, fhe only removed a few yards; when wondering at the caufe, they faw a *rattle-fnake*, at about ten feet diftance, eying the hare as his deftined prey. The poor creature was, by this time, in agonies and convulfions, often getting up on its legs, as if intending to run away, but always immediately falling down again, and growing worfe and worfe, foon loft the ufe of its hinder legs, and panting vehemently, fell on its fide. In about half an hour more the hare feemed to have done with all ftruggles, and to be dead, on which the *fnake* uncoiled itfelf, and moved gently towards it, but the poor hare ftarting again, he ftopt; but when all was again quiet, he moved up to it, and, raifing his head, looked all over his prey; his colours looking at that inftant more beautiful than before, and his eyes fparkling. The hinder part of the hare had been toward the *fnake* all this time, and it had perifhed without much looking at its enemy. The *fnake* wetted the body all over with his flaver; and then, with great difficulty, taking firft the head into his mouth, fwallowed that, and afterwards the whole body, fucking it gently down, and not getting in the fhoulders without great difficulty.

It is certain, upon the whole, that there is much in this account to favour Sir Hans Sloan's opinion of the hare's having been firft bitten, though that was not feen, fince the convulfions, and lofs of the ufe of the hinder legs, feem a very natural effect of poifon; but we are affured, by perfons who have been eye-witneffes to the fact, that a bird hopping about in all this agony and terror, has, on the frightning the *rattle-fnake* away, flown off without any difficulty; fo that the whole feems yet not underftood. *Sloan's* Hift. Jamaica. *Beverley's* Virginia.

RAUCA *avis*, in zoology, the name of a bird defcribed by Nieremberg, as common about the lakes and rivers of America, and of the king-fifher kind, but nearly as large as a duck, and black on the crown, and white on the breaft and belly. Its neck is naturally very long in proportion to its body, yet it can occafionally contract and fhorten it in a very wonderful manner. It is a native of Mexico, and is efteemed very good for the table. Mr. Ray has placed this among the birds, the accounts of which he is diftruftful of. *Ray's* Ornitholog. p. 300.

RAUCEDO, *hoarfenefs*, in medicine, the name of a difeafe which confifts in the conftriction of the glandulous coat, and other glandular parts, near the top of the wind-pipe, by means of which the due quantity of lymph, deftined to lubricate the wind-pipe, is not fuffered to flow to its place. This diftemper differs in degree, being milder when from external caufes, and greatly more obftinate and troublefome when from internal.

Signs of it. The *hoarfenefs* of the voice in fpeaking fufficiently manifefts this complaint, but it is ufually alfo attended with a flight cough in the milder kind; and when of the feverer fort, is not unfrequently accompanied with catarrhal and fcorbutic effects; and not uncommonly, in its worft ftates, with a complication of venereal taints. The perfons moft fubject to *hoarfeneffes* are young and middle-aged men, and fometimes women, who have for fome time been afflicted with obftructions of the menfes.

Caufes of it. The general caufe of an *hoarfenefs* is an interception of the lymph deftined to lubricate the wind-pipe; and the occafional caufe of this is ufually an obftruction of the glandular parts, toward the top of that organ, in the fimple *raucedo*; but in the complicated kind, in which there is a fcorbutic or venereal taint, an erofion of the epiglottis is very often the caufe. Befide thefe, there are many accidental and external caufes, which will bring on a *hoarfenefs*; fuch as the falling of any fmall particle of extraneous matter, if it be only a grain of duft, into the windpipe; a vehement cough will alfo bring it on, as will a frequent loud fpeaking, and too fat foods, and acrid or bilious humors ftagnating about thefe parts. It is eafy to conceive, that the more complicated this difeafe is, the more difficult will be the cure; and accordingly *hoarfeneffes*, which have fcorbutic or venereal taints for their bafis, are with great difficulty removed.

Method of cure. Lubricating medicines are firft to be given, to obtund the acrimony of the humors, and relax the frictures of the glandular parts. To this purpofe are properly taken oil of almonds, and the pectoral fyrups, with barley water, mucilaginous broths, and decoctions of the pectoral herbs, or infufions of them drank in the manner of tea. When there is a coryza, or cough attending it, thefe are to be treated in the ufual way, and the *hoarfenefs* will ufually go off with them. When acrid and bilious humors are in the cafe, the abforbents and nitrous medicines are to be given, with gentle diaphoretics; powders compofed of crabs eyes, nitre, and diaphoretic antimony, are of great ufe in this cafe. The bowels, in all thefe cafes, are to be kept gently relaxed; and where there is a fcorbutic, or venereal taint for the bafis, thofe difeafes muft be attacked in the common way, and then the *hoarfenefs* will be regularly taken off. A relaxation of the wind-pipe is ufually accufed as being the caufe of a *hoarfenefs*, and that not without

ſome foundation; ſince where the humors are collected, there will be ſuch a relaxation; but when we conſider all the circumſtances of the diſeaſe, and obſerve that relaxing medicines are the only cure for it, we muſt acknowledge, that though a relaxation of ſome part of the aſpera arteria may be in the caſe, yet that the origin of the complaint is from a conſtriction of ſome part of it; and it appears, that the longer this complaint remains with people, the greater the conſtriction becomes; ſo that after a courſe of years, the voice is not only *hoarſe*, but is in a manner ſuppreſſed ſo, that it can ſcarce be heard. *Junker*'s Conſp. Med. p. 505.

RAVEL *bread*, a ſort of *bread*, called alſo *blackwhytlof*, as being of a middle fineneſs betwixt white and brown.

RAVEN, *corvus*, in ornithology. See CORVUS.

It is rare to find this creature white, yet it happens ſometimes. Boyle[a] mentions one. There was alſo one ſhewn to the Royal Society not long ago.—[[a] Works Abr. Vol. 2. p. 46.]

Night RAVEN, an Engliſh name for a heron which flies in the night, and makes a very odd and hoarſe noiſe. It has been applied by ſome to the bittern, or *ardea ſtellaris*, but improperly, belonging of right to the *ardea cinerea minor*, or ſmaller grey heron, called *nycticorax*. *Ray*'s Ornithol. See NYCTICORAX.

RAVIS, the ſame with *raucedo*. See RAUCEDO.

RAUTY *mummy*, or RAUTY *muddum*, *ſtone mummy*, a name given by the people of the Eaſt-Indies to a kind of foſſile ſubſtance, much valued for its medicinal virtues. It is of the nature of the ſelenites, and is found upon the high rocks, and ſuppoſed to be generated of the dew which falls from the heavens; but this is an idle opinion, and the formation of it is evidently the ſame with that of the European rhomboidal ſelinites. They beat it to powder, and after boiling it in milk, they give it in caſes of the venereal kind. In a common clap, they give half a ſcruple night and morning. *Woodward*'s Cat. Foſſ. Vol. 2. p. 9.

RAY, *raia*, in ichthyology. See RAIA.

RAY, in our old writers, a word appropriated to cloth never coloured, or dyed. 11 Hen. IV. c. 6. *Blount*, *Cowel*.

RAY (*Cycl.*)—RAY *of curvature*, in geometry, is uſed to ſignify the ſemi-diameter of the circle of curvature. See CURVATURE, *Appendix*.

RAYCHE, in ichthyology. See RAYTE, infra.

RAYTE, or RYCHE, in ichthyology, a name given by Joannes Cuba, Albertus, and others, to the common ſkaite, or ſkaire. See the article RAIA.

RAZE, in the manege. A horſe is ſaid to have *razed*, whoſe corner teeth ceaſe to be hollow; ſo that the cavity, where the black mark was, is filled up; that is, even, ſmooth, and *razed*, or ſhaven, as it were, and the mark diſappears. See the articles TEETH and MARK.

RAZOR *bill*, in zoology, the common Engliſh name of the alka, a web-footed bird with no hinder toes, common on our ſea ſhores. See ALKA.

RAZOR-*fiſh*. See the article DACTYLUS.

REAR (*Cycl.*)—REAR *half files*, in the military art. See FILE *leaders*.

REAR *up*, in the manege, called in French *cabrer*, is ſaid of a horſe that riſes upon his hinder legs, as if he would come quite over.

REARED, or *Wale*-REARED. See WALE-*reared*.

REBUS, (*Cycl.*) a word uſed by the chemical writers ſometimes to ſignify ſour milk, and ſometimes for what they call the ultimate matter, of which all bodies are compoſed.

RECEIVER (*Cycl.*)—It is to be obſerved, that a very ſmall crack in the *receiver*, uſed in pneumatical experiments, does not render them uſeleſs; for, upon evacuating the internal air, the external preſſing the glaſs on all ſides, brings the edges of the glaſs cloſer together. But in caſe of conſiderable flaws, a plaſter may be applied, made of quick lime, finely powdered, and nimbly ground, with a proper quantity of the ſcrapings of cheeſe, and water enough to bring the mixture to a ſoft paſte; which, when the ingredients are well incorporated, will have a ſtrong and fetid ſcent; and then it muſt be immediately ſpread upon a linnen cloth, and applied, leſt it begin to harden. *Boyle*'s Works Abr. Vol. 2. p. 417.

RECEIVERS, in chemiſtry, veſſels of earth, glaſs, &c. for receiving any diſtilled liquor. See Tab. of Chemiſtry, N° 22, 23, and 34.

RECEPTACULUM (*Cycl.*)—RECEPTACULUM *ſeminum*, in botany, the name given by authors to the baſe of the flowers and ſeeds in the ſyngeneſiæ, or compound flowered plants. This is alſo called, by ſome writers, *thalamus floſculorum*. The flowers ſtand on this in conſiderable numbers, and without any pedicles. The diſk of the *receptacle* is of various ſhapes in the various plants; in ſome it is flat, in others concave, in others convex; in ſome globular, and in many pyramidal. Its ſurface is ſometimes naked, and ſometimes paleaceous. In thoſe plants, in which the ſurface is naked, it is either abſolutely ſmooth, or furniſhed with ſmall tubercles, or with a few hairs. In thoſe in which it is paleaceous, it is all over beſet with narrow pointed paleæ, which are erect, compreſſed, and ſtand between the flowers.

RECEPTARII, a term of reproach uſed to ſuch phyſicians as write pompous receits for loads of medicines, more conſulting the good of the apothecary than the patient; as alſo for ſuch as give receits for general medicines, to be uſed at the diſcretion of people wholly unacquainted with the nature of diſeaſes.

RECESSUS, (*Cycl.*) a word uſed by ſome medical writers to expreſs an abſceſs, or apoſthumation.

RECIMUS, among the Romans, a kind of ſquare mantle, or veil worn by women on their head. Salmaſius will have it to have been a ſort of gown uſed by the Roman ladies, and tucked up before with a ſquare pin, of a purple colour. *Danet*. in voc.

RECIPROCAL, (*Cycl.*) in mathematics, is applied to quantities, which multiplied together produce unity [a]. Thus $\frac{1}{x}$ and x, y and $\frac{1}{y}$ are *reciprocal* quantities. And $\frac{1}{x}$ is ſaid to be the *reciprocal* of x, which, *vice verſa*, is the *reciprocal* of $\frac{1}{x}$.—[[a] Maclaurin de Lin. Geom. propriet. general. p. 10.] See the Appendix to his Algebra.

RECITANTE. See FAVORITO.

RECLASSE, *auricula*, in botany. See AURICULA.

The characters of a good flower of this ſort are theſe. 1. The ſtem of the flower muſt be lofty and ſtrong. 2. The foot-ſtalk of the flower muſt be ſhort, that the umbel may be regular and cloſe. 3. The pipe, or neck of each flower ſhould be ſhort, and the flowers large and regularly ſpread, being no ways inclinable to cup. 4. The colours muſt be very bright, and well mixed. 5. The eye of the flower muſt be large and round, and of a good white or yellow, and the tube or neck muſt not be too wide.

Theſe are to be raiſed from ſeeds; to procure which the beſt flowers ſhould be made choice of, and theſe muſt be expoſed to the open air, and to ſhowers, that the ſeeds may be perfect. The time of their ripening is June, and they are known to be ripe by the ſeed veſſel becoming brown and opening. This ſeed may be ſown any time between Auguſt and Chriſtmas; and the beſt ſoil for it is good freſh light ſandy mould, mixed with very rotten cow dung, or tanners bark. With this the boxes or pots muſt be filled, and the ſeeds lightly ſcattered on it, and covered an inch deep with rotten willow mould. Cover the ſurface with nets, or otherwiſe, to preſerve the ſeed from birds, and give the boxes half the day's ſun. In March the young plants will appear, and they muſt then only have the morning ſun till ten o'clock. They muſt be carefully watered after this, a little at a time, and in July they will be ready to tranſplant. They muſt be ſet in the ſame ſort of earth, at three inches diſtance, and ſhaded carefully, till they have taken root. The ſpring following theſe young plants will flower, and then the fineſt of them ſhould be marked, and each removed into a pot of the ſame earth, in which they are to be kept till the next ſpring, when it will appear what they truly are.

The fine flowers, thus obtained, may afterwards be propagated from ſlips, or off-ſets taken from the old roots in April when they are in bloom; and theſe muſt be managed juſt as the young plants from ſeed, and the ſecond year will produce perfect flowers.

Theſe are the rules for the propagating theſe plants; but in order to have them flower in perfection, the following rules muſt alſo be obſerved.

1. The plants muſt be preſerved from too much wet in winter, and muſt have free air, and not too much ſun. 2. In the beginning of February, if the weather be mild, the earth in your *auricular* pots muſt be taken off as far as may be, without diſturbing the roots, and new freſh earth laid in its place. 3. The pots muſt be covered with matting in the night, to defend them from froſts while the plants are budding. 4. When the ſtalk begins to be long, they muſt be defended from haſty rains, yet not kept too much under cover, which draws up the ſtalk too long, and makes it weak; and they muſt be watered frequently, a little at a time, and none of the wet muſt be ſuffered to fall on the plant. Laſtly, when the flowers begin to open, the pots ſhould be removed to a ſtage of ſhelves, one over another, placed under cover, open to the morning ſun, but ſheltered from the midday's ſun. Here they may remain till their flowers are paſt, and then they muſt be ſet out to have the benefit of the rains and free air, for the ripening of the ſeed, which muſt be ſaved carefully, and ſpread on papers, and laid to dry. *Miller*'s Gardners Dict.

RECLINATE *ſtalk*. See the article STALK.

RECOGNITORS, *recognitores*. The jury impanelled upon an aſſize are called *recognitors*, becauſe they acknowledge a diſſeiſin by their verdict. *Bract*. lib. 5. *Cowel*.

RECOLATION, a method of fining the decoctions of vegetables, &c. by repeated percolation, or ſtraining them ſeveral times ſucceſſively through a linnen or woollen bag.

RECOMPOSITION, in chemiſtry, the compounding of bodies from their ſeparated parts, or principles, ſo as to compoſe

compose the original whole again. This is extremely difficult to effect universally, but in some cases it may be done, and that so perfectly, that the *recomposed* body shall not be distinguishable by the senses from that which never had been separated by the fire. If the art of chemistry were perfect, we should thus be able, at least in some degree, to *recompose* all the bodies we divide; but this is far from being the case at present. We can by no means do this in vegetable and animal bodies, where there is a vascular structure, and therefore we are carefully to distinguish between the regeneration of organized, and that of unorganized bodies. *Shaw*'s Lectures, p. 168.

RECONCILIATION *of penitents*, in church history. See PENITENTS, *Cycl.*

RECRUITS, in the military art, new men raised to supply the places of such as have lost their lives in the service, or are rendered unserviceable by age or wounds.

RECRUIT *horses*, are the *horses* brought up for compleating the regiments of horse or dragoons every year.

RECTIFICATION (*Cycl.*)—That the *rectification* of spirits may, in all cases, proceed with the greatest exactness, a due regard to it must be had even from the first fermenting the substance from which they are to be made, and continued through all the stages of distillation, the low wines, proof spirit, and alcohol. The management of the fermented liquor, to this purpose, is principally the letting it stand to subside after the fermentation is over, and the drawing it off clear and thin, not too rich for the still. The still is not to be overfilled with this. Great care must be taken to prevent its burning, and the faints that run last must be kept separate, not mixed with the rest of the liquor distilled, which is now called the low wines. In the *rectifying* these into proof spirit, great caution must be used that the fire be kept regular, not raised by sudden spirits, which always throw up the oil in large quantities, which is to be left behind. In the succeeding *rectification* of the proof spirit into alcohol, the same cautious management of the fire is necessary; and, in both this and the last, the faints are not to be suffered to run in among the spirit, but to be saved separate. They may be all mixed together at last, and reduced to a spirit fit for burning in lamps; but the keeping out of the *rectified* liquor will keep away the coarsest and most stinking part of the oil of the ingredients.

By these easy means, without any additional trouble or charge, we might be furnished with a spirit greatly exceeding what we commonly meet with. And in general, the art and mystery of our sellers of the several sorts of English brandies, seem to consist in this prudent management, and in the adding a little of the *oleum vini*, or oil of wine lees, to the spirits thus procured pure: this gives the flavour of foreign brandies, and is so extensive in its use, that half an ounce of it is sufficient for a hogshead of pure spirits.

Malt spirit is that which principally requires all this care in the *rectification*, because its oil is more nauseous and offensive than that of any other spirit; but all others will be greatly the better for being treated in the same manner, and it is indeed necessary that they should for some particular uses.

It is remarkable, that no one method of combinatory *rectification*; that is, of the *rectification* performed by means of salts, and other additions, is suited to all the several kinds of spirits, scarce indeed will any one way serve for any two spirits; but this method, by simple and careful distillation, is equally suited to all. Melasses spirit, cyder spirit, wine spirit, or brandy, rum, and arrack, are all improved by it, and all of them are then known to be perfectly *rectified*. When in the state of alcohol, they not only prove totally inflammable in a little vessel floating upon cold water, but when poured into the purest spring water, they have not the least power of making any change in it, nor leave any marks of oilyness, or that unctuosity, which, on the mixture of the less pure spirits, floats on the top, and in certain lights gives the rainbow colours. *Shaw*'s Essay on Distillery.

RECTIFYER, (*Cycl.*) in the distillery, the person whose employment it is to take the coarse malt spirit of the malt stiller, and re-destill it to a finer and better liquor. The art of the *rectifyer* might be entirely set aside, if the malt stiller could make his spirit perfect at a second operation; which seems very practicable, if the malt stillers could be got to forsake their old track. The great things to be recommended for the improvement of their art, would be first the brewing in perfection, and secondly the keeping their wash after the manner of stale beer, till it has entirely lost its malt flavour, and required a pungent acid vinosity; and then thirdly leaving out the lees, to distil with a well regulated fire. It is scarce to be thought how pure a spirit is to be obtained from malt this way; but the great art would be, the finding a way to make malt liquors artificially stale, bright, and flavourless, though otherwise vinous. *Shaw*'s Lectures, p. 223.

RECTUS (*Cycl.*)—RECTI *abdominis*. These are long narrow muscles, thicker than the oblique; they lie near each other, like two large bands from the lower part of the thorax to the os pubis, the linea alba coming between them. Their breadth diminishes, and their thickness increases gradually from above downward. The superior extremity of each of these muscles is fixed to a part of the lower extremity of the sternum, to the three lowest true ribs, and to the first false rib, by the same number of digitations, of which that which is farthest from the sternum is the broadest.

The body of the muscle lies in the vagina formed by the aponeurosis of the broad muscles of the abdomen: exteriorly it is divided into several portions, resembling distinct muscles placed end-wise, by transverse tendons termed enervations, which commonly are all above the umbilicus, very seldom below it, and adhere very closely to the vagina. These insertions are pretty irregular: they do not always penetrate the whole thickness of the muscle; and, in that case, they do not at all appear, or but very little, on the inner surface. Sometimes those which are seen on the surface do not run quite cross the whole breadth of the muscle.

The lower extremity of this muscle ends in a thin tendon, fixed in the internal labium of the upper edge of the os pubis near the symphysis, and there it touches the tendon of the other *rectus*. Above the umbilicus, these muscles are at some distance from each other, according to the breadth of the linea alba, but below it they come nearer the linea alba, being there narrower, and near their lower extremity, that line is almost entirely hid by their thick edges. *Winslow*'s Anatomy, p. 168.

RECTUS *anterior*, a muscle called also *gracilis anterior*, as long as the os femoris, and lying directly along the foreside of the thigh. The greatest part of it is fleshy, and its middle is broader than the two extremities. It has its name *rectus* from the strait diameter in which it lies, and its other *gracilis* from its thinness and flatness. It terminates above by a pretty strong tendon, which is divided into two branches, one short and strait, the other long and bent; the short branch running up in a strait line, is inserted in the anterior inferior-spine of the os ilium. The long branch is inflected backward over the supercilium of the acetabulum, and runs in the direction of it from the spine, toward the great ischiatic sinus: it is strong and flat, adhering very closely to the bone, and covered by the orbicular ligament and the glutæus minimus; and, according to the common method of dissecting, is therefore usually cut off, and the small branch of the tendon only left observable. From hence the muscle runs down wholly fleshy, and partly penniform, some of its fibres meeting above and separating below. It is narrow at the upper extremity, and grows gradually broader towards the middle, afterwards contracting in the same manner, and at the lower extremity of the os femoris, ending in a flat tendon. Through its whole course it lies between the two vasti, and covers the crureus; and its inferior tendon is inserted in the upper edge of the patella, from whence it sends down a small plane of tendinous fibres, which adhere very closely to the convex side of that bone, and having reached the great ligament seem to be lost therein. *Winslow*'s Anatomy, p. 212.

RECTUS *musculus*, in anatomy, a name given by Fabricius, in his treatise of the eyes, to the muscle, which serves to elevate the upper eye-lid, called by Cowper and others *aperiens palpebram*, and by Albinus *levator palpebræ superioris*.

RECTUS *internus major*, in anatomy, a name given by Winslow to one of the muscles of the head, described by Fallopius, under the name of the *musculus nonus capitis*; and by Winslow, the *musculus rectus anterior longus*.

RECTUS *capitis major*, a small, flat, short muscle, broad at the upper part, and narrow at the lower, and situated obliquely between the occiput and second vertebra of the neck. It is fixed below the branch of the bifurcated spine of the second vertebra of the neck, at a tuberosity, which is often found at the upper part of the branch; from thence it ascends a little obliquely outward, and is inserted in the posterior part of the inferior transverse line of the os occipitis, at a small distance from the crista, being a little covered by the obliquus superior. *Winslow*'s Anatomy, p. 236.

RECTUS *minor capitis*, this muscle has a small insertion below in the posterior eminence of the first vertebra; from thence it ascends laterally, and is inserted immediately under the posterior part of the inferior transverse line of the os occipitis, in a superficial fossula on one side of the crista occipitalis. Ibid. p. 237.

RECTUS *capitis anticus brevis*, a small flat muscle, about the breadth of one finger, situated laterally on the part of the body of the first vertebra. It is fixed below to the basis or root of the transverse apophysis of that vertebra, near the anterior eminence; from thence it runs obliquely upward, and inward, to a transverse impression in the lower side of the apophysis basilaris of the occipital bone immediately before the condyle on the same side, being covered by the anticus longus. Ibid.

RECTUS *capitis anticus longus*, a muscle in some degree of a pyramidal figure, lying along the anterior and lateral parts of the vertebræ of the neck, all the way up to the basis cranii. It is fixed to the anterior parts of the transverse apophysis,

apophyses, of the third, fourth, fifth, and sixth vertebræ in a digitated manner, from thence it runs up obliquely inwards, and towards the lateral parts of the bodies of the vertebræ, passes on the foreside of the first and second, without being inserted in them, and approaching gradually toward the same muscle, on the other side, it is inserted near it in the fore part of the lower side of the apophysis basilaris. Id. Ibid.

Rectus *capitis posticus major*, in anatomy, a name given by Albinus, in his history of the muscles, to a muscle called *magnus rectus capitis* by Winslow, and described by Vesalius by the name of the *tertius capitis moventium*; and by Spigelius, and others, under that of *rectus major*.

Rectus *capitis posticus minor*, a name given by Albinus to a muscle of the head, called by Riolanus and others *posticus minor*, and by Winslow *rectus parvus*; Vesalius has described it under the name of *quartus caput moventium*.

Rectus *exterior oculi*, in anatomy, a name given by Fabricius and others to one of the muscles of the eye, called by Riolan and others the *superbus*, and by some the *elevator oculi*; it is the *abductor* of Albinus, one of his *quatuor recti*.

Rectus *inferior oculi*, in anatomy, a name given by Fabricius, and some others, to one of the muscles of the eye, called by others *humilis*, and by Albinus the *depressor*. It is one of the *quatuor recti oculi* of that author.

Rectus *interior oculi*, in anatomy, a name given by Fabricius to one of the muscles of the eye, called by Molinet the *bibitorius*; and by Cowper, Albinus, and others, the *adductor oculi*. See Adductor, *Cycl.* and *Suppl.*

Rectus *superior oculi*, in anatomy, a name given by Fabricius to one of the muscles of the eye, called the *attollens* by Albinus, and by others the *elevator oculi* and the *superbus*. See the article Elevator *oculi*.

RECUPERATORES, among the Romans, were commissioners, appointed to take cognizance of private matters in dispute, between the subjects of the state and foreigners, and to take care that the former had justice done them.

It came at last to be used for commissioners, to whom the prætor referred the determination of any affair between one subject and another. *Pitisc.* in voc.

RECURVIROSTRA, in zoology, the name of a very remarkable bird, so called from the remarkable bending upwards of its beak, and named *avosetta* by the Italians.

It is a little larger than the common lapwing, weighing usually about ten ounces; its beak is three fingers breadth long, very slender, black, and flatted, and bending upwards, which is peculiar to it alone. Its head is moderately large and very round, and both that and the upper part of the neck is black, only that there is a small variegation of grey just behind the head. Its breast, belly, and throat are all of a snowy whiteness, and its back is variegated with black and white; its wings are also variegated with black and white; its tail is all white; its legs very long and blueish, and feathered half way down below the knees. It is very common in Italy, and is not unfrequently seen about the eastern shores of England. *Ray's* Ornithol. p. 241.

RED (*Cycl.*)—To make a deep *red* in glass, the following method is that most practised by the glass-men. Take crystal fritt twenty pounds, broken pieces of white glass one pound, calcined tin two pound, mix these well together, and put them into a pot to melt and purify; when these are melted, take steel calcined, scales of iron from the smith's anvil, both powdered very fine, of each an equal quantity; put leisurely an ounce of this mixed powder to the before-mentioned metal, mix all well together, and let them stand six or eight hours in fusion, to incorporate; take out a proof after this, and if there be too little of the powder, it will appear of a dusky yellow; then more of the powder must be added, and then add three quarters of an ounce of calcined brass ground to a fine powder; mix them thoroughly together, and the mass will be of a blood *red*; continue stirring the whole together, and frequently taking out proofs of the colour; when it is right, work it immediately, otherwise it will lose its colour and become black. The mouth of the pot must in this process be left open, else the colour will be lost. *Neri's* Art of Glass, p. 100.

Blown red, in the porcelain manufacture, a name given to a peculiarly coloured china ware of a spangled *red*, or to the colour alone that spangles it. It is an ornament easily introduced into use in our own manufactories of porcelain ware, and is done in the following manner. The colour is to be prepared of common copperas, calcined to a *red* colour in a charcoal fire, in a crucible, with another luted on the top of it inverted, and with a hole in its bottom. The signal of the calcination being finished, is, when the black clouds cease to come up through the hole, and a fine white thin vapour arises in their place. The vessels are to be then suffered to cool, and the *red* matter in them is to be reduced to a fine powder; while the vessels to be coloured with this are yet wet. The operator is to provide a glass pipe, and covering one end of it with a piece of fine gawse; he is to dip this into the powder, and taking it carefully out, with what little is sticking to it, he is to blow against the vessel at some distance from it: thus the finest part of the powder only will reach the vessel, and will be laid on in form of glittering spangles, very small, but all distinct. This is a sort of colouring much esteemed by the Chinese themselves, and they have a way of using the common blue in the same manner; but few of the vessels, thus painted, come over to us. Observ. de l'Asie.

Red *game*, an English name of a bird, common in the mountainous parts of Yorkshire, and some other of our northern counties. It is of the shape of a partridge, but much larger, and of a mixed colour of red and black, and is feathered down to the ends of the toes. See the article Gor-*cock*.

Indian Red, a name used by the colourmen and painters for a kind of purple ochre, brought from the island of Ormus in the Persian gulf, and used as a red colour. It is called among the authors on these subjects *terra persica*. *Hill's* Hist. of Foss. p. 58.

Red *land*, in agriculture, a term much used by husbandmen, to express a sandy soil of a reddish hue, interspersed for the most part with pieces of sand stone of the same colour, or somewhat deeper.

There are several varieties of this soil, one of which is almost entirely made up of sand; another with an admixture of clay with the sand, the whole making a loose loamy earth; and a third, full of fragments, of a poor sandy iron ore, and often containing shining specks of selenitæ. *Moreton's* Northamp. p. 40.

Red-*lead*. See the article Minium.

Red-*shank*, in zoology, the name of a water bird, called by authors *gallinula erythropus*, and *callidrys*. It is about the size of the common plover. The back is of a greyish or brownish green, usually spotted with black; its neck grey, and its throat variegated with black and white; the breast is white, with a few loose streaks of black. The wing feathers are variegated with black, brown, and white; the breast is two fingers breadth long, slender, and shaped like the beak of the woodcock; reddish at the base, and blackish lower down. Its legs are of a fine beautiful red, and the hinder toe is very short and small. *Ray's* Ornithol. p. 221.

Red *start*, in zoology, the English name of the *ruticilla*, a very beautiful bird, with a white spot on his head and a red tail. See the article Ruticilla.

Red *weed*, in botany, a name given to a plant common in Bermudas, and some other places; and called by our first travellers to that part of the world the *summer island redweed*. Its berry is of a fine red colour, and affords a tincture little inferior to that of cochineal, and possessing all its virtues in medicine; the only misfortune of this, and some other very fine vegetable colours, is, that they fade soon. The juice of the fruit of the opuntia, or prickly pear, is as fine a dye as can be procured from the cochineal, but it will not stand; the insect feeding on this, however, we find affords a colour of the same nature, that will stand. The fruit of the *red weed* is in the same manner liable to be eaten by insects as that of the prickly pear, and it is worthy a trial, whether its colour obtained at second hand from those insects, will not stand as well as the cochineal does, and whether the insects may not be propagated in a sufficient abundance to serve the markets in the same manner. Phil. Transf. N°40.

Red *wing*, in zoology, the name of a bird of the turdus, or thrush kind, called also in some places the *wind thrush*, or *swine pipe*, and by authors the *turdus iliacus*, or *tylas*.

It is a little smaller than the common thrush, and is less spotted. Its back, neck, and head are of the same colour with those of the common thrush; but its sides, under the wings, and the feathers which line the wings, are of an orange colour, or dusky red; its belly and breast are whitish, and its throat yellowish, with brown spots: the wings are of a sort of chesnut colour, a little variegated. It feeds on insects, as worms, and the like; and is a bird of passage, coming to us at the same time with the fieldfare, and leaving us also when that bird does. It is not well known where they breed, though some have guessed it to be in the mountains of Germany and Bohemia. They have a bitterish taste, and are less valued than the fieldfare. *Ray's* Ornithol. p. 139.

REDDLE, (*Cycl.*) the common English name for the substance, called in Latin *rubrica*, and used in painting, and for marking sheep, &c. *Hill's* Hist. of Foss. p. 48. See the article Rubrica.

REDIMICULUM, among the Romans, a girdle, which going about the neck, divided on the breast, and passing down each side, went round, and kept the robe tight to the body. See *Pitisc.* in voc.

REDUCTION, (*Cycl.*) in metallurgy, is the bringing back metalline substances, which have been changed into *scoriæ* or ashes, or otherwise divested of their metallic form, into their natural and original state of metals again. *Cramer's* Art of Assaying, p. 185.

All metals and semi-metals may be reduced by proper management, whatever have been their changes, except only zink, which having been burnt to ashes, admits of no *reduction*. But the mixture of gold, and silver, was never yet

yet radically diſſolved by any experiment, whatever ſome may have imagined. Even ſome earths will turn into metals by the admixture, and intimate union of a phlogiſton, or inflammable principle; but theſe metals never need any ſuch principle to aſſiſt their *reduction*. Ibid. p. 186.

REDUNDANT (*Cycl.*)—REDUNDANT *interval*, in muſic, is uſed for an interval exceeding the truth by a comma. See INTERVAL.

Some apply *redundant* to an interval exceeding a diatonic interval by a ſemitone minor; but this is more uſually called a ſuperfluous interval. See the articles SECOND, *Cycl.* and, INTERVAL, *Suppl.*

REDUVIA, in medicine, a word uſed by ſome for a whitlow, and by others for a painful crack, or other diſorder about the nails, either of the fingers or toes.

REED, *arundo*, in botany. See ARUNDO.

REED, *calamus*, likewiſe denotes a ſort of meaſure, otherwiſe called *canna*. See CANNA.

REED *ſparrow*, the Engliſh name of a bird by many eſteemed of the picus, or wood-pecker kind, having ſhort legs, and climbing up *reeds*, &c. as the other upon trees; but it wants the great character of that genus of birds, having its toes placed only one behind, and three before, as in the generality of other birds. There are two ſpecies of this bird, a greater and a leſſer; the firſt called by authors *junco*, and *cinclus*, and the other *cannevarola*, and by ſome *paſſer arundinaceus minor*. *Ray*'s Ornitholog. p. 99. See the articles JUNCO and CANNEVAROLA.

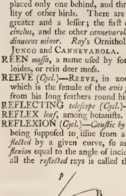
REEN *moſſa*, a name uſed by ſome for the mountain coralloides, or rein deer moſs.

REEVE (*Cycl.*)—REEVE, in zoology, the name of a bird which is the female of the *avis pugnax*; the male of which, from his long feathers round his neck, is called the *ruffe*.

REFLECTING *teleſcope* (*Cycl.*)—See TELESCOPE.

REFLEX *leaf*, among botaniſts. See LEAF.

REFLEXION (*Cycl.*)—*Cauſtic by* REFLEXION. Rays of light being ſuppoſed to iſſue from a given point, and to be *reflected* by a given curve, ſo as to make the angle of *reflexion* equal to the angle of incidence; a curve that touches all the *reflected* rays is called the *cauſtic by reflexion*.



Thus, let S be the given point from whence the rays iſſue, S L any incident ray, P L p the tangent at L, L C the radius of curvature at L, L m the *reflected* ray conſtituting the angle C L m, equal to C L S; then if the *reflected* rays always touch the curve $h\,m\,e$, it is the cauſtic by *reflexion*.

Again, let S P, perpendicular to the tangent L P, meet it always in P, a point of the curve D P; let H M E be the curve, by the evolution of which D P is deſcribed, and let P M touch H M E in M; join S M, and produce it to m, ſo that S m be equal to 2 S M: then will m be a point in the cauſtic of the curve B L, when S is the radiating point.

Hence, if perpendiculars be always drawn from the radiating point to the tangents of the *reflecting* curve, and a new curve be ſuppoſed to be the locus of the interſections of the perpendiculars and tangents, then will the evoluta of that new curve be ſimilar, and ſimilarly ſituated to the cauſtic by *reflexion* of the propoſed *reflecting* curve. See *Mac Laurin*'s Fluxions, Art. 409.

The point m may be thus found. Let C R be perpendicular to L R, the *reflected* ray, and let $L s = L S$; then if L R be biſected in q, $q\,m$ will be a third proportional to $q\,s$ and q R; that is, $q s : q R :: q R : q m$, or $s q \times q m = \overline{qR}^2 = \overline{qL}^2$. Id. Art. 410.

Mr. de l'*Hopital*, in his Analyſe des Inf. Petits, Sect. 6. has treated of cauſtics by *reflexion*.

Point of REFLEXION, in geometry. See POINT *of reflexion*.

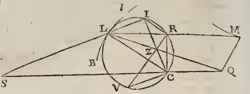
REFRACTED (*Cycl.*)—REFRACTED *angle*, in optics, the angle contained between the *refracted* ray and the perpendicular.

REFRACTION (*Cycl.*)—REFRACTION *to the perpendicular*, in optics, is when a ray falls from a leſs denſe into a more denſe medium, and ſo approaches nearer the perpendicular.

REFRACTION *from the perpendicular*, in optics, is when a ray falling inclined from a more denſe medium into one leſs denſe, in breaking departs further from the perpendicular.

Cauſtics by REFRACTION. When rays of light, iſſuing from a given point, are *refracted* at any curve, ſo that the ſine of the angle contained by the *refracted* ray, and the perpendicular to the curve, is always to the ſine of the angle contained by the incident ray, and that perpendicular, in one conſtant ratio, the curve that touches all the *refracted* rays, is called the *cauſtic by refraction*.

Let S be the radiating point, S L any incident ray on the curve B L l, L R the *refracted* ray, C the center of the curvature at L, C I perpendicular on the incident ray in I, C R perpendicular to the *refracted* ray in R; join S C



and I R; let R Z, perpendicular to R I, meet C I in Z; join L Z, meeting S C in Q; and let Q M, parallel to R Z, meet the *refracted* ray L R in M; then will the point M be in the cauſtic. See *Mac Laurin*'s Fluxions, Art. 413.

The point M may alſo be determined, by deſcribing a circle L I R C on the diameter L C, and by drawing V C parallel to S L; then applying R C in this circle, ſo that it may be to C I, in the given ratio of the ſine of *refraction*, to the ſine of incidence, joining V R, that meets C I perpendicular from C to the incident ray in Z, joining L Z that meets S C in Q, and drawing Q M parallel to V R. When L Z is parallel to S C, the *refracted* ray is the aſſymptot to the cauſtic. Ib. Art. 414.

The Marquis de l'Hopital has treated of *cauſtics by refraction*, in his Anal. des Inf. Pet. Sect. 7.

REFRANGIBLE, whatever is capable of being refracted. See REFRANGIBILITY, *Cycl.*

REFRIGERATORY, (*Cycl.*) a term uſed for a veſſel of cold water, through which the worm of the alembic paſſes in the common method of diſtillation, by means of which the vapours are condenſed. It is alſo uſed for the bucket head of the common ſmall alembic, containing water for the ſame purpoſe.

REFUTATION, *refutatio*, in rhetoric, that part of the anſwer made to an opponent, which diſproves what had been advanced by him. *Voſſ.* Rhet. l. 5. p. 382.

REGENERATED *tartar*. See TARTARUS *regeneratus*.

REGERENDARIUS, among the Romans, an officer who ſubſcribed and kept a regiſter of all petitions preſented to the præfect. *Pitiſc.* in voc.

REGESTOLA, in zoology, a name uſed by ſome authors for the mattageſs, or larger butcher bird, a very ſmall hawk, not exceeding the ſize of a common thruſh, but very fierce and voracious. *Aldrovand*, de Avib. See MATTAGESS and LANIUS.

REGIMEN, (*Cycl.*) in medicine, a regulation of diet, with intent to reſtore, or to preſerve health. In chemiſtry, it ſignifies the due regulation of fire.

REGINA *aurarum*, in zoology, a name given by Nieremberg to a bird called by the Mexicans *cozeacoauhtli*. It has obtained its name from its being able to fly againſt the ſtrongeſt winds. It is of the bigneſs of an eagle, and its whole body is of a blackiſh purple, variegated with a browniſh yellow, and a deep black. Its wings are variegated with black, yellow, and grey. Its legs are red. Its claws very ſtrong and ſharp; and its beak like that of the parrot. It has ſome rugoſe ſkin on the forehead, and about the beak, and its tail is black above, and grey underneath. It feeds on ſnakes, rats, and other vermin, but will alſo eat human dung. It flies very high. It is a native of Mexico, and breeds in ſpring. Its feathers are ſaid to be a remedy for many diſeaſes. But the truth of this account is much to be doubted. *Ray*'s Ornitholog. p. 302.

REGION (*Cycl.*)—REGIONS *of the ſea*. As the naturaliſts, in their deſcriptions of the ſubterranean parts of the globe, diſtinguiſh the earth into three regions of different depths, in which different temperatures are obſerved; ſo in deſcribing the ſea, they allow it two regions; the one extending from the ſurface of the water, down ſo low as the rays of the ſun can pierce, and extend their influence; and the other, from the loweſt bounds of that to the bottom. It is eaſy to ſee, that theſe regions rather regard quality than ſpace, and that their boundaries are far from being regular, or equal in all places, and at all times. The places expoſed to the hotteſt ſunſhine will have the largeſt upper *region*; thoſe where the ſun has leaſt power, will have the ſmalleſt; and the ſame part of the ſea will have its upper *region* more or leſs deep, according to the ſeaſon of the year. This upper *region* of the ſea is always more or leſs hot; the lower *region*, except in ſome few particular places, is every where cold; and the water, where the upper *region* is large, is always remarkably ſtill and quiet in the lower. *Boyle* of Coſmical Qualities.

Subterranean REGION. The earth is not only divided on its ſurface into *regions* and countries, but philoſophers, who have had occaſion to diſcourſe of its inner parts, have alſo divided them into three diſtinct *regions*, according to their different depths from the ſurface. The temperature of the ſubterranean parts of the globe is diſtinguiſhed according to the diviſion of theſe *regions*, but is not ſo regular and

preciſe

precise as some have supposed. The first *region* of the earth is very variable, both as to bounds and temperature. The second *region* seems for the most part cold, in comparison of the other two; but in several places, which, by reason of their distance from the surface of the earth, it would be natural to call the middle *region*, the temperature of the air is very different at the same seasons of the year, which shews that it depends on something more than bare depth from the surface. The third *region* of the earth is universally observed to be warm, but by no means regularly, or uniformly: the same depth in some places, giving only a moderate warmth, while in others it gives a very considerable heat. Borrichius tells us of a certain abbe fond of chemistry, and particularly curious in the matter of long digestions by regular heat, who found a way of making a furnace perpetually warm, by piercing the earth to a certain depth, and using the heat of this third *region* of it. His method, we are told, was to bore a hole with a pike twenty feet deep, and pour into it ten or twelve pounds of quicksilver; this made its way into the strata, and through them in a body into the chambers of heat in this third *region*, where the heat having a vent upwards, made by this opening, never failed to ascend in a perpetual and regular stream, and gave that regular digesting heat that no artificial fire could equal. But this is an alchemical story. *Boyle* of Cosmical Qualities. *Borrich.* de Ortu Chem.

REGION, in antient Rome, a part or division of the city. They were only four in number till Augustus's time, who divided the city into fourteen *regions*, over each of which he settled two surveyors, called *curatores viarum*, who were made annually, and took their divisions by lot. These fourteen *regions* contained 424 streets, 31 of which were called great or royal streets, which begun at the gilt pillar that stood at the entry into the open place in the middle of the city.

The extent of these divisions varied greatly, some being from 12000 or 13000 to 33000 feet and upwards in circumference. Authors, however, are not agreed as to the exact limits of each. See *Kenn.* Rom. Antiq. Not. l. 1. c. 2. p. 34. seq. *Pitisc.* Lex. Antiq. in voc. *regio*. *Danet*, Dict. in voc. *Pancirol.* Descript. Urb. Rom. T. 3. p. 283.

REGRADATION, *regradatio*. See DEGRADATION, *Cycl.*

REGULAR *leap*, in music. See LEAP.

REGULUS (*Cycl.*)—The separation of silver out of the *regulus*, made from the silver ore by means of lead, is to be performed in this manner. Put two coppels of the same bigness, perfectly dry, and capable of containing at least one third more than the *regulus*, under a muffle in an assay-furnace; make a strong fire, and let them be red hot for a quarter of an hour, then free the *regulus* from its scoriæ, by striking it gently with a hammer, and put it carefully into one of the hot coppels, and into the other put, at the same time, the same quantity of granulated lead alone, as was used in the making the *regulus*. When the *regulus* boils and smoaks diminish the fire a little, and let the coppels be kept moderately, but not violently red hot. When it has stood so long, that the skin of litharge, continually produced from the lead, and covering the surface of the *regulus*, disappears, and the coppel shews the scoriæ only of the lead with the pure silver, either in fusion, or hard and bright in the middle, let the coppel continue only a minute or two longer on the fire; then take it out with a pair of tongs, take away the metal in grains, and if any scoriæ, or fragment of the coppel adhere to it, wrap it together in a paper, and squeeze it between the cheeks of a vice, or a pair of tongs, to break off that brittle matter without hurting the *regulus*. If this *regulus* be pure silver, it will now be very white, but if it contain any gold, it will shew it by its yellowness.

To determine exactly how much silver the quantity of ore contained, weigh it nicely in a fine balance, and take out the small *reguline* lumps from the other coppel, and weighing that, deduct its weight from that of the other, because so much silver that owes to the lead used in making it, and the remainder is the proportion of silver contained in the ore. *Cramer's* Art of Assaying, p. 211.

REGULUS *cristatus*, the *crested* or *golden crown wren*, the name of a very beautiful little bird, the smallest of all the European birds. Its whole weight is not more than a dram, and the crown of its head is adorned with a very beautiful saffron coloured, or orange red spot, which is called its crest, and by some its crown, and from this golden crown the bird has obtained the name of the *regulus*, *tyrannus*, *basilcus*, and other appellations of royalty.

This crown the bird can at pleasure draw together, by wrinkling its forehead, and by this means hide it from sight. The edges of this crown are of a pale yellow, and its end circumscribed by a black line. It is of an oblong figure, and is extended strait from the origin of the beak to the back part of the head. The sides of this little bird's neck are of an extremely glossy greenish yellow, and the ambit of its eyes white. Its neck and back are of an obscure yellowish green, and its breast of a dusky white, sometimes of a pale greenish cast. Its wing feathers are brown, with their edges yellowish without, and whitish within; and the middle ones are so tinged in part with black, that when they are folded in the shutting of the wing, they make a black spot in its middle; and the tips of one series of the feathers being white, they make also a white transverse streak on each wing. The tail is brownish, the feet yellow, and the beak half an inch long, and very slender and black. They are common about the Peak in Derbyshire, and in some other parts of England. They sit usually on the tops of oaks, and other high trees. They lay six or seven eggs, not larger than peas. *Ray's* Ornitholog. p. 163.

REGULUS *non cristatus*, in zoology, the name of a bird more commonly known by the name *luteola*, and by some called *asilus*. *Ray's* Ornitholog. p. 164. See LUTEOLA.

REJECTIO, a word used by medical authors for the casting any thing up preternaturally by the mouth, whether it be by vomiting or by spitting.

REINS (*Cycl.*)—REINS, in the manege, a name given by the Duke of Newcastle to two straps, or ropes of a cavesson, which he ordered to be made fast to the girths, or the pommel of the saddle, with intent that the rider should pull them with his hand, in order to bend and supple the neck of the horse.

False REIN is a lath of leather passed sometimes through the banquet, to bend the horse's neck, which is disapproved of by the Duke of Newcastle; by reason it slacks the curb, and makes the bit no more than a trench that has no curb.

REIS *effendi*, in the Turkish affairs, an officer of state answering to our chancellor.

RELAIS, in fortification, a French term, the same with *berme*. See BERME, *Cycl.*

RELATION, *relatio*, in rhetoric, is sometimes used to signify the same with recrimination. See RECRIMINATION, *Cycl.*

REMANCIPATION, *remancipatio*, among the Romans, a form of divorce observed in marriages that had been contracted by *coemption*. This was done by delivering the wife into the husband's hands; so the marriage was dissolved by the husband's redelivering the wife into any person's hands, agreed upon between them. *Pitisc.* in voc. See COEMPTION.

REMISSION (*Cycl.*)—REMISSION, *remissio*, ανεσις, in the antient music, was used to signify the passage of the voice from acute to grave; being opposite to intention. *Aristoxen.* p. 10—13. *Aristid.* Quint. p. 8, 9.

REMOLADE, or CHARGE, in the manege. See the article CHARGE, *Cycl.*

REMORA (*Cycl.*)—This is a small oblong fish, whose body is of a cylindric figure, and tapers off to a thinness at the tail. Its mouth is triangular, and the upper part is shorter than its under. Its head is flat, and marked with streaks, so as to look like the palates of some fishes: these run transversely, and are carried on to the back, making a striated substance of two fingers breadth, by which it fastens itself to any other substance, as the body of a larger fish, the hulk of a ship, or the like. The eyes are small and yellow, with a black pupil. It has no teeth, but in their places a multitude of small prominences. It has two fins under the gills, and two more lower on the body. Beside these it has two longitudinal fins, one on the back, the other on the belly, running the length of the body to the tail. The whole fish is of a greyish colour, and it is caught in the East and West Indies, and in many other seas. See Tab. of Fishes, Nº 14. and *Marcgrave's* Hist. Bras. p. 117.

REMORA *mutiani*, in natural history, a name given by some to the genus of shells called *concha venerea*, and *porcellana*. See PORCELLANA.

REMOTION, *remotio*, in rhetoric, the same with what is otherwise called *metastasis*. See METASTASIS.

REMOULIN, in the manege, is used to denote a star upon a horse's forehead.

REMPHAN, in antiquity, the Egyptian name for the planet Saturn. Some think that *remphan* was the moon. See the article CHIUN.

REMURIA, among the Romans, a festival instituted in honour of Remus by his brother Romulus. Mem. Acad. Inscr. Vol. 1. p. 45.

RENALIS *lapis*, in natural history, the name given by many authors to a sort of siderochitum, or crustated ferrugineous body of that kind, containing a nucleus of a different matter from that of the crusts. It is found about Prague, and in some other places, lying near the surface in strata of a yellow clay. Its usual bigness is that of a ripe peach, and its crusts are of a dusky ferrugineous brown colour; and its internal nucleus of a pale yellowish green, composed of a marley earth, and usually of a kidney-like shape, whence its name.

RENDS, in a ship, are the same as the seams between her planks.

RENES (*Cycl.*)—RENES *succenturiati*. Valsalva has endeavoured to prove the *renes succenturiati*, or *glandulæ renales*, to be organs of generation, or assistant to them. Valsalva claimed this discovery. Mr. Ranby suspected that the duct which

which the Italian journals mentioned, as the principal part of this discovery, was no other than an artery sent off from that of the capsula on each side, to the testicles of men, and ovaria of women. Morgagni explained Valsalva's doctrine more fully. Valsalva gives the following reasons for his opinion. He observes the seminary vessels of several fowls to come out from these capsulæ, before they are sent from the testicles. In the viper and water tortoise, he remarks such membranous connections between the *renes succenturiati*, and testicles, as make it probable that such excretories are sent through the capsulæ to the testicles. He affirms, his having seen vessels, which were neither nervous, sanguiferous, or lymphatic, going from the human capsulæ to the testicles. His observations are much the same as to females. To these he subjoins the consent and sympathy observed between the loins and genital parts. To confirm all, he cut away one testicle, and extirpated the *kidney* of the opposite side, of a whelp. The wounds healed, but the creature was of a very lax habit, and so far from attempting coition, that he did not seem fond of bitches when they were proud. Acad. Bonon. Comment. p. 376. & seq. See also Phil. Transf. N° 387. Sect. 3. where we have an inquiry into this discovery, made by Valsalva, of an excretory duct from the glandula renalis to the epididymis by Mr. John Ranby. And in N° 395. Sect. 12. there are mentioned, by the same gentleman, two newly discovered arteries in women going to the ovaria; which he thinks to be probably the same with what Valsalva took for excretory ducts of the glandulæ renales. Valsalva's discovery was first mentioned in the *giornale di leterati* of Venice for 1719, and inserted in the Phil. Transf. N° 385. Sect. 9.

RENETTE, in the manege, is an instrument of polished steel, with which they found a prick in a horse's foot.

RENIFORM *leaf*, among botanists. See LEAF.

RENTAL, a roll wherein the rents of a manor are written and set down, and by which the lord's bailiff collects the same: it distinguishes the lands and tenements, and the names of the tenants, the several *rents* arising, and for what time, usually a year. Comp. Court Keep. 475.

REPART, in the manege, is to put a horse on, or make him part a second time.

REPAND *leaf*, *repandum folium*, among botanists. See the article LEAF.

REPHON. See the article REMPHAN.

REPOLON, in the manege, is a demivolte, the croupe in, closed at five times. The Italians are mighty fond of this sort of manege. In making a demivolte, they ride their horses short, so as to embrace or take in less ground, and do not make way enough every time of the demivolte.

REPRISE, in the manege, is a lesson repeated, or a manege recommenced. Thus we say to give breath to a horse upon the four corners of the volte with only one *reprise*, that is, all with one breath.

REPROOF, *objurgatio*, in rhetoric, is distinguished from *invective*. See the article INVECTIVE.

REPRODUCTIVE *system of preservation*. See the article ANNIHILATION.

RERE *county*, a word used in the statutes of Westm. 2. c. 39. And 2 Ed. 3. c. 5. And seems by those statutes to be some public place, which the sheriffs appointed for the receiving of the king's money after his county court was done. *Terms of Law*. *Blount*.

REPUDIUM, among the Romans. See DIVORCE.

RESCUSSOR, in law, the party that commits a *rescous*. 2 Cro. 419. *Blount*.

RESEDA, *base rocket*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the polypetalous anomalous kind, consisting of several dissimilar petals; from the cup of which there arises a pistil, which finally becomes a membranaceous capsule usually of a trigonal form, or else square, though sometimes oblong and cylindric, and containing roundish seeds.

The species of *reseda* enumerated by Mr. Tournefort are these. 1. The common *reseda*. 2. The French *reseda* with curled leaves. 3. The broad leaved *reseda* with yellow flowers. 4. The white flowered *reseda* with leaves like the calcitrapa. 5. The common small *reseda*, called by many authors the phyteuma. 6. The common lesser *reseda* with leaves not so deeply cut. 7. The common whole or uncut leaved small *reseda*. *Tourn*, Inst. p. 423.

RESIANT *rolls*, are rolls wherein the *resiants* of a tithing, &c. are set down. Comp. Court Keep.

RESIDUARY *legatee*, is he to whom the *residuum*, or what remains of an estate, after funeral charges, debts, and legacies are paid, is left by will.

RESIN (*Cycl.*)—According to Theophrastus *resin* was obtained by stripping off the bark from pines, and by incisions made in the silver fir and the pitch pine. The inhabitants of mount Ida, he tells us, stripped the trunks of pines, on the sunny side two or three cubits from the ground. He observes, that a good pine might be made to yield *resin* every year, but the indifferent pines only every other year, and the weaker trees once in three years; and that three runnings were as much as a tree could bear. It is remarked by the same author, that a pine doth not at once produce fruit and *resin*; but the former only in its youth and the latter in its old age.

RESISTANCE (*Cycl.*)—RESISTANCE *of fluids*. The greatest part of authors have established it as a certain rule, that, whilst the same body moves in the same medium, it is always *resisted* in the duplicate proportion of its velocity; that is, if the *resisted* body move in one part of its track, with three times the velocity with which it moved in some other part, then its *resistance* to the greater velocity will be nine times the *resistance* to the lesser. If the velocity in one place be four times the velocity in another, the *resistance* to the greater velocity will be sixteen times the *resistance* to the lesser, and so on. This rule, though excessively erroneous, when taken in a general sense, is yet undoubtedly very near the truth, when confined within certain limits.

In order to conceive the *resistance of fluids* to a body moving in them, it is necessary to distinguish between those fluids which being compressed by some incumbent weight, perpetually close up the space deserted by the body in motion, without permitting, for an instant, any vacuity to remain behind it; and those fluids in which (they being not sufficiently compressed) the space left behind the moving body remains for some time empty. These differences, in the resisting fluids, will occasion very remarkable varieties in the laws of their *resistance*, and are absolutely necessary to be considered in the determination of the action of the air in shot and shells; for the air partakes of both these affections, according to the different velocities of the projected body.

If a fluid was so constituted, that all the particles composing it were at some distance from each other, and there was no action between them, then the *resistance* of a body moving therein, would be easily computed, from the quantity of motion communicated to these particles: for instance, if a cylinder moved in such a fluid in the direction of its axis, it would communicate to the particles it met with a velocity equal to its own, and in its own direction, supposing that neither the cylinder, nor the parts of the fluid were elastic; whence, if the velocity and diameter of the cylinder be known, and also the density of the fluid, there would thence be determined the quantity of motion communicated to the fluid, which (action and re-action being equal) is the same with the quantity lost by the cylinder, consequently the *resistance* would be hereby ascertained.

In this kind of discontinued fluid, the particles being detached from each other, every one of them can pursue its own motion in any direction, at least for some time, independent of the neighbouring ones; wherefore, if, instead of a cylinder, moving in the direction of its axis, a body, with a surface oblique to its direction, be supposed to move in such a fluid, the motion the parts of the fluid will hereby acquire, will not be in the direction of the *resisted* body, but perpendicular to its oblique surface; whence the *resistance* to such a body will not be estimated from the whole motion communicated to the particles of the fluid, but from that part of it only, which is in the direction of the *resisted* body. In fluids then, where the parts are thus discontinued from each other, the different obliquities of that surface, which goes foremost, will occasion considerable changes in the *resistance*; although the section of the solid, by a plain perpendicular to its direction, should in all cases be the same. And Sir Isaac Newton has particularly determined, that in a fluid thus constituted, the *resistance* of a globe is but half the *resistance* of a cylinder of the same diameter, moving in the direction of its axis with the same velocity.

But though the hypothesis of a *fluid*, thus constituted, be of great use in explaining the nature of *resistances*; yet, in reality, no such fluid does exist within our knowledge: all the *fluids* with which we are conversant are so formed, that their particles either lie contiguous to each other, or at least act on each other in the same manner, as if they did; consequently, in these fluids, no one particle, contiguous to the *resisted* body, can be moved, without moving at the same time a great number of others, some of which will be distant from it; and the motion thus communicated to a mass of the *fluid* will not be in any one determined direction, but will in each particle be different, according to the different manners in which it lies in contact with those, from which it receives its impulse; whence, great numbers of the particles, being diverted into oblique directions, the *resistance* of the moving body, which will depend on the quantity of motion communicated to the fluid in its own direction, will be hereby different in quantity, from what it would be in the preceding supposition, and its estimation becomes much more complicated and operose.

If the fluid be compressed by the incumbent weight of its upper parts (as all fluids are with us, except at their very surface) and if the velocity of the moving body be much less than that with which the parts of the fluid would rush into a void space, in consequence of their compression; it is evident, that in this case the space left by the moving body will be instantaneously filled up by the fluid; and the parts of the fluid, against which the foremost part of the body presses in its motion, will, instead of being impelled forwards in the direction

direction of the body; circulate, in some measure, towards the hinder part of the body, thereby to restore the equilibrium, which the constant influx of the *fluid* behind the body would otherwise destroy; whence the progressive motion of the fluid, and consequently the *resistance* of the body, which depends thereon, would be, in this instance, much less than in our first hypothesis, where each particle was supposed to acquire, from the stroke of the *resisting* body, a velocity equal to that, with which the body moved, and in the same direction. Sir Isaac Newton has determined, that the *resistance* to a cylinder, moving in the direction of its axis, in such a compressed fluid as we have here treated of, is but one fourth part of the *resistance*, which the same cylinder would undergo, if it moved with the same velocity, in a fluid, constituted in the manner we have described in our first hypothesis, each fluid being supposed to be of the same density.

But again, it is not only in the quantity of their *resistance* that these fluids differ, but likewise in the different manner, in which they act on solids of different forms moving in them. We have shewn, that in the discontinued fluid, which we first described, the obliquity of the foremost surface of the moving body would diminish the *resistance*; but in compressed fluids this holds not true, at least not in any considerable degree; for the principal *resistance* in compressed fluids arises from the greater or lesser facility, with which the fluid, impelled by the forepart of the body, can circulate towards its hindermost part; and this being little, if at all, affected by the form of the moving body, whether it be cylindrical, conical, or spherical, it follows, that while the transverse section of the body, and consequently the quantity of impelled fluid is the same, the change of figure in the body will scarcely affect the quantity of its *resistance*.

And this case, that is, the *resistance* of a compressed fluid to a solid, moving in it with a velocity much less than what the parts of the fluid would acquire from their compression; this case, I say, has been very fully considered by Sir Isaac Newton, who has ascertained the quantity of such a *resistance*, according to the different magnitudes of the moving body, and the density of the fluid. But he very expressly informs us, that the rules he has laid down are not generally true, but upon a supposition that the compression of the fluid be increased in the greater velocities of the moving body: however, some unskilful writers who have followed him, overlooking this caution, have applied his determinations to bodies moving with all kinds of velocities, without attending to the different compressions of the fluids they were *resisted* by; and by this means they have accounted the *resistance* of the air to musket and cannon-shot, to be but one third part of what it is found to be by experience.

Indeed, from all we have said, it appears plain enough, that the *resisting* power of the medium must be increased, when the *resisting* body moves so fast, that the fluid cannot instantaneously press in behind it, and fill the deserted space; for when this happens, the body will be deprived of the pressure of the fluid behind it; which in some measure balanced its *resistance*, and must support on its forepart the whole weight of a column of the fluid, independent of the motion it gives to the parts of the fluid; and besides, the motion in the particles driven before the body, is, in this case, less affected by the compression of the fluid, and consequently they are less deflected from the direction, in which they are impelled by the *resisted* surface; whence this species of *resistance* approaches more and more to that described in our first hypothesis, where each particle of the fluid being unconnected with the neighbouring ones, it pursued its own motion, in its own direction, without being interrupted or deflected by their contiguity; and therefore, as we before observed, that the *resistance* of a discontinued fluid to a cylinder, moving in the direction of its axis, was four times greater than the *resistance* of a fluid sufficiently compressed of the same density, it follows, that the *resistance* of a fluid, when a vacuity is left behind the moving body, may be near four times greater than that of the same fluid, when no such vacuity is formed; for when a void space is thus left, we have shewn the *resistance* to approach, in its nature, to that of a discontinued fluid.

This then may probably be the case in a cylinder moving in the same compressed fluid, according to the different degrees of its velocity; so that if it set out with a great velocity, and moves in the fluid till that velocity be much diminished, the resisting power of the medium may be near four times greater in the beginning of its motion than in the end. In a globe the difference will not be so great, because, on account of its oblique surface, its *resistance* in a discontinued medium, is but about twice as much as in one properly compressed; for its oblique surface diminishes its *resistance* in one case, and not in the other: however, as the compression of the medium, even when a vacuity is left behind the moving body, may yet confine the oblique motion of the parts of the fluid, which are driven before the body, and as in an elastic fluid (as is our air) there will be some degree of condensation in those parts; it is highly probable, that the *resistance* of a globe, moving in a compressed fluid with a very great velocity, will be between that of a globe and of a cylinder, in a discontinued medium; that is, (in proportion to its velocity) we may suppose it be more than twice, and less than four times the *resistance* of the same globe, moving slowly through the same medium; whence, perhaps, we shall not much err in supposing the globe in its swiftest motions to be resisted near three times more, in proportion to its velocity, than when it is slowest.

And as this increase of the *resisting* power of the medium will take place, when the velocity of the moving body is so great, that a perfect vacuity is left behind it, so some degree of augmentation will be sensible in velocities much short of this; for even when, by the compression of the fluid, the space left behind the body is instantaneously filled up; yet, if the velocity, with which the parts of the fluid rush in behind, is not much greater than that, with which the body moves; the same reasons we have urged above, in the case of an absolute vacuity, will hold in a less degree in this instance; and therefore we are not to suppose, that, in the increased *resistance*, which we have hitherto treated of, it immediately vanishes, when the compression of the fluid is just sufficient to prevent a vacuum behind the *resisted* body; but we must consider it as diminishing only, according as the velocity, with which the parts of the fluid follow the body, exceeds that with which the body moves.

Hence then we conclude, that if a globe sets out in a *resisting* medium, with a velocity much exceeding that with which the particles of the medium would rush into a void space, in consequence of their compression, so that a vacuum is necessarily left behind the globe in its motion; the *resistance* of this medium to the globe will be near three times greater, in proportion to its velocity, than what we are sure, from Sir Isaac Newton, would take place in a slower motion. We may further conclude, that the *resisting* power of the medium will gradually diminish, as the velocity of the globe decreases, till at last, when it moves with velocities which bear but a small proportion to that, with which the particles of the medium follow it, the *resistance* becomes the same with what is assigned by Sir Isaac Newton in the case of a compressed fluid.

And from this determination we may learn how false that position is, which asserts the resistance of any medium to be in the duplicate proportion of the velocity of the *resisted* body; for it plainly appears, by what we have said, that this can only be considered as nearly true in small variations of velocity, and can never be applied in the comparing together the *resistances* to all velocities whatever, without the most enormous errors. See new Principles of Gunnery, by Mr. *Robins*, Part 2. Prop. 1.

As to the *resistance* of the air, it has been thus determined from experiments. Mr. Robins, in his New Principle of Gunnery, pag. 74, 75, &c. having taken a musket barrel, and charging it successively with a leaden ball of three quarters of an inch diameter, and about half its weight of powder, and taking such precaution in weighing of the powder, and placing it, as to be sure, by many previous trials, that the velocity of the ball could not differ by 20 feet in 1′ from its medium quantity. It was fired against a pendulum (described under the head GUNNERY, *Append.*) placed at 25 feet, 75 feet, and at 125 feet distance from the mouth of the piece respectively. In the first case it impunged against the pendulum with a velocity of 1670 feet in 1′; in the second case with a velocity of 1550 feet in 1′; and in the third case with a velocity of 1425 feet in 1′; so that in passing through 50 feet of air, the bullet lost a velocity of about 120, or 125 feet in 1″; and the time of its passing through that space being about $\frac{1}{32}$, or $\frac{1}{30}$ of 1″, the medium quantity of *resistance* must, in these instances, have been about 120 times the weight of the ball; which, as the ball was nearly $\frac{1}{12}$ of a pound, amounts to about 10 lb. avoirdupoise.

Now if a computation be made, according to the me hod laid down for compressed fluids in the 38th Propos. of lib. 2. of Sir Isaac Newton's Principia, supposing the weight of water to be to the weight of air, as 850 to 1, it will be found that the *resistance* of a globe of three quarters of an inch diameter, moving with a velocity of about 1600 feet in 1″, will not, on those principles, amount to any more than a force of $4\frac{1}{6}$ lb. avoirdupoise; whence we may conclude (as the rules in that proposition for slow motions are very accurate) that the *resisting* power of the air in slow motions is less than in swift motions, in the ratio of $4\frac{1}{6}$ to 10, a proportion between that of 1 to 2, and 1 to 3.

Again, charging the same piece with equal quantities of powder, and balls of the same weight, and firing three times at the pendulum, placed at 25 feet distance from the mouth of the piece, the medium of the velocities with which the ball impinged was 1690 feet in 1″. Then removing the piece 175 feet from the pendulum, the velocity of the ball, at a medium of five shots, was 1300 feet in 1′. Whence the ball, in passing through 150 feet of air, lost a velocity of about 390 feet in 1′; and the *resistance*, computed

puted from these numbers, comes out something more than in the preceding instance, amounting to between 11 and 12 pounds avoirdupoise: whence, according to these experiments, the *resisting* power of the air to swift motions is greater than in slow ones, in a ratio which approaches nearer to the ratio of 3 to 1, than in the preceding experiments.

Next, to examine this *resistance* in smaller velocities, the pendulum being placed at 25 feet distance, was fired at five times, and the mean velocity with which the ball impinged was 1180 feet in 1″. Then removing the pendulum to the distance of 250 feet, the medium velocity of five shot at this distance, was 950 feet in 1″; whence the ball, in passing through 225 feet of air, lost a velocity of 230 feet in 1″, and as it passed through that interval in about $\frac{2}{11}$ of 1″, the *resistance* to the middle velocity will come out to be near $33\frac{1}{3}$ times the gravity of the ball, or 2 lb. 10 oz. avoirdupoise. Now the *resistance* to the same velocity, according to the laws observed in slower motions, amounts to $\frac{7}{11}$ of the same quantity; whence in a velocity of 1065 feet in 1″, (the medium of 1180 and 950) the *resisting* power of the air is augmented in no greater proportion than of 11 to 7; whereas in greater degrees of velocity, as before, it amounted very near to the ratio of 3 to 1.

That this *resisting* power of the air to swift motions, is very sensibly increased beyond what Sir Isaac's theory for slow motions makes it, seems hence to be evident. It being, as has been said, in musket, or cannon shot, with their full charge of powder, near three times the quantity assigned by that theory.

The *resistance* of a bullet of three quarters of an inch diameter, moving in air with a velocity of 1670 feet in 1″, amounting, as we said, to 10 lb. the *resistance* of a cannon ball of 24 lb. fired with its full charge of powder, and thereby moving with a velocity of 1650 feet in 1″ (which scarce differs from the other. See GUNNERY, *Append.*) may hence be determined. For the velocity of the cannon ball being near the same as the musket bullet, and its surface above 54 times greater, it follows, that the *resistance* on the cannon ball will amount to more than 540 lb. which is near 23 times its own weight. And from hence it appears how rash and erroneous the opinion of those is, who neglect the consideration of the *resistance* of the air as of no importance in the doctrine of projectiles. See PROJECTILE.

RESPIRATION (*Cycl.*)—The alternate motion of the thorax and lungs in *respiration* is evident, but it is not easy to determine the mechanism by which these motions are performed. Dr. Martin thinks this has not been accounted for in a satisfactory manner, either by Swammerdam, Borelli, Ballivi, Pitcairn, or Boerhaave, and has given us an essay on this subject in the Medic. Ess. Edinb. Vol. 1. Art. 12.

Dr. Hoadley [a] endeavours to prove, that the external intercostal muscles serve for *inspiration*, while the internal intercostals are their antagonists, depressing their ribs in *expiration*. He thinks it proved by Dr. Hales's experiments [b], that there is air in the cavity of the thorax, between the lungs and the pleura, and endeavours to take off the force of Dr. Houston's asserting that he saw the lungs and pleura contiguous. He grants, however, that sometimes there may be little or no air. He accounts for *respiration* much in the same way with those who assume the contiguity of the lungs and pleura. He joins with those who think the impetus, which the internal surface of the lungs sustains in common *respiration*, to be very little. The uses of *respiration* are, to discharge from the venal blood and chyle, such parts as are unfit to render them arterial blood, and to admit air into the blood. From this doctrine he accounts for the phænomena of the diseases of the lungs. He subjoins the picture and description of an ingenious instrument for illustrating the manner in which *respiration* is performed. —[[a] Lectures on Respiration. [b] Veget. Statics exp. 112, 113. and *Hæmastat.* p. 83.]

Organs of RESPIRATION, in fly worms. These afford us not only great matter of admiration in their general structure, but by their almost endless variety in the different species of these creatures, give ample room for the forming classes and genera from them.

The first class of these creatures is of those with variable heads, whose organs of *respiration* are principally behind, the large sensible stigmata, or breathing holes, being placed there; and which have no scaly legs, nor any regularly formed membranaceous ones; and which have, under their belly, certain fleshy protuberances, each seeming a portion of a ring, which is inflated at certain times.

These are the characters common to a vast class of these creatures, which are transformed into two winged flies; but seem never to be the marks of those which are produced from the eggs of the four winged class. *Reaumur's* Hist. Insect. Vol. 4. p. 164.

RESPONDEAS *ouster*, in law, is to answer over in an action to the merits of the cause.

RESSELA, a term used by Paracelsus to signify, as himself explains it, any thing that expels heat, in opposition to *assa*, which with him signifies any thing that promotes it.

REST (*Cycl.*)—Monsieur de Maupertuis asserts, that when bodies are in equilibrio, they must be so situated, that if any small motion be impressed on them, the quantity of action resulting will be the least possible. This he calls the law of *rest*, and from this law he deduces the fundamental proposition of statics. See Mem. de l'Acad. de Berlin, Tom. 2. p. 294.

Monsieur de Maupertuis deduces the laws of percussion from the same principle. See *Quantity of* ACTION.

REST-*harrow*, *anonis*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the papilionaceous kind. The pistil arises from the cup, and finally becomes a turgid seed vessel, in some species longer, and in others shorter, and usually containing kidney shaped seeds. The characters of the leaves are, that they usually grow three on each stalk, though sometimes they stand singly in other parts of the same plant.

The species of *anonis* enumerated by Mr. Tournefort are these. 1. The common prickly *anonis* with purple flowers. 2. The prickly *anonis* with white flowers. 3. The red flowered *anonis* without prickles. 4. The white flowered *anonis* without prickles. 5. The *anonis* with smooth procumbent stalks. 6. The least red flowered *anonis* without prickles. 7. The hairy and viscous purple flowered small *anonis*. 8. The perennial red flowered *anonis* with broad, roundish, and deeply serrated leaves. 9. The early flowering purple mountain shrubby *anonis*. 10. The Spanish shrubby *anonis* with fleshy tridentated leaves. 11. The low alpine *anonis* with a sweet fleshy root. 12. The smooth sea *anonis* with flowers standing in the alæ of the leaves. 13. The dwarf annual purple *anonis*. 14. The dwarf smooth purple flowered alpine *anonis* without prickles. 15. The Sicilian *anonis* with the appearance of the alopecuros. 16. The round leaved Spanish purple spiked *anonis* without prickles. 17. The hoary procumbent sea *anonis*. 18. The purple flowered American shrubby *anonis*, called by many *crotolaria*. 19. The great yellow viscous *anonis* without prickles. 20. The smooth *anonis* with yellow variegated flowers. 21. The broad leaved yellow annual viscous *anonis* without prickles. 22. The annual broad leaved erect Portugal viscous *anonis*. 23. The narrow leaved sea *anonis* without prickles, with yellow variegated flowers. 24. The yellow flowered dwarf *anonis* with smooth narrow leaves. 25. The little yellow French *anonis* without prickles. 26. The *anonis* with small yellow flowers. 27. The shrubby Asiatic *anonis* with large yellow flowers. 28. The shrubby Spanish *anonis* with rounder leaves. 29. The rose leaved shrubby Spanish *anonis*. 30. The broad and roundish leaved American *anonis*. 31. The creeping bituminose kidneybean-like *anonis*. *Tourn.* Inst. p. 408.

RESTY, (*Cycl.*) in the manege. A malicious unruly horse, that shrugs himself short, and will only go where he pleases, is said to be *resty*. A *resty* horse is much the same with what the French call *ramingue*. See RAMINGUE.

RESUSCITATION (*Cycl.*)—RESUSCITATION *of plants*, in chemistry, the art of reproducing a plant from its ashes. See PALINGENESIA.

Many have pretended to this art, and have shewn *resuscitated* plants in vials [c]; but all these seem only particular instances of artificial chemical vegetations, of which many others may be given. The external appearances of these resemble plants, and the ignorant may easily take them for such; but when closely considered, there is a great difference to be found.—[[c] *Boyle's* Works Abr. Vol. 1. p. 69.] See *artificial* VEGETATION.

RETCH, or RETCHES, a name given by our farmers to an iron, or a pair of irons, which in the common plow serve to fasten the sheat to the beam. The *retches* are fastened to the sheat with nails, and to the beam with pins.

RETENEGI, in the materia medica, a name used by Avisenna, and others, to express the common resin of the pine, or fir tree, and sometimes common black pitch. The lexicographers have given us storax as the explanation of *retenegi*, but this is not warranted by any passage in the authors who use the word. It is certain, indeed, that the generality of authors have confounded the several sorts of resin and pitch making trees together, and among them the pine, fir, cedar, and turpentine trees, are called by the same name, but the storax tree is never included among the number. These were only confounded together, because of the similitude of the things they produced; but the storax was too different from all these, and too precious a gem not be distinguished. See ERZ.

RETENTA, a word used by the medical writers to express things retained in the body, or which are not to be retained in a state of good health.

RETENTION *of the first stools*, in infants. See INFANT.

RETIARIUS, among the Romans, a kind of gladiator, who entered the lists armed only with a trident in his left hand, and a net in his right. He was to use his utmost address to throw the net over, and thereby entangle his antagonist; and if he missed of his aim, he was to betake himself to flight, till he had the good luck to recover his net. *Pitisc.* Lex. Antiq. in voc.

RETINACULUM, the name of a chirurgical inftrument ufed in caftration, and in the operation for a hernia, to prevent the inteftines from falling into the fcrotum.

RETORT (*Cycl.*)—The quantity of air rifing from fome fubftances is apt to burft glaffes in diftilling; Dr. Browne Langrifh has therefore given us a new contrivance of applying receivers to *retorts*, by which fuch accidents may be prevented. To his firft receiver he adapts a fecond, inferted into an opening at the top of the firft, in order to give more room to the rarefied and new generated air. To an opening, at the bottom of each of thefe receivers, he fixes a bottle, tied on clofe by means of a bladder, fo that they may be removed at any time, and another inftantly placed in their room; by which means very little of the fteam will efcape. He alfo ties on a bladder to an opening, or upper neck of the fecond recipient; and this bladder being much thinner and weaker than any of the glaffes, will always give way firft, and prevent their burfting. And even when there is the greateft danger of this accident, the fmalleft pin hole made through the top of the bladder, as foon as the fumes begin to rife, will be fufficient to let out the air as faft as it is generated. See Philof. Tranf. Nº 475. Sect. 3. where we have a figure of the whole apparatus. See alfo Tab. of Chemiftry, Nº 22, and 34.

RETREAT, (*Cycl.*) or TATTOU, in the art of war, is a beat of the drum in the evening, at the firing of a piece called the *warning piece*, at which the drum-major, with all the drums of the battalion, except fuch as are upon duty, beats round the regiment; the drums of the quarter guards, of the generals guards, and all other fmall guards, do likewife beat; the trumpets at the fame time founding at the head of their refpective troops. This is to warn the foldiers to forbear firing, and the centries to challenge, till break of day, that the reveille is beat. The *retreat* is likewife called *fetting the watch.*

RETTO *moto*, in the Italian mufic. See MOTO.

RETURNS (*Cycl.*)—RETURNS *of a mine*, in the military art, are the turnings and windings of the gallery.

RETURNUM *averiorum*, a judicial writ, the fame with *retorno habendo*. Reg. Judic. 4.

RETUSE *leaf*, *retufum folium*, among botanifts. See the article LEAF.

REVE-*land.* The land which in Domefday is faid to have been *thaneland*, and afterwards converted into *reveland*, feems to be fuch lands as being reverted to the king after the death of his Thane, who had it for life, was not fince granted out to any by the king, but refted in charge upon the account of the *reve*, or bailiff of the manor. *Spelm.* Feuds, c. 24. *Blount.*

REVERSE, in the military art, fignifies on the back, or behind. Thus we fay, a *reverfe view*, a *reverfe commanding ground*, a *reverfe battery*, &c.

REVOLUTUM *folium*, among botanifts. See LEAF.

REUTELE, in zoology, a name ufed by fome for the *umbla minor*, or red charre, a fifh common in the lakes of Germany, and of the northern parts of England and Wales. The name is originally German. *Willughby*'s Hift. Pifc. p. 196. See CHARRE.

REWARDS. Military *rewards*, among the Athenians, confifted fometimes in crowns prefented to thofe that had merited them; on which their names and noble actions were infcribed. Some had leave granted them to erect pillars or ftatues, in honour of fome god, with infcriptions fetting forth their victories. This was a favour that was feldom granted; Cimon indeed was honoured with it, but Themiftocles could never obtain the like. Another honour conferred at Athens on the valiant, was to have their arms placed in the citadel, and to be called *Cecropidæ*, or citizens of the true old blood. Others were prefented with a πανοπλια, or compleat fuit of armour. Songs of triumph were honorary compliments paid to fome. The children of thofe who were killed in battle were maintained at the public expence, till they came to maturity; at which time they were prefented before the affembly of the Athenian people with a compleat fuit of armour, one of the public minifters proclaiming before them, "that hitherto, in remembrance of "their fathers merits, the commonwealth had educated "thefe young men, but now difmiffed them fo armed, to "go forth and thank their country by imitating their fathers "examples."

Solon made a farther provifion for the parents of thofe that died in the wars, it being extremely reafonable that they fhould be maintained at the public expence, who had loft their children, the comfort and fupport of their declining age, in the fervice of the public.

As for thofe who were any wife difabled, they had an allowance from the public towards their maintenance. *Potter*, Tom. 2. p. 118, feq.

REWEY, a term among clothiers, fignifying cloth unevenly wrought, or full of *rewes*, 43 Eliz. c. 10. *Blount*, *Cowel.*

REX *mullorum*, in zoology, a name given by fome authors to a fpecies of *mullet* diftinguifhed from all the others by its having a prominent belly, and having no beards under the mouth. *Willughby*'s Hift. Pifc. p. 286. See the article MULLUS *imberbis.*

REY *grafs.* This is a hardy fort of *grafs*, much efteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing elfe will. It thrives beft of all on fower, clayey, and weeping grounds, and equally endures the fevereft droughts of fummer, and frofts of winter, fuffering no damage from either. It is the beft of all winter foods for cattle, the fhorter it is eaten the better, and it fprings the earlieft of any. There is no danger of overftocking it, for if it be left to grow too much, the ftalk becomes hard and fticky. It is beft for horfes and for fheep, and very much prevents the rotting of the latter. The beft way of fowing it is with clover. The common quantity of feed is two bufhels to an acre, but three bufhels is much better; though in fome lands, where the clover is likely to fucceed very well, they fow eight pounds of clover feed, and one bufhel of *rey* feed to an acre, and this makes a crop that will laft feven or eight years.

Some mow it as hay, and thrafh it for the feed, which about London fells from half a crown a bufhel to three fhillings. Four or five quarters of this feed will be fometimes produced from an acre of the *grafs*. If at any time a field of this *grafs* is found to grow thin, it is only neceffary to ftrew on a bufhel of the feed, and roll it with a wooden roller, and the plants rifing from this addition will make the whole crop fufficiently thick. *Rey grafs* has this great advantage, that it kills weeds without any other fown plant; even thiftles cannot grow among it. When the *rey grafs* is cut for hay before perfectly ripe, the hay is the better, but the feed will not grow fo well. When the feed is newly thrafhed, it muft not be laid too thick, for it is very apt to heat and ferment, and the whole will be fpoiled. *Mortimer*'s Hufbandry, p. 40.

RHABARBARUM, in botany, the name given to the plant of which *rhubarb* is the root, and which Mr. Tournefort makes to conftitute of itfelf a peculiar genus, of which there is no other fpecies. The characters he delivers of the genus are thefe. The flower confifts of one leaf, formed into the fhape of a bell, and divided into feveral fegments; from the bottom of this rifes a piftil, which ripens into a thick fruit, containing one large triangular feed, which is fo affixed to its triangular capfule as it ripens, that there is no feparating it from it. *Tourn.* Inft. p. 89.

RHABDOMANTIA, Ραβδομαντεια, among the antients, a fpecies of divination performed with rods. *Potter*, Archæol. Græc. l. 2. c. 16. Tom. I. p. 334.

RHABDONALEPSIS, Ραβδον Αναληψις, among the Greeks, the reception or elevation of the rod, a feftival kept every year in the ifland of Cos, at which the priefts carried a cyprefs tree. *Potter*, Archæol. Græc. l. 2. c. 20. Tom. I. p. 429.

RHABDOPHORI, Ραβδοφοροι, among the Greeks, officers appointed to preferve peace and good order, and to correct the unruly at their public games. *Potter*, Archæol. Græc. Tom. I. p. 448.

RHABDUS, Ραβδος, among the antients, the iron rod with which the boy rolled the *trochus*. See TROCHUS.

RHAGADIOLUS, in botany, the name of a genus of plants, the characters of which are thefe. The flower is compofed of a number of femiflofcules ftanding on the embryo fruit, and each perforated in its bottom part by the capillament which arifes from that embryo. Thefe are all contained in one common cup, the feveral leaves of which afterwards become fo many pods, difpofed in the form of a ftar, and containing long fhaped and pointed feeds.

There is only one known fpecies of this plant, which is the ftarry headed *hawkweed* of authors, or the *hawkweed* with falcated feeds. *Tourn.* Inft. p. 479.

RHAGE, a word ufed by medical writers for a fiffure or chap in any part. The ftones of grapes are alfo by fome called *rhages*; and by others the fame word is made to exprefs the extremities of the fingers or toes.

RHAMNOIDES, a name given by Tournefort, and others, to a genus of plants, called by Linnæus *hippophae.* See the article HIPPOPHAE.

RHAMNUS, *buckthorn*, in botany, the name of a genus of plants, the characters of which are thefe. The flower is compofed of only one leaf, and is of the fhape of a funnel, and divided into four fegments at the edge. From the bottom of this there arife a number of ftamina furrounding a piftil, which finally becomes a foft and juicy berry, ufually containing four callous feeds, gibbofe on one fide, and flat on the other.

The fpecies of *rhamnus*, enumerated by Mr. Tournefort, are thefe. 1. The common *buckthorn*. 2. The leffer *buckthorn*. 3. The fmaller *buckthorn* with oblong and narrow leaves. 4. The green flowered *buckthorn* with black berries. 5. The fmall Spanifh *buckthorn* with leaves like box. Thefe are called by fome authors *lyciums*. 6. The Spanifh *buckthorn* with larger box-like leaves. 7. The olive leaved Spanifh *buckthorn*. 8. The Spanifh *buckthorn* with hypericum leaves. 9. The Spanifh *buckthorn* with the leaves and whole appearance of the *ceratia*, or *filiqua*. 10. The capillaceous leaved Spanifh rock *buckthorn*. *Tourn.* Inft. p. 593.

RHAPSODOMANTIA, Ῥαψωδομαντεία, among the antients, a ſpecies of divination performed with the works or rhapſodies of the poets, particularly Homer and Virgil, who were looked upon as divine and inſpired perſons; whence this kind of divination was called *ſortes Homericæ* and *Virgilianæ*. *Potter*, Archæol. Græc. l. 2. c. 16. Tom. I. p. 333. See SORTES, *Cycl.*

RHEEDIA, in botany, the name of a genus of plants, ſo called from Mr. Van Rheed. The characters of the genus are theſe: the flower has no cup. It conſiſts of four petals, which are of an oval figure, and are hollowed, and expanded wide open. The ſtamina are five filaments. The germen of the piſtil is globoſe. The fruit is ſmall, and of an oval figure. It is ſucculent, and conſiſts only of one cell, and contains three very large ſeeds, which are of an oval oblong figure, and marked with ſtrangely irregular lines, reſembling ſeveral characters. *Linnæi* Gener. Plant. p. 523. *Plumier*. 18.

RHEGMA, a word uſed by the antients to expreſs any breaking, or burſting of a ſoft part without a wound, but moſt frequently for abſceſſes breaking inwardly.

RHENONES, among the antient Germans, a kind of garment covering the ſhoulders and breaſt down to the middle. It was either entirely made of ſkins, or covered over with them; the long hair of which being outward, proved a good defence againſt rain. *Pitiſc.* in voc.

RHEO-STATICS, is uſed by ſome for the ſtatics, or the ſcience of the equilibrium of fluids. *Caſtel*. Math. Univ. p. 73.

RHEUMATISM (*Cycl.*)—In obſtinate *rheumatiſms* ſmall doſes of emetic wine are much recommended by Dr. Huxham.

RHEXIA, in natural hiſtory, the name of a genus of plants, the characters of which are theſe. The perianthium conſiſts of one leaf; it is of an oblong figure, tubular, inflated at the bottom, and divided into four ſegments at the mouth. It remains after the flower is fallen. The flower conſiſts of four petals; they are of a roundiſh figure; they ſtand expanded, and are affixed to the cup. The ſtamina are eight capillary filaments longer than the cup. Theſe are affixed to the cup, and are terminated by long drooping antheræ. The germen of the piſtil is roundiſh, the ſtyle is ſimple, and of the length of the ſtamina. The ſtigma is ſomewhat thick and obtuſe. The capſule is contained within the belly, or inflated part of the cup; it is roundiſh, compoſed of four valves, and containing four cells. This contains a number of roundiſh ſeeds. It is to be obſerved, that in ſome ſpecies of this genus the calyx is ſmooth, in others it has ſeveral hairs diſpoſed in a ſtellated manner. *Linnæi* Gen. Pl. p. 161. *Pluknet*, f. 173. f. 4. *Gronovius*.

RHINANTHUS, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium is roundiſh, but compreſſed, ſomewhat inflated and compoſed of one leaf, divided into four ſegments at the end. This is permanent, and does not fall with the flower. The flower is of the labiated kind, and conſiſts of one petal. Its tube is of the length of the cup, its limb open but compreſſed at the baſe. The upper lip is hooded, compreſſed, marginated and narrow; the under lip is broad, flat, and obtuſe, and lightly divided into three ſegments; the middle one ſomewhat larger than the reſt. The ſtamina are four filaments, of the length of the upper lip of the flower, under which they are hid, two of them are ſomewhat ſhorter than the others. The antheræ are incumbent, and are bifid and hairy. The germen of the piſtil is oval and compreſſed. The ſtyle is capillary, and of the length of the ſtamina, or ſomewhat more than that. The ſtigma is obtuſe and bent. The fruit is an erect orbicular but compreſſed capſule, it is compoſed of two valves, and divided into two cells. The ſeeds are numerous, and of a flatted figure, and fall out by the opening of the capſule at its ſides. *Linnæi* Gen. Pl. p. 282.

RHINE (*Cycl.*)—RHINE, in ichthyology, a name given by Ariſtotle, Appian, and moſt of the Greek writers to that ſpecies of the *ſqualus*, which we uſually call the *ſquatina*; the *ſquatus* of Iſidore and Pliny. Artedi has diſtinguiſhed this from all the other ſpecies of the *ſqualus*, by the having no pinna ani, and the mouth in the extremity of the ſnout.

RHINECHITIS, a name of a chirurgical inſtrument, uſed for ſyringing the noſtrils.

RHINGAU, a name given by ſome authors to the *lavaretus*, a ſmall fiſh, caught in the German lakes, and ſent in pickle into many parts of the world. *Willughby*'s Hiſt. Piſc. p. 183. See the article LAVARETUS.

RHINOBATUS, in zoology, the name of a flat cartilaginous fiſh, of the *ſquatina*, or *monk fiſh* kind, but differing from it in this, that the body is proportionably longer, and the head is more pointed; and the mouth is a great way below the end of the ſnout, and placed under the head. It is from three to four feet long, and is common in the Mediterranean, and brought to market in ſome parts of Naples. *Fab. Column.* p. 119.

RHINOCEROS, in zoology, the name of a genus of quadrupeds, ſo called from an horn growing on their noſe.

Of this genus there are only two known ſpecies. 1. The *rhinoceros* with only one horn on its noſe; and, 2. The *rhinoceros* with two horns.

In the year 1739 we had a young *rhinoceros* ſhewn in England, of which Dr. Parſons has given a very accurate account in the Philoſophical Tranſactions.

The creature fed on rice, ſugar, and hay; his keeper uſed to mix the rice and ſugar in the following manner: ſeven pounds of rice and three pounds of ſugar made the proviſion for one day; he eat this at three meals; and beſides this he eat about a truſs of hay every week, and a large quantity of greens that were brought to him, at different times, and of which he ſeemed more fond than of dried food. He drank often, and always ſwallowed a large quantity of water at a time. See Tab. of Quadrupeds, N° 13 and 14.

He appeared very peaceable in his temper, and bore to be handled on any part of his body, with great patience, except when he was hungry; but he was then always outrageous, as alſo when he was ſtruck. His moſt violent paſſions, even on the laſt occaſion, were however always immediately appeaſed by giving him victuals.

Notwithſtanding the lumpiſh aſpect, and heavy make of this creature, he would jump about very nimbly in his fits of paſſion, and often leap to a great height; and one common mark of his fury was the ſtriking his head againſt the walls, or any thing elſe that was in the way, and this he would do with terrible violence. He was very apt to fall into theſe paſſions in a morning before his rice and ſugar were given him, and from the whole he appeared quite untractable, and ſeemed able, in his paſſions, to have run ſo faſt, as that a man on foot could not have eſcaped him.

This creature was two years old, and did not exceed a young heifer in height, but was remarkably broad and thick. His head was very large; and the hinder part of it, near the ears, remarkably elevated above the reſt of the face, which was flat, and ſunk down, in a remarkable manner in the middle, riſing again toward the origin of the horn, but in a much ſmaller degree. The horn ſtands upon the noſe of the animal as upon a ſort of hill; and when the ſceleton of the head is ſeen, that part of the ſkull on which the horn is fixed, is found to riſe into a blunt cone, to anſwer to a cavity in the baſis of the horn, which is very hard and ſolid; in other reſpects, having no manner of hollow, or core, like thoſe of other quadrupeds. The horn in this young animal did not riſe above an inch high from its tough baſis, and was black and ſmooth at the top, but ragged downwards; and the determination of its growth is backward, not ſtrait up; this is very evidently ſeen in the horns of old *rhinoceroſes*, which are always curved in a conſiderable degree that way. If we conſider the proportion of this animal's ſize, to the length of its horn, and thence carry the proportion to that between the large horns we ſee in the muſeums of the curious, we muſt ſuppoſe the animal of a very ſtupendous ſize, when at its full growth. Phil. Tranſ. N° 470. p. 530.

The ſides of the under jaw, in this creature, ſtand very wide aſunder, ſlanting outward to the lower edge, and backward to the neck; the edges turn outwards from this ſtructure of the bones, and the head neceſſarily looks very large. That part of the head which reaches from the forepart of the horn to the upper lip may be called the noſe; this is very thick, and bulky, and has a kind of circular ſweep down towards the noſtrils; on all this part there are a great number of rugæ or wrinkles.

The noſtrils are ſituated very low, in the ſame direction with the opening of the mouth, and not more than an inch from it; and when viewed in a foreview, the whole noſe, from the top of the horn to the verge of the lower lip, is ſhaped like a bell. The under lip is like that of an ox, but the upper more like that of a horſe, and he uſes it as that creature does, to gather up hay from the rack, or graſs from the ground; but, with this ſuperior advantage, that this creature has a power of extending this lip to ſix or ſeven inches in length from the noſe, and there drawing it to a point; with this lip, thus extended, the creature is able to graſp a ſtick, or any ſmall ſubſtance, and hold it extremely faſt; and this power of prolonging the lips ſerves, in many purpoſes, to the ſame end as the trunk of that other unweildy animal the elephant.

The tongue of the *rhinoceros* is ſaid to be ſo rough as to be able to rub a man's fleſh off from the bones; but, in this young ſubject it was ſo ſoft, that it reſembled that of a calf. It may poſſibly grow harder with age; but the ſtory of its effects ſeems of a piece with the many other falſe marvels reported of this animal. The eyes are dull and ſleepy, much like thoſe of a hog in ſhape; he ſeldom opens them entirely; and it is to be obſerved, that they are ſituated nearer the noſe than thoſe of any other known quadruped. The ears are broad and thin toward the top, much like thoſe of a hog; but they ariſe each from a narrow round baſe, with ſome wrinkles on it, which iſſues out of a ſinus, as it were ſurrounded with a fleſhy fold. The neck is very ſhort, and has two folds, or wrinkles, wholly ſurrounding it, only that the anterior one is broken underneath; and has a flap hanging

hanging from it so deep, that it would contain a man's hand; from the middle of the posterior plica of the neck, there arises another, which passing backward, is lost before it reaches the body. The shoulders are thick and heavy, and have each a fold passing downward. The body is very large and thick, and stands out at the sides like that of a cow with calf. The legs are very thick and strong, they are round, and somewhat smaller downwards than in the upper part; and when the creature stands upright they bend inward at the knee, so that they are nothing like strait. In some quadrupeds the fetlock bends to the weight of the animal, but in this creature there is no appearance of any such bending, so that he seems to stand upon four stumps, especially when viewed behind. He has three hoofs upon each foot forward, but the back part is a great mass of flesh, rough like the rest of the skin; and the sole of the foot is very plump and callous in the surface, but easily yielding to the pressure from the softness of the subjacent flesh. Its shape is like that of a heart, with a blunt apex before, and a broad base behind. The tail is very small in proportion to the size of the animal, not exceeding seventeen or eighteen inches in length, and but thin or slender; it is very rough, and has a kind of twist or stricture towards the extremities, ending in a flat mass; this gave occasion to some authors to compare the whole tail to a spatula; on the sides of this flat part there grew a few short, but very thick and strong black hairs, but these grow much longer in the more advanced state of the creature; and are not round, like other hairs, but flat, like small pieces of whalebone. The creature has no other hair about it, except a very small quantity at the edge of the ears. See Tab. of Quadrupeds, N° 13 and 14.

The penis of the male *rhinoceros* is of a very remarkable structure, being inclosed in two cases. The female differs in nothing from the male except in the pudenda, which are shaped like those of a cow.

The skin of the *rhinoceros* is thick, and seems almost impenetrable; it feels like a piece of board of half an inch thick. It is covered in all parts, more or less, with a sort of incrustations, resembling scales. These are small on the neck, and largest of all in the shoulders and hips; between the folds of this thick skin, the cuticle, which is left bare, is soft, and easily penetrable. The scabby incrustations of the skin have been called scales, by some writers; but this is a very wrong term, for they have nothing of the nature of scales, nor any thing of regularity in them.

The creature is of the retromingent, and therefore probably of the retrogenerative kind; the penis, when erect, is not more than nine, or at the utmost ten inches long, and is curved backward at the end. This was the description of the *rhinoceros* shewn in England at this time, and of all the others that have been seen in this part of the world as to the general characters; but though these creatures, which we have seen, have but one horn, it is very certain, that there is a species of *rhinoceros* which has two. Martial has mentioned a *rhinoceros*, as shewn in the amphitheatre at Rome, which had two horns; but his commentators supposing the copies erroneous, have been at great pains to alter it, so as to make it express what they had seen or heard of, that is a *rhinoceros* only with one horn: but it appears, from almost indisputable testimony, that there not only is in nature such a *rhinoceros* with two horns, but that such were shewn in the public sports at Rome, and therefore the text seems to have been very right, and the commentators in the wrong. The creatures we have seen have indeed only had one horn; and the accounts of travellers, and the great number of horns preserved in the cabinets of the curious, which are all single, seem to prove this; but though the *rhinoceroses* of Asia are all one horned, yet it is certain, that there is a kind found in Africa which has two horns, and not less certain, that the Romans had beasts from this last part of the world as well as the other. Peter Kolbe, in his voyage to the Cape of Good Hope, describes *rhinoceroses*, which he saw, and which had a horn on the nose, and another close behind it. Sir Hans Sloan's museum affords two horns of a *rhinoceros*, standing just as this author has described them, which are still fixed to the same integument; and we are convinced of the Romans being acquainted with this species, from a brass medal of Domitian, which has on it a *rhinoceros*, with two horns on the nose placed in this manner.

Redi, who has been very sagacious in discovering the falsity of many of the pretended medicines taken from animals, yet gives us, on the testimony of his own experience, an account of some very remarkable virtues in the parts of the *rhinoceros*. The blood he assures us is excellent in colics and in dysenteries. The decoction of the skin, he assures us, is a grand stomachic antidote, and the horns are very valuable and alexipharmic. *Redi*'s Esperience.

RHINOCEROS *avis*, the *rhinoceros bird*, a name given by authors to a species of Indian raven, called by others *corvus indicus cornutus*. The beak of which is frequently brought over into Europe.

It is a very ugly bird, and of a very rank smell. It much exceeds the European raven in bigness, and its head and neck are very thick. Its eyes are very large, and its beak of a very remarkable figure, having a large and thick horn like protuberance on its upper part. The whole beak is bent like a bow, not hooked at the end like the beaks of the hawk, &c. It is of a yellowish white below, and on the upper part toward the head is of a fine gay red, and the rest of a yellowish white: the upper chap is serrated. The horn grows out from the head with this and runs along it, and bends up at its extremity; its upper and under part are red, its middle yellow. The bird feeds on carrion, and the guts of dead animals. *Aldrovand* de Avibus.

RHINOPTES, a word used by the antients to express a person, who from an ulcer in the great canthus of the eye, laying open the passages to the nose, can see through his nostril.

RHIPTASMOS, a word used by the antients, to express a restlessness and frequent tossing about, a very common symptom in fevers.

RHIZAGRA, the name of a chirurgical instrument used to extract the stumps of teeth.

RHIZOPHORA, in botany, the name given by Linnæus to a genus of plants, described under the name of *mangles* by Plumier, the characters of which are these: the perianthium is erect, and is composed of one leaf, divided into four oblong segments. The flower is erect, and is composed of one petal, divided into four segments, and is shorter than the cup. The stamina are twelve erect filaments, alternately shorter one than the other, and the antheræ are small. The germen of the pistil is subulated; there is scarce any style; the stigma is acute, and the receptacle is of an oval figure; this becomes fleshy, and contains the base of the seed. The seed is single, and extremely long; it is of a clavated figure, and pointed at the end. There is some variation in the number of the stamina in this plant; they are always, however, of some number between eight and twelve, these being the highest and lowest extremes. *Linnæi* Gen. Pl. p. 207. *Plumier* Gen. 15. Hort. Mal. Vol. 6. p. 31, 32.

RHODIOLA, in botany, the name given by Linnæus to a genus of plants, commonly called *rhodia*. The characters of which are these: it produces two kinds of flowers, the one hermaphrodite, acting as male flowers; the other simply female. In the male flower, the cup is a concave erect perianthium, divided into four obtuse segments, and not falling with the petals. The flower consists of four petals, which are oblong, obtuse, erecto-patent, and twice as long as the segments of the cup: these fall soon after they are open: they have four erect nectaria, surrounded with a thin rim, and somewhat shorter than the cup. The stamina are eight pointed filaments, longer than the petals of the flower. The antheræ are simple. The pistil has four oblong and pointed germina. The styles and stigmata are very imperfect. The fruit that should succeed these is very abortive.

In the female flower the cup is of the same kind with that of the male. The flower is composed of four rude, erect, and obtuse petals, of the same size with the segments of the cup, and remaining with it. The nectaria in this flower are the same with those of the male. The pistil has four oblong pointed germens, which go off into so many strait simple styles, crowned with obtuse stigmata. The fruit consists of four corniculated capsules, which are univalve, compressed inwards, and opening in that part. In these capsules are contained a number of seeds of a roundish shape. *Linnæi* Gen. Pl. p. 498.

RHODITES *lapis*, the *rose stone*, in natural history, the name given by authors to a kind of *astroites*, or *star-stone*, in which the figures more represent roses than stars: they are in both owing to coralloide bodies immersed in the stone; which, according to their various species, afford a different figure, when cut transversely, in the cutting the stone into plates for use. See Astroites and Star-*stone*.

RHODIUM *marmor*, a name given by the antients to a marble brought from Rhodes; it was of a good white, but inferior to the Parian, and was used by the Romans in their public buildings, and sometimes in statuary.

RHODOMELON, a name given by the antients to a confection made of roses, quinces, and honey, used as a grateful astringent and detergent in many cases.

RHODOPUS *gallinula*, in zoology, a name given by some authors to the bird more usually known by the name *tringa*. *Gesner* de Avid. See the article Tringa.

RHOITES, the name of a medicine among the antients, which is a sort of rob of the juice of pomegranates. Dioscorides describes it as the simple juice of the fruit, evaporated over the fire to the consistence of an extract; but Paulus Ægineta gives the receipt to be three parts juice of pomegranate, and one part honey, boiled to the evaporation of a third part. So that the *rhoites* of Dioscorides was a true rob of pomegranates; the other, rather honey of pomegranates, like our honey of roses.

RHOMB. See the article Rhombus, *Cycl.* and *Suppl.*

RHOMBO, the name of a peculiar fish of the *rhombus*, or turbot kind, called *rhombus aculeatus* by Aldrovand, Gesner, and other authors. It is a large fish, of an ash coloured green on the back, and white on the belly. It has no scales;

but the ſkin of its back is divided by lines, ſomething in the manner of the ſkins of ſnakes. The mouth is very large, and is well furniſhed with teeth; and the palate has a number of tubercles, armed alſo with a ſort of teeth. It feeds on fiſh, and its fleſh is very delicate. It is very common in the markets at Venice, and is caught in the neighbouring ſeas, and in many other places. *Willughby*'s Hiſt. Piſc. p. 92. *Geſner*, p. 778. *Aldrov.* de Piſc. l. 2. c. 48.

RHOMBOIDÆUS *major* and *minor*, names given by Albinus to what he makes two muſcles; though Winſlow and others account it only one. What Winſlow calls the inferior portion of the rhomboidalis, Albinus calls *rhomboidæus major*, and what he calls the upper portion of that muſcle, Albinus calls *rhomboidæus minor*. See the article SCAPULA.

RHOMBOIDALIS. See the articles RHOMBOIDÆUS and SCAPULA.

RHOMBOIDES, in anatomy, a muſcle, which is a thin, broad, and oblique ſquare fleſhy plane, ſituated between the baſis of the ſcapula and the ſpina dorſi. It may be divided into two portions, one ſuperior, the other inferior, which ſometimes appear ſeparate. The ſuperior portion, which ſeems in ſome ſubjects to be made up of two, is fixed by an inſertion wholly fleſhy in the two or three loweſt ſpinal apophyſes of the neck, and partly in the poſterior cervical ligament. The inferior portion is fixed by a tendinous plane in the three or four uppermoſt ſpinal apophyſes of the back.

Theſe two portions, of which the inferior is much the broadeſt, being united, are inſerted in the edge of the baſis ſcapulæ, from the ſmall triangular ſpace to the inferior angle, the ſuperior portion covering a ſmall portion of the angularis at its inſertion. This whole muſcle is covered by the trapezius, and covers the ſerratus poſticus ſuperior, being joined to each of theſe muſcles by a filamentary or cellular ſubſtance. *Winſlow*'s Anatomy, p. 174.

RHOMBOIDIA, in natural hiſtory, the name of a genus of ſpars, given them from their being of a rhomboidal form. They owe this figure to an admixture of particles of iron, and conſiſts of ſix planes.

Of this genus there are only two known ſpecies. 1. A white thin one with very thin cruſts; and 2. A whitiſh brown thick one with thicker cruſts. Theſe are both found in the foreſt of Dean in Glouceſterſhire, and in other places where there are iron ores.

RHOMBUS (*Cycl.*)—*Solid* RHOMBUS, in geometry, two equal and right cones joined together at their baſes.

RHOMBUS, in zoology, a genus of fiſhes, which are oviparous, and have a flat, ſhort, and ſomewhat ſquared body, and ſwim on one ſide. The turbot and other fiſh of that make, are of this genus. The ſides of theſe fiſh are equal, but their angles unequal. *Willughby*'s Hiſt. Piſc. p. 93.

RHOMBUS, in conchyliology, the name given by the generality of authors to a genus of the ſhell fiſh, much more properly called by ſome *cylindrus*. See CYLINDRUS.

RHOPALOSIS, a diſtemper of the hair deſcribed by the antients, and ſeeming to be the ſame with what we call the *plica polonica*, being a ſort of matting together of the hair into long and thick treſſes.

RHOPE, a word uſed by the Greek writers, to expreſs a violent tendency of the humors to any particular part of the body.

RHOX, a word uſed by ſome authors to expreſs the tunica uvea of the eye.

RHUBARB (*Cycl.*)—The Indian *rhubarb* ſown in our gardens has this peculiar property, that it yields a fine and clear gum. This is perfectly white and pellucid, and in the months of June and July is ſo plentiful, that an ounce may ſometimes be gathered at a time from one plant of it. It exſudates of itſelf from all parts of the ſtalks and ribs of the leaves, and ſometimes from the under part of the leaves themſelves. It ſtands in ſome places in large drops, and in others the ſtalks, &c. ſeem only to be covered with a thin layer of it; and the under part of the leaves in ſome have it in form of twiſted wires or long icicles. The plant may always be ſeen wounded by a ſort of cauſtic in the places where the germen makes its way out, and theſe may be followed with any pointed inſtrument through the ſkin; in ſome parts of the plant this juice is found to be turned gummy within it, and looks like clear ice. As this is the only known herbaceous plant, that yields a true gum like that of trees, it would be worthy obſervation, whether or not ſome of our own plants have ſome tendency of nature, to form a juice of the ſame kind. It would be moſt proper to look for this in the plants of the ſame genus, and as nearly related to the *rhubarb* as we can. The docks ſo common about our fields are of the ſame genus; and the ſorrel ſhews, by its taſte, that it is particularly allied to the plant; for both are alike of the dock kind, and both alike ſour. It would be proper to look carefully about the leaves of ſorrel a little before it flowers, to ſee whether any thing like the ſame gum appears on it.

There is yet this farther analogy between this *rhubarb* and our common ſorrel; that the huſks of our ſorrel, boiled in water, with a little alum, turn it to a fine red colour; and the huſks of *rhubarb* do the ſame, and both the one and the other often turn red in decaying.

The juice of the roots of this *rhubarb*, extracted by bruiſing and ſteeping it in common water, when the liquor is ſtrained and evaporated, becomes only a clear uninflammable gum, and melts in the flame of a candle. This gum, as well as that of the ſtalks and leaves, is of an inſipid taſte; and it is obſervable, that though the plant naturally yields it in ſo large a quantity, yet it will not flow from wounds made by art in any part of the plant. Upon the conſideration of the inſipid taſte of this gum, and its ſolubility in water, we may find ſome probable conjecture, in regard to the different virtues of this plant in purging and binding. The woody fibres have a ſtrong taſte; and, in all probability, are alone endued with the aſtringent quality. An infuſion of *rhubarb* is known to purge, and a powder of it to bind: the reaſon is eaſily ſeen on this conſideration. The water in the infuſion takes up all this gummy juice, and its other juices, but leaves the fibroſe part behind, in conſequence of which it ought to purge without binding; but in caſe of giving the powder, the juices are in great part evaporated in the drying, and the woody part left almoſt alone; it therefore purges but little, and proves powerfully aſtringent. Phil. Tranſ. N° 224.

RHUS, *ſumach*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the roſaceous kind, and is compoſed of ſeveral petals, diſpoſed in a circular form. The piſtil ariſes from the cup, and finally becomes a roundiſh fruit, with a depreſſion on one ſide, which gives it ſomewhat of a kidney like ſhape, and containing a ſeed of the ſame figure.

The ſpecies of *ſumach* enumerated by Mr. Tournefort are theſe. 1. The common or elm leaved *ſumach*. 2. The Virginian *ſumach*, and 3. The Canada *ſumach* with long leaves ſmooth on both ſides. *Tourn.* Inſt. p. 611.

RHUSELINUM, in botany, a name given by ſome authors to the *ranunculus*. *Ger.* Emac. Ind. 2.

RHYNE, in botany, a name uſed by ſome authors for the camphor tree. *Breyn.* Prod. VI. p. 4.

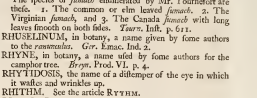
RHYTIDOSIS, the name of a diſtemper of the eye in which it waſtes and wrinkles up.

RHITHM. See the article RYTHM.

RIB. See RIBS, infra.

RIBATTUTA, in the Italian muſic, a ſtriking or ſounding the ſame note over again. Hence,

RIBATTUTA *di gola*, one of the graces in ſinging, is performed by repeated beating or ſtriking a note, from that which is immediately above it. See example A. It differs from a ſhake.



RIBATTUTA *di gola doppia*. See example B. This is pretty near what the French call *tour de goſier*, or *double cadence*. *Broſſard.* Dict. Muſ.

RIBESIA *nigra*, *black currants*, have been long famous in England for quinſies and ſore throats, ſo as to obtain the name of ſquinancy or quinſy berries. See GROSSULARIA.

RIBS (*Cycl.*)—The number of theſe varies in different ſubjects, ſometimes in one ſide only, and ſometimes in both.

Anatomiſts have divided each *rib* into the middle part or body, two extremities, the one anterior, the other poſterior; two ſides one external and convex, the other internal and concave; two edges, one ſuperior and the other inferior; and two labia in each edge, one external, the other internal. The poſterior extremity, which may be called the head of the *rib*, is articulated with the vertebræ of the back. At the anterior extremity freſh *ribs* are lengthened out by cartilaginous epiphyſes, ſtuck into their bony ends. Each of the true *ribs*, at the poſterior extremity, has two ſmall cartilaginous impreſſions, diſtinguiſhed by a kind of angle, by which they are articulated with the lateral cartilaginous impreſſions in the bodies of two vertebræ of the back; but the firſt *rib* has no more than one ſuch impreſſion, being articulated with one vertebra only. At a ſmall diſtance from the head of this extremity poſteriorly is another cartilaginous impreſſion on each ſide, a little convex, and cloſely joined to a ſmall tuberoſity. By theſe the *ribs* are articulated with the lateral cartilaginous impreſſions in the tranſverſe apophyſes of the dorſal vertebræ; and the tuberoſities ſerve for the inſertion of the ligaments; the portion which lies between the head and theſe impreſſions is contracted, and repreſents a neck. When the poſterior extremity of a *rib* is articulated with two vertebræ, the ſecond articulation is always with the tranſverſe proceſs of the loweſt two. Between the tuberoſity and middle part of the *ribs*, there is on their outſide a kind of oblique rough angle of different breadths. In the firſt *rib*, this angle is not diſtinct from the tube-

tuberoſity; in the ſecond, it reaches but to a ſmall diſtance from it; in the third *rib*, this diſtance is ſtill greater, and from thence it continues to increaſe gradually all the way to the third falſe *rib*; ſo that if we look directly at the back of a ſceleton, theſe angles repreſent the legs of a pair of compaſſes opened pretty wide. On the inſide of the *ribs*, toward the lower edge, we obſerve a groove reaching all the way from the angle to the extremity, and that chiefly in the five lower true *ribs*, and the three firſt falſe ones. The upper edge of the three firſt *ribs* is ſharp, the lower a little rounded. The upper edge of the third is more obtuſe, and the lower a little more flat. In the reſt, the upper edge is rounded, the lower, more or leſs ſharp.

In all the *ribs* the anterior extremity is lower than the poſterior; the *ribs* are much more crooked in the back than in the forepart; the appendices, epiphyſes, or cartilaginous portions of the true *ribs*, increaſe in length, as they deſcend in the ſame manner as the *ribs* themſelves; the cartilages of the firſt three or four *ribs* lie nearly in the ſame direction with the *ribs* themſelves. In the *ribs* below theſe, the cartilages make angles, at which they turn upward towards the ſternum, and this curvature increaſes in proportion as the *ribs* deſcend; and the loweſt cartilages, in changing their direction upwards, lie very cloſe to each other, and thoſe of the laſt two *ribs* have often, at their inferior edge, a ſort of apophyſis or production, by which they are connected with the cartilages immediately below them. The laſt two *ribs* extend conſiderably in breadth toward their lower ſharp edges, from the angle for a good diſtance anteriorly. Afterwards they contract in breadth and increaſe in thickneſs, forming a ſort of neck, a little longer than that at their poſterior extremity; then their breadth begins to increaſe again, by degrees, to the anterior extremity. In all the *ribs*, this extremity terminates in a cavity, in which the cartilages are grafted. The three uppermoſt falſe *ribs* increaſe in breadth from the angle forward, and the grooves are moſt conſiderable in theſe. They have alſo heads, necks, tuberoſities, and angles, almoſt the ſame as in the laſt true *ribs*. All the falſe *ribs* have cartilaginous appendages; the firſt of which is longeſt, and fixed to the cartilage of the laſt true *rib*; the two following are united together at their extremities, and the two laſt are connected only to muſcles and ligaments. They are both very ſhort, eſpecially the laſt, which is not above a quarter of an inch in length, and all theſe cartilages of the falſe *ribs* are pointed at their extremities.

The *ribs* are articulated anteriorly with the ſternum, and behind with the vertebræ of the back; the firſt *rib* is entirely united with the ſternum, by means of its cartilage, and in the ſix following the extremities of the cartilages join that bone. The three upper falſe *ribs* are joined to each other by the extremities of their cartilages; the connection of the *ribs*, with the vertebræ of the back, is for the moſt part by ginglymus. The ten upper *ribs* are confined to two motions only, upward and downward; whereas the two laſt are left more at liberty, and are therefore termed floating *ribs*. *Winſlow*'s Anatomy, p. 65.

Cartilages of the Ribs. All the *ribs* have cartilaginous portions, which differ from each other in length, breadth, incurvations, adheſions, and in their extremities. It is to be obſerved, that theſe cartilages are white, more poliſhed, broader and thicker in their natural ſtate, than in the dried ſceleton. The cartilages of the falſe *ribs* are naturally ſofter, and more pliable than thoſe of the true; the middle or inner ſubſtance of theſe acquires the conſiſtence of bones in old age, and their extremities ſome times oſſify, and are inmoveably fixed to the ſternum. Ibid. p. 149.

Ligaments of the Ribs. All the *ribs* are connected to the bodies of the vertebræ by ſtrong, ſhort, ligamentary faſciculi, fixed by one end round the foſſula in the vertebræ, and by the other round the head of each *rib*. They are alſo tied together by thin ligaments, which go from the cartilage of each *rib* obliquely to that of the next. The ten uppermoſt *ribs* on each ſide are connected to the tranſverſe apophyſes of the vertebræ of the back by ſtrong, ſhort, articular ligaments fixed to the tuberoſities of the *ribs*, and round the foſſula of the apophyſes; and this much in the ſame manner with thoſe which go between the heads of the *ribs* and bodies of the vertebræ: both theſe articulations are provided with capſular ligaments. The eleventh *rib* on each ſide having no articulation with the tranſverſe apophyſes, is connected to them by auxiliary ſtrong ſhort ligaments fixed in its neck. The laſt *rib* is only joined by its head to the body of the twelfth vertebra of the back; but it is connected, in a particular manner, to the tranſverſe apophyſis of the firſt vertebra of the loins by a broad ligament, fixed in the whole upper edge of the apophyſis, and in the lower edge of the *rib*, though about two thirds of its length. The firſt true *rib* has no ligamentary connection with the ſternum, the cartilaginous ſymphyſis being ſufficient; the reſt are cloſely joined to that bone by ſmall ligamentary portions, fixed by one end round the extremity of the cartilage, and by the other round the notches in the ſternum. The cartilage of the firſt falſe *rib* is joined to that of the laſt true *rib*, by ſeveral ſhort filaments, which go from the lower edge of the one to the upper edge of the other near its ſmall extremity. The other falſe *ribs* are connected together much in the ſame manner; except that the filaments, by which the fourth is connected to the third, are longer than thoſe above them, and thoſe between the fifth and fourth are much longer than any of the reſt; and for this reaſon theſe *ribs* are leſs ſteady than the others. The ligamentary expanſions of the vertebræ are in place of a perioſteum, but the *ribs* and ſternum have a perioſteum like other bones, only that the cartilaginous portions of the *ribs* generally give their covering the name of a pericardium.

Diſlocated Ribs. The *ribs* are ſometimes, though but ſeldom, diſlocated; for they are ſometimes diſplaced by ſome external violence, and thruſt either upwards or downwards, outwards or inwards. They cannot eaſily indeed be luxated outwards, becauſe prevented by the vertebral proceſſes, and reſiſted by very thick and ſtrong muſcles; but when they are driven into the cavity of the thorax, which oftener happens, they not only lacerate the pleura, or membrane, which lines the cavity of the thorax, but generally do great injury alſo to the contained parts: in conſequence of which ariſe moſt ſharp pains, inflammation, difficulty of breathing, coughs, ulcers, immobility, and many other dangerous ſymptoms.

When the *rib* is luxated either upwards or downwards, in order to replace it conveniently, the patient is to be laid on his belly upon a table, and the ſurgeon muſt endeavour to reduce the luxated bone to its right place with his hands; or the arm of the diſordered ſide may be ſuſpended over a gate or ladder; and while the *ribs* are thus ſtretched up from each other, the heads of ſuch as are luxated may be puſhed into their former ſeat.

Thoſe luxations, where the heads of the *ribs* are found to be thruſt inwards into the cavity of the thorax, are much the moſt difficult to be reduced, becauſe neither the hand, nor any other inſtrument can be applied internally, to aſſiſt and direct the bone in the operation. In this caſe it ſeems proper to lay the patient on his belly, over ſome gibbous or cylindric body, and move the forepart of the *rib* inwards toward the back, ſhaking it ſometimes; for thus it ſometimes happens, that the head of the luxated *rib* ſlips into its former place. But if this method of cure will not avail, we have no remedy left but inciſion, and endeavouring to replace the luxated head of the *rib* by the fingers, plyers, or little hooks. In the mean time, where the ſymptoms are not very urgent, and the heads of the *ribs* but little diſplaced, it is much more adviſeable to have recourſe to none of theſe means, becauſe there are ſeveral inſtances where the luxated *ribs* have ſafely retained their diſlocated ſtations; but above all, care muſt be taken to lay on a compreſs, dipped in warm ſpirit of wine upon the part, and retain it on by the napkin and ſcapulary bandage. *Heiſter*, Surg. p. 157.

Fractured Ribs. Sometimes the *ribs* are only fiſſured in ſuch a manner, that the external or internal part of them are only hurt, without their being removed out of their place. This is uſually attended by no bad accident, and the bone frequently grows together again of itſelf, without the accident's being diſcovered. But if the whole *rib* be fractured, and ſome part of it removed out of its place, it is a more dangerous caſe: for the coſtal muſcles, and the pleura, that lines the internal cavity of the thorax, will be much diſturbed by the fragments of the bone.

When a *rib* is fractured, it projects either externally or internally in the form of a broken arch; when it projects externally the ſymptoms are uſually much milder; but when it is drove inward the caſe is uſually much worſe, eſpecially if any vein or artery be divided by it, ſo as to let blood run into the cavity of the thorax: in conſequence of which there follow prickings, inflammation, difficult reſpiration, coughs, fevers, ſpitting of blood, ſuppuration, extravaſation of blood, and other bad ſymptoms, particularly if any of the viſcera are hurt at the ſame time.

In order to replace fractured *ribs*, it is neceſſary firſt to enquire whether they project internally or externally; when externally, the patient is to be placed upon a high table, and the ſeparated bones muſt be gently forced by the fingers into their places; the proper compreſſes, dipped in ſpirit of wine, muſt be laid on, and then covered with ſlips of paſtboard, or ſplints, and the circular bandage, or napkin and ſcapulary. But when the ſplinters are thruſt inward, while the patient retains a deep breath; both ſides of the bone muſt be compreſſed with the hands, and agitated till they are properly fixed. When they are replaced, the paſtboard muſt not be applied in this caſe, but only the bandage drawn a little leſs tight; by theſe means, fractures of this kind are uſually cured in three or four weeks. Ibid. p. 123.

Ribs *of fiſhes*. There is a very great variety in the ſhape, and other peculiarities of the *ribs of fiſhes*. They are in ſome ſmooth and flatted ſideways, as in the cyprini. In others they are rounded, as in the cotti and gadi. In the cyprini

cyprini the feveral fpecies have from thirteen to nineteen *ribs* on a fide, and the vertebræ are from thirty-feven to forty nine in number, differing greatly in number in the feveral fpecies of the fame genus. The *ribs*, in many fifh, adhere to the vertebræ, by means of cartilages, and feem only continued parts of them; but in others they are free, and loofe, and do not fo much as touch the vertebræ. We find inftances of the firft fort of ftructure in the cyprini, falmons, &c. and of the other in the pearch, the gadi, and the pleuronectæ. In the fpinofe fifhes, the laft vertebra always is terminated by a pair of broad apophyfes placed perpendicularly, and touching one another, and by means of cartilages thefe are fixed to the bones of the tail. *Artedi*, ichthyolog.

RIBS, among jewellers, the lines, or ridges, which diftinguifh the feveral parts of the work, both of brilliants and rofes. *Jeffries* on Diamonds.

RICA, among the Romans, a veil with which the ladies covered their heads. *Danet*, in voc.

RICCIA, in botany, the name of a genus of plants of the lichen clafs, or, according to Linnæus, of the algæ: the characters of this genus are thefe. The male flower ftands on the furface of the leaf, without a pedicle, and has neither cup nor petals, nor even ftamina, but is a fimple anthera or apex, of a tapering form, but truncated, and opening at the top when ripe. The female flower grows fometimes on the fame, fometimes on different plants. It has fcarce any cup, and no petals, but is loaded with a globofe fruit, having only one cell, which contains a vaft number of feeds. *Linnæi* Gen. Pl. p. 507. *Michel.* Nov. Gen. p. 57.

RICE (*Cycl.*)—The Chinefe water their *rice* fields by means of moveable mills, placed as occafion requires, upon any part of the banks of a river. The water is raifed in buckets to a proper height, and afterwards conveyed in channels to the deftined places. *Boyle*'s Works abr. Vol. 1. p. 108.

RICERCATA, in the Italian mufic. See RESEARCH, *Cycl.*

RICHARDIA, in botany, the name of a genus of plants, the characters of which are thefe. The cup confifts of one leaf, divided into fix parts, and is erect and pointed, and of about half the length of the flower. The flower is monopetalous, and of a cylindric funnel like fhape, the edge is divided into fix fegments. The ftamina are fix filaments, fo fhort as to be fcarce obfervable. The antheræ are roundifh and fmall, and ftand in the notches of the flower. The germen of the piftil ftands beneath the cup. The ftyle is capillary, of the length of the ftamina, and divided into three parts at the top. The ftigmata are obtufe. The feeds ftand naked, and are three in number; they are roundifh, but angular, and are broad at the upper part and gibbous. *Linnæi* Gen. Pl. p. 150.

RICINOCARPODENDRON, in botany, the name of a genus of plants, eftablifhed by Dr. Ammam, the characters of which are thefe. The flower is of the rofaceous kind, confifting of three petals, difpofed in a circular order, in the center of which there arifes a large and open tube, through which fhoots up the piftil, which grows at the bottom of the cup. This piftil finally becomes a trigonal fruit, divided into three cells within, and containing each one feed in a rough coat.

The leaves of this tree fomewhat refemble thofe of the afh, being compofed of three or four pairs of fmaller leaves joined to a middle rib; thefe are not ferrated, and terminate in a fharp point. The flowers grow at the alæ of the leaves, they are white, and are difpofed in lax fpikes. The fruit is green at firft, afterwards it becomes of a yellowifh red, and finally fcarlet. It is of the bignefs of a walnut, and in fhape much refembles the fruit of the ricinus. The covering of the feeds is black on the outfide and red within, and each feed is divided into two lobes. When ripe, the fruit burfts, and the feeds fall out. It is a native of the Eaft Indies. Act. Petropol. Vol. 8. p. 214.

The word is compounded of *ricinus*, *καρπὸς*, *fructus*, and *δένδρον*, *arbor*. See RICINUS.

RICINOIDES, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the rofaceous kind, being compofed of feveral petals arranged in a circular form, and placed in a many leaved cup; thefe, however, are male, or barren flowers; for the embryo fruits appear on other parts of the plant; thefe are contained in a cup, and finally become each a fruit, which is fiffile into three capfules, containing oblong feeds.

The fpecies of *ricinoides* enumerated by Mr. Tournefort are thefe. 1. The common French *ricinoides*, from which the French turnfole is prepared, and which is called by many authors heliotropium, or turnfole. 2. The American arborefcent *ricinoides* with divided leaves. 3. The cotton leaved American *ricinoides*. 4. The American *ricinoides* with ftave's acre leaves. 5. The hairy poplar leaved American *ricinoides*. 6. The chefnut leaved American *ricinoides*. 7. The fhrubby marfh mallow leaved and American *ricinoides*. 8. The mullein leaved American *ricinoides*. 9. The æleagnus leaved American *ricinoides*, 10. The citron leaved American tree *ricinoides* with filvery duft. *Tourn.* Inft. p. 656. See HELIOTROPIUM.

RICINUS, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the apetalous kind, confifting only of a number of ftamina which arife from a cup. Thefe flowers are barren, and the embryo-fruits grow on other parts of the plants; thefe become at length each a trigonal fruit, compofed of three capfules, containing feeds covered with a hard rind.

The fpecies of *ricinus* enumerated by Mr. Tournefort are thefe. 1. The common *ricinus* or palma chrifti. 2. The great American *ricinus* with green ftalks. 3. The great American *ricinus* with red jointed ftalks. 4. The fmall American *ricinus*. 5. The *ricinus* of Ceylon with deeply divided leaves. See Tab. 1. of Botany, Clafs 15.

The feeds of almoft all the fpecies of this plant are very violent emetics and cathartics. Some have ventured to give them in fmall dofes, in dropfies, but the practice is hardly juftifiable.

RICKETS (*Cycl.*)—*Rickety* children have larger livers, and lefs hearts, and lefs blood, than children in health, from too full and too grofs a diet, and too little exercife; and they have larger livers than children in health, from the livers always increafing in weight, when the weight of the heart and quantity of blood leffen. See HEART and LIVER.

Dr. Hahn, in a letter on the cyrtonofus, or *rickets*, which is commonly thought to be a modern difeafe; quotes Hippocrates, and feveral other antient writers, as treating of it. Med. Eff. Edin.

RIDE (*Cycl.*)—To RIDE *land-locked*, at fea. See the article LAND-*locked*.

To RIDE *by the ftoppers*, at fea. See the article STOPPERS.

RIDGES (*Cycl.*)—The method of plowing land up into *ridges*, is a particular fort of tillage. The chief ufe of it confifts in the alteration it makes in the degrees of heat and moifture; thefe being two of the grand requifites of vegetation, and very different degrees of them being requifite to the different forts of plants. Thofe plants commonly fown in our fields require a moderate degree of both, not being able to live upon the fides of perpendicular walls in hot countries, nor under the water in cold ones, neither are they amphibious; but they muft have a furface of earth, not covered, nor much foaked with water, which deprives them of a proper degree of heat, and caufes them to languifh. In this cafe they look weak, and their leaves yellowifh. They ceafe growing; and, in fine, die in a weak and very bad ftate.

The only way to cure the land of giving this difeafe to plants, is to lay it up in *ridges*, that the water may fall off, and run into the furrows below, from whence it may be conveyed by drains and ditches into fome river, or otherways carried wholly off from the land.

The more any foil is filled with water the lefs heat it will have. The two forts of land moft liable to be overglutted with water are hills, the upper ftratum of mould in which lies on clay; and generally, all deep and ftrong lands. Hills are made wet and fpewy, by the wet that falls in rains, dews, and mifts; and this wet not being able to fink through the clay, in thefe foils, runs down between it and the mould; but extending itfelf through the mould all the way, and making it continually wafhy. The plowing this fort of land in *ridges*, made from the higher to the lower part of the field, is of no benefit; for the water will prefs from below upwards in thefe *ridges*, being forced by the addition of frefh fupplies above.

There are two methods of draining a hill ground like this. The one is to dig feveral deep trenches crofs-wife, or horizontally on the fides of the hill: let thefe be nearly filled up with fhores, and the furface covered in the common method: the wet will be received into thefe in all parts, and difcharged at the ends; and the plow will go over the ftones, without ftriking through the depth of earth that covers them. Thus the land will be dried for a time; but, as thefe channels fill up with earth, between the ftones, they become of no ufe, and the expence of making new ones is very great.

The other way is to plow the land in *ridges* almoft horizontally, and then the furrows between them are fo many drains, carrying off the water at their lower ends; if the plow is made to ftrike a few inches deep into the clay, and the ends of the furrows are no higher than the other parts: every furrow will be a drain to every *ridge*, and the land of the *ridges* will be kept dry. If there were no other manner of plowing the *ridges*, on the fides of hills, than there is in the plain lands, this method of having open furrows, or drains, on declivities, would be impracticable; becaufe the plow could not turn up the furrows againft the hill and againft the *ridge* alfo, from the lower fide of it. But the eafy remedy againft this inconvenience, is to plow fuch *ridges* in pairs, without throwing any earth into the trenches, and then the *ridges* will be plain at top, and the rain water will run fpeedily downward to the next trench, and thence to the head land, and fo out of the field. Thefe trenches will be made, as well as kept always open by plowing in pairs; and this is abundantly more eafy than the way of plowing *ridges* fingly.

Every time of plowing the *ridges* muft be changed as to the pairs;

pairs; so that the furrow, which had two *ridges*, or lands, turned towards it one time, must have two turned from it the next time; and this method keeps the surfaces of all the *ridges* or lands pretty nearly even. This, however, cannot be done on a hill, whose declivity is so great, that the plow is not able to turn a furrow against it; but, in this case, perhaps, it may be sufficient to plow the *ridges* obliquely enough for the furrows to be turned both ways.

This plowing in an horizontal manner, on hills, is the best of all others; but our farmers are not to be easily brought into it, though they see thin lands of this kind ruined for want of it; their reasons for not doing it, are, that it would prevent the supposed benefit of cross plowing; and that they lose more ground by having more furrows between the *ridges*, than when they lay their lands flat; where the lands are made much larger than the round *ridges* can conveniently be. But these are in reality very erroneous, as well as mischievous opinions; for more mischief than good is done by cross-plowing in general; and instead of any real loss of land by *ridges*, the true state of the case is, that much ground is gained by it; that is, the surface of the earth is increased in quantity; for if a flat piece be plowed into *ridges*, and if in earth sixteen feet breadth, there be an empty furrow of two feet; and yet, by the height and roundness of the *ridges*, they have eighteen feet of surface, capable of producing corn equally with eighteen feet, while the piece was flat; there is then, instead of any loss, one eighth part of profitable ground, gained by the altering the piece from a level into a *ridge*.

RIDGES, in the manege, are the wrinkles, or risings of flesh in the roof of a horse's mouth, which run across from one side of the jaw to the other, like fleshy *ridges*, with interjacent furrows, or sinking cavities. It is upon the third or fourth *ridge* that we give the stroke with the horn, in order to bleed a horse whose mouth is overheated. See HORN.

RIDING (*Cycl.*)—RIDING *cast*, in husbandry, a term used by the farmers for a particular method of sowing their grounds, by making two *casts* upon a ground at the same time. This is not much used, but it is a quicker way than the double *cast*, which is the method now most used. *Plot's* Oxfordshire, p. 251.

RIDING *clerk*, one of the six clerks in chancery; who, in his turn, for one year, keeps the controlment books of all grants that pass the great seal. *Blount*.

RIEMLING, in zoology, a name given by several to the small fresh water fish, called by the Latins *phoxinus*, and vulgarly the *pink*. *Willughby's* Hist. Pisc. p. 267.

RINÆUS *musculus*, the name of a muscle mentioned by Douglass, which he also calls *nasalis*: it arises fleshy from the extremity of the os nasi, and adjacent parts of the os maxillare, and is inserted into all the cartilages of the alæ. Its use is to open and dilate the nostril, by pulling that part outwards.

RINAR, a word used by the chemists to express filings of any thing.

RINEUS *marinus*, a name given by some botanical writers to the *crithmum*, or *samphire*, a sea plant used as a pickle. *Ger.* Emac. Ind. 2.

RING, (*Cycl.*) in angling, an instrument intended to free the hook, when accidentally entangled among weeds. It is a circular piece of lead, of about six inches round, and is fastened to a long packthread when it is to be used. It is slipped over the end of the angling rod, and let down into the water where the line conducts it to the hook; the rod and line have then no farther business; but the hook is endeavoured to be disengaged by the pulling this ring backwards and forwards by the string which is fastened to it; the hook is generally freed from the weed by this means; but if not, and nothing but the breaking of the tackle will do, the breach is made in this manner near the hook; whereas if done without this ring, it might have happened in some other part of the line, or the rod itself might have been destroyed by it.

RINGS *of flies*, in natural history, the several rounds, or circular portions, of which the bodies of these and other insects are composed.

In the *fly* kind these are crustaceous or cartilaginous, and consequently of a matter little capable of extension; many actions of these insects require, however, that their bodies, or a part at least of their bodies, should be able to inflate or distend, and contract their size occasionally. Were every *ring* of the body one entire scale, or shelly substance, these changes could not be easily effected; nature has therefore so provided, that the tender bodies of these little creatures are sufficiently defended, and yet all the necessary motions may be performed.

In many flies each *ring* is indeed one entire scale; but, in this case, it makes a circle round the body of the creature, whose ends do not join, but have a furrow between them, and running the whole length of the body; this furrow is placed under the belly, and is of different sizes in the different species. It is very narrow in the great blue fly, and much broader in many smaller species. This furrow is filled with a matter merely membranaceous, or in other species, with a series of small moveable scales, ranged endwise one to another, and in number exactly equal to the *rings* of the body; and on each side, between these scales and the extremities of the several *rings*, there is a small membranaceous substance, which is capable of extending and giving way, as the inflation or contraction of the body on different occasions may require. *Reaumur's* Hist. Inf. Vol. 4. p. 256.

Other species of flies have to every *ring* two scaly arches, which differ a little in bigness; the one covering the back, and the other the belly of the creature; these arches are joined on each side by a muscular membrane. When the body is in its state of smallest extension, and is flatted, or contracted, this membrane is seen to make several foldings laid closely over one another, and making the whole take up but a very small space; and, in this case, the superior scaly arch seems immediately to touch, and be joined to the inferior: but when the creature inflates, and extends its body, the membrane opens from its several foldings, and gives room for a vast increase in diameter; and the extremities of the two ranges of scales separate to a very considerable distance from one another. The flies produced from the rat tailed water worms, give us an instance of this mechanism. In other flies there are none of these membranes, nor furrows, but the body is composed of *rings* made up each of two single scales, one covering the back and the other the belly; but these, in the common state of the body of the creature, are laid a great way over one another, and are not fixed to that position, but can slide asunder as the creature distends itself; and in many species of insects these scales continue to cover each other in part, even when the body is distended to a very great degree. Bees, wasps, &c. are thus formed; and it is extremely necessary that they should be so, since they have frequent combats with one another: if they were not thus armed, the strokes of their stings would easily find entrance through such membranaceous commissures as are found in other flies, and would prove fatal. Ibid. p. 257.

RING *of saturn*, in astronomy, an opake, solid, circular arch or plane, like the horizon of a globe, which entirely encompasses, but no where touches the planet. See the article SATURN, *Cycl.*

RING *dove*, in zoology, the name of a bird of the pigeon kind, called by Aldrovand and other authors the *palumbus torquatus*, and by the Greeks *phassa*. Its beak is yellow, its feet naked and red, its legs feathered almost down to the feet. The upper part of its neck has a very regular and beautiful white circle, from which the bird has its name; and its whole neck, above and below this, is beautifully variegated with changes of colours, according as it is opposed to the light. Its head and back are of a dusky blue grey, and its throat and breast of a grey mixed with purple, its belly of a plain grey. The colours are all deeper, and more lively in the male than female. It seldom flies single, but in large flocks, and builds on trees; its food is ivy berries and other vegetable matter. See Tab. of Birds, N° 27. *Ray's* Orn. p. 185.

RING *head*, an engine used in stretching of cloth. 43 Eliz. c. 10. *Blount*, *Cowel*.

RING-*scalpel*. We have a description and figure of a *ring-scalpel*, for assisting the delivery of women in child-birth, by Dr. Thomas Simson, in the Medical Essays of Edinburgh, Vol. 5. Art. 39.

RING-*tail*, in zoology, the English name for the female of the *subbuteo*; the male and female in this species, differing so much in colour, as to be called by two names; the male being called the *henharrier*. See the article HENHARRIER.

The *ring-tail*, or female *subbuteo*, is a moderately large bird. It has a sort of *ring*, or chain of feathers, round the back part of its head, reaching to its chin on each side, which stand erect, and are brown in the middle, and of a reddish white at the edges, and make a sort of crown which surrounds the head; and from this there hang down a naked skin, which covers the ears. It has a white spot on each side under the eyes; its breast and belly are of a tawny white, with long brownish streaks; and the middle of its throat is brownish; its back and wings are of a dusky ferruginous colour; its tail variegated with transverse streaks of black and tawny. The upper part of the beak is covered with a yellow skin. Its legs are yellow, and the inside of its mouth is black. It feeds on small birds, and its eggs are of a reddish hue, with very little clear white appearing in them *Ray's* Ornitholog. p. 40.

RIONDO, in zoology, a name used by some for the fish more commonly called *aper*, a small fish, of the shape of the faber or doree, caught in the Mediterranean. *Ray's* Ichthyogr. p. 296. See the article APER.

RIPIENO, in the Italian music, is used in pieces of music in parts, to distinguish those that play to fill up, from those that play throughout the piece. There are, says Mr. Brossard, two kinds of the *ripieno*: one plays the part of the little chorus exactly, and does not, therefore, increase the harmony or number of parts. What is to be played by all the musicians is marked with the words *tutti* or *omnes*. This sort of *ripieno* is found in almost all compositions. The other sort is much better, a different part being played, whereby

whereby the number of parts is increased, and the harmony made fuller. Thus in pieces where in strictness two trebles, and bass, and thorough bass are sufficient, because these parts are disposed in such a manner, as that their harmony is complete when played all together; yet, in order to render the piece more perfect, and to give it more grandeur, a counter tenor, tenor, and often two violins are added, whose parts are entirely different from the other; and the harmony then has seven parts instead of three, and is consequently more complete and full. The parts thus added are properly called *ripieni*. *Brossard.*

RIPIERS, *ripiarii*, in our old writers, those that bring fish from the sea coast to the inner parts of the lands. Camb. Brit. 234. *Blount, Cowel.*

They were thus called a *fiscella, qua in devehendis piscibus utuntur, anglice* a rip.

RIPOSTE, in the manege, is the vindictive motion of a horse that answers the spur with a kick of his foot.

RIPPERS, in the wire works, are the people who attend in the mills, take the prepared small rods of iron, and work at the barrels where they are drawn into wire. *Ray's* English words, p. 133.

RISCUS, among the Romans, sometimes signifies a chest or trunk covered with skins; sometimes it is used for a hamper, made of twigs or rushes to hold lint; and sometimes for a hollow place in the wall of a house, used likewise for holding lint, or the like. *Pitisc.* in voc.

RISENTITO, in the Italian music, is a brisk, lively, or expressive manner of playing.

RISIGALLUM, in the materia medica, a substance of a red colour, generally placed among the kinds of arsenic or orpiment of the antients. Some of the later writers understand by it the sandarach, and others the factitious red arsenic; that it was looked upon to be poisonous is plain from Avisenna, who recommends it for killing rats, mice, and other vermin; and this seems to refer it to the factitious kind, or something of that sort, known in those times; for the native sandarach, does not stand in the rank of poisons with them, nor indeed is such.

Dioscorides seems to distinguish the red orpiment from sandarach, in that he says, it approaches to the sandarach in colour; he would never say that a thing was of the like colour with itself; and therefore it appears, that he knew two kinds of red substances, under the names of red orpiment and sandarach. Avisenna mentions a red, a yellow, and a green zarnicle. We find these writers called the lapis armenus by the same name zarnicle with the orpiment; and it is probable, that this author confounding the two different substances together, means real orpiment by the red and yellow, and a poor greenish blue lapis armenus by the green.

RISING (*Cycl.*)—RISING *timbers*, in a ship, are the hooks placed on her keel; and are so called, because as they rise in proportion, so her rake and her run rise on her flat floor by degrees.

RISORIUS *novus*, in anatomy, a name given by Santorini to a muscle, formed of that part of the *quadratus genæ*, which arises from the cheek.

RISVIGLIATO, in the Italian music, is used to signify, that after having played or sung a doleful and lamenting strain, a gay and lively air is to follow.

RITHER, or RIDER, in mining, is a stone or thin clift that lies in the vein; the ore sometimes runs on both sides it. Sometimes the *rither* is so thick, it parts the vein, and makes one vein two. *Houghton's* compl. Miner in the Explan. of the Terms.

RITUALES *libri*, among the antients. See ARUSPICI *libri*.

RIVERS (*Cycl.*)—It has been held by many, that all springs and *rivers* owe their origin to rains and dews; but there are some springs which cannot be accounted for on this principle, though others very well may. The intermitting springs, which flow violently in rainy seasons, and are dry in summer, are probably owing to rains; but there are some springs, which discharge more water annually, than all that falls in rain and dews in the neighbouring country. The great perennial springs at Willowbrig in Staffordshire is of this kind, and that of the Sorgne in France is much more eminently so; the *river* of that name, being, according to Gassendus, navigable up to the very springs which are its source.

But if such springs, as these, discharge too great a quantity of water for the supply of rains and dews; how is it possible, that such small supplies of water as these, can afford the constant currents of the larger *rivers?* The Volga alone, according to Ricciolus, pours forth as much water in a year's time into the Caspian Sea, as would suffice to drown the surface of the whole earth. The *river* of St. Lawrence, in the West Indies, pours forth nearly as much as this. If either of these *rivers* alone do, as has been affirmed, from calculations, discharge annually as much water, as falls in the same time in rains and mists upon the surface of the whole earth; from whence are all the rest to be supplied, according to the system of their all being made by brains; and particularly where is left the supply for the Rio de la Plata; which Ricciolus affirms to be larger than the Nile, the Ganges, and the Euphrates put together? its mouth being ninety miles wide, and running with that violence into the sea, that it makes it fresh for two hundred miles together. These, and the other *rivers* of the several parts of the globe, upon a very moderate calculation, discharge at least five hundred times as much water into the sea, as falls upon the whole surface of the earth, in rains, mists, dews, snows, &c. in a like space of time.

As it is evident, therefore, that these cannot be supplied by rains, so neither is it possible that the several hot springs, and the salt springs can be supplied that way: the origin of springs also in places where there falls little or no rain, and where the conservatories must needs be too small to contain a supply, are great proofs that rain and mists are not the origin of springs, at least not in all places. The isles of Mago, Rotunda, and the Strophades, and the rock whereon the maiden tower stands in the Thracian Bosphorus, cannot be supplied with, or retain a sufficiency of rain water to supply constant springs, yet such are always found running there.

It cannot be otherwise but that there are subterranean communications between the sea and the sources of fountains, *rivers*, and the larger springs, by which these are supplied; and there are certainly charybdes which swallow the sea for these purposes; and when these happen to be stopped, the largest *rivers* have been dried up, and wholly ceased to run for a considerable time: this we have accounts in history has happened to the Thames, the Trent, and Medway in England; the Elve, the Motala, and Gulspang in Sweden, and other *rivers* in other countries. If, on the other hand, these charybdes happen to be too open, fresh water springs depending upon them will become salt. This we have instances of in history also; and even so old a writer as Pliny has said, that this once happened in Caria near Neptune's Temple. *Plot.* de Origine Fontium. See PENUARIA.

It is pretended, by some writers of voyages, that there are two *rivers* in China, the Chiemo and Jo, both in the province of Hensi, the water of both which is so light that the smallest straw cannot swim in them, but sinks to the bottom; but we have no authentic testimony of this wonderful thing. *Redi's* Esperience.

RIVER *horse*, in zoology. See HIPPOPOTAMUS.

RIVET, in the manege, is the extremity of the nail that rests or leans upon the horn when you shoe a horse. See the articles NAIL and SHOE.

RIVINIA, in the Linnæan system of botany, a genus of plants, the characters of which are these. The cup is a perianthium, divided into four segments, of a different colour from the rest of the plant, and remaining till the seed ripens. Its segments are oblong, oval, and obtuse. It has no petals. The stamina are four filaments shorter than the calyx standing in pairs, and remaining with the cup; the antheræ are very small. The germen of the pistillum is large and roundish, the style is very short, and the stigma simple and obtuse. The fruit is a round berry, standing on the cup, the leaves of which are bent back; this berry contains only one cell, in which is contained one roundish, but flatted, rough seed. *Linnæus's* Gen. Plant. p. 52.

RIVOLGIMENTO, in the Italian music, is the placing a treble or upper part in the place of the bass, or any low part, or *vice versa*. This often happens in double counterpoint, where the treble serves for the bass, or the bass for the treble; and that in such a manner, that the harmony, though different, remains as correct after this change, as it was in the natural order of the parts.

RIZIUM, in botany, a name given by the antients to a peculiar kind of red root brought from Syria, and used by the Grecian women to paint their cheeks red.

The Latin writers, who have mentioned this, have called it *radicula*; and Pliny, who has more than once mentioned it, calls it *herba lanaria*, or *radix lanaria*. This, however, is a very great error, confounding it with the *struthium* of the Greeks. It is probable, that the *rizium* was no other than the *ancusa*, or *alkanet root*, which grows very plentifully in the countries from whence the Greeks had their *rizium*, and which will answer all the purposes for which they used it. See ANCUSA.

ROACH, (*Cycl.*) in ichthyology, the English name of a fish, called by the generality of authors the *rutilus* and *rubiculus*, by some the *rubellio*. It is a species of the *cyprinus*, according to the new system of Artedi. See the articles RUTILUS and CYPRINUS.

ROACHING *of alum*, one of the last processes used in the *alum* making, and is what renders it fit for the market.

After the *alum* liquor has been left four days in the cooler, and is sufficiently shot, they drain it out; and taking out the *alum*, they wash it in a cistern of *alum* water so strong, that it can scarce take up any more of that salt, but only cleanses it of its accidental foulnesses. After this washing the *alum* is put into large pans, and a quantity of water added to it. It is set over the fire to melt in this water and boil a little; then it is scooped into a great cask, where it is suffered to stand about ten days; and it is then fit for the market under the name of *roach alum*, or *roached alum*; the

liquor let out of the cooler is boiled up again, and shoots more *alum*.

ROAD *goose*, in zoology, the name of a small species of wild *goose*. See the article GOOSE.

ROAN, in the manege. A *roan* horse is one of a bay, sorrel, or black colour, with grey or white spots interspersed very thick: when this party-coloured coat is accompanied with a black head and black extremities, he is called a *roan* with a black-a-moor's head. And if the same mixture is predominant upon a deep sorrel, it is called claret *roan*.

ROASTING, in metallurgy, is the separation of volatile bodies, from those which are more fixed by the combined action of air, and fire; and is generally the first process in the separation of metals from their ores: it differs from sublimation only in this, that in this operation the volatile parts are dissipated, when resolved into vapours; whereas in that they are preserved.

Sulphur and arsenic are in this manner collected and preserved in the *roasting* of many ores; and sublimation made, as it were, occasionally in the process.

The separation of the volatile parts of bodies, from the more fixed is, however, in many cases very difficult, and much nicety is required in the conducting this operation; this is the case, for instance, when the whole compound body melts in almost the same degree of fire that is necessary to raise, and dissipate the volatile parts in the air; in such cases, care must be taken, first previously to pound a little the body to be *roasted*, that its surface contiguous to the air may be increased in extent. A gentle fire is also necessary on such occasions, and a very free access of the air, which is the vehicle of these vapours. When the body in the *roasting* grows on these occasions into large lumps or clots, the surface of it must be restored to the necessary extent, by repeated poundings, for it is necessary above all things, that the matter be kept extended and recent, and never collected into a heap.

Bodies the most refractory in the fire, are always the most easily *roasted*; for a great fire may be consequently kept up to such, nor need the operation be repeated so often. Care must always be taken, however, that while the volatile bodies are dissipating in the fire, they do not carry up with them something from the fixed ones also; for this is a disadvantageous accident, and too often happens, especially when a fire too violent is used in the beginning of the operation; to prevent this, it is sometimes necessary to add some fixing body to the mass. *Cramer's* Art of Foss. p. 189.

The business of *roasting* of ores of metals, as now usually practised, is subject to many inconveniences, which may be most of them easily remedied, and the whole business reduced to a few easy rules. 1. The *roasting* of ores should be always performed, without addition, when the ores are rich, or of itself merely of a metallic nature. But the additions of quicklime, potashes, iron filings, and the like, are necessary, when arsenical, antimonial and sulphureous matters are found to be mixed with the ores. 2. The fire is to be so regulated from the first, that only the lighter or more volatile sulphureous or arsenic fumes may fly off, otherwise the more metallic part would likewise go, and without some contrivance to catch it would be lost. The ore must, however, always feel the force of an open flame, otherwise the sulphur, arsenic, &c. will never be thoroughly dislodged. 3. The more these immature substances abound in ore, the gentler the fire should be at first; and when the greater part of the sulphureous matter is thus exhaled, the fire is then to be quickened. 4. Where such additions are used, as are not metalline, as lime, mud, pot-ash, &c. they ought always to be separated afterwards from the matter before the fusion, by washing. *Shaw's* Lectures, p. 251.

ROB, (*Cycl.*) in pharmacy, the inspissated juice of any substance, usually boiled up to the consistence of honey.

It is possible, that great improvements might be made, by introducing the use of this form among the malt distillers. The great inconvenience attending that art being, that the malt being of a large bulk, in proportion to its saccharine part, and requiring a large proportion of water to extract that saccharine part, many large vessels, such as mash tubs, coolers, fermenting backs, &c. are necessary; and the necessary labour on the subject is increased, and the commodity rendered dearer. The remedy of this should seem the introducing a new art subservient to that of the malt distiller, and confining itself to the boiling down of malt wort to a *rob*, so as to supply the malt stiller with his subject, in the same manner as the fine stillers are supplied with treacle by the sugar baker. By this means the business of the malt stiller would be reduced to a great degree of simplicity, and the spirit produced would be also much finer than at present, because the subject would come tolerably refined to his hands, and purged of its gross, mealy and husky matter, which yields a disagreeable oil in distillation, and is also apt to burn to the still, and spoil the spirit. It is possible that a spirit purer and finer than that from treacle might this way be procured from malt prudently managed. Ib. p. 219.

ROBALO, in zoology, a name by which some have called the *camuri* an American sea fish of the *lupus marinus*, or basse kind. *Willughby's* Hist. Pisc. p. 272. See BASSE.

ROBBINS, in a ship, small lines which make the sail fast to the yards, being reeved into eylet holes in the sail under the head-rope for that purpose. The word is *make fast the Robbins*: for at sea they don't say *tie*, but make fast.

ROBERSMEN, or ROBERDSMEN, in our old writers, a sort of great thieves, mentioned in the statutes, 5 Ed. 3. c. 14. And in Rich. 2. c. 5. Sir Edward Coke says, that *Robin Hood* lived in the reign of Rich. 1. on the borders of England and Scotland by robbery, burning of houses, rapine and spoil, &c. And that these *roberdsmen* took their names from him. 3. Inst. 197. *Blount*, *Cowel*.

ROBIA HERBA, in Botany, a name given by Paulus Ægineta, and many others to a plant used in dying.

The near resemblance of the name to the word *rubia*, has made many conclude that it was the *rubia*, or madder which they meant by it, but they have taken care in their writings to distinguish it from that plant, and it is plainly the *genistella tinctoria*, or dyers weed, that they meant by the *robia herba*. They say it was used to dye yellow, and that it was also a custom to stain the hair with it.

These are the properties recorded of the *cymene* and *œcomenium* of the Greeks, and *lutum* or *lutea herba* of the Latins, which were names of the *genistella tinctoria*. Pliny says, that the *lutum* had leaves like flax and flowers like broom, which is exactly the case with the *genistella tinctoria*, but by no means agrees with the glastum or woad.

ROBINIA, in botany, the name of a genus of plants, called *pseudo-acacia* by Tournefort, and the generality of authors. The characters are these; the perianthium is small and one leaved, it is divided into four segments at the end, the three under segments are very narrow, but the upper one four times as broad, tho' of the same length with the rest, and is slightly emarginated; the flower is of the papilionaceous kind. The vexillum is large, round and obtuse. The alæ are of an oblong oval figure, and stand free, having a very short obtuse appendage: the carina is nearly of a semiorbicular figure, it it compressed, obtuse and of the same length with the alæ. The stamina are diadelphous filaments pointing upwards. The antheræ are roundish. The germen of the pistill is oblong and of a cylindric figure; the style is capillary and turns upwards, and the stigma is hairy and placed forward at the apex of the style. The fruit is a large and long pod of a compressed figure and somewhat gibbous; it contains a few kidney shaped seeds. *Linnæi* Gen. Pl. p. 349. *Tourn.* Inst. p. 417. *Rivin.* 4. 74.

ROCELLA, a kind of fucus or sea wrack found in the Mediterranean and other seas, and in some places used by the dyers for a purple colour, and called by the botanical writers, in general, *alga tinctoria*. *Casp. Bauhin.* Pin. p. 365.

ROCHET, the name given to a fish, otherwise called *cuculus* and *red gurnard*. See CUCULUS and GURNARD.

ROCHETTA, in the glass trade, another name for polverine. See the article POLVERINE.

ROCKS (*Cycl.*)—These are generally supposed great enemies to vegetation, and the people of Scotland have been deterred from cultivating many of their best lands, from an observation that they had a *rocky* bottom. This is however but a vulgar error among them, for *rocks* of a proper kind and properly disposed, as very many of theirs are, fertilize and are beneficial to the land, not hurtful.

In many parts of England we see gardens the most beautiful that can be imagined, both in regard to flowers and excellent plants, on a soil where the bottom is a hard *rock*, and the earthy covering not more than a foot or thereabout in depth. In some of these, all the disadvantages the Scotch complain of take place, and yet the gardens are fruitful, many of them having lofty hills on the south side; the declivity due north, and the *rock* perfectly bare next the walls on the north side.

The north sides of these hills in this very aspect, only with the *rock* covered with two or three foot of earth make very good hop gardens, producing a vast quantity of a very valuable commodity at a small expence; and it is remarkable that those gardens, which stand in this exposure, instead of being subject to particular evils, often escape those blasts and other mischiefs which affect the plantations of the same kind on the south side of the hills. It might be a very valuable article of trade, if the bleak hills of Scotland, or those of some of our northern plantations in America, could be made thus fruitful in so useful a commodity, and there seems only the want of a proper trial.

Another extremely valuable plant that might be raised on these barren *rocky* places, as they are generally supposed to be, is flax, in places where the descent is too steep for ploughing in the common way. It has been proved that a hand plough with a stem of ash of about seven feet long, and a plate on each side near the end to turn the turf, a coulter to be let out shorter or longer to four or five inches deep to cut the earth up as deep as it lies upon the *rock*, and an iron wheel, may be managed with ease and conveniency by two people, and will prepare ground for producing large crops of the finest flax. The best sort of flax seed of Flanders sown on this sort of ground succeeds so well, that if brought into

into general ufe it might give the only advantage that is at prefent wanting to the Scotch holland manufactory, and make it excell that of all the world befide. The northern American colonies might alfo furnifh us with the fame fort of flax raifed at a fmaller expence than almoft any other vegetable commodity, and coming to a fure market and at a very confiderable price.

Agriculture in Scotland is too much neglected to the great impoverifhing of the country, and the diftrefs of a numerous poor, for whom it would find conftant employment. It is not yet known whether many of the moft valuable plants for medicinal and mechanic ufes will not profper as well there, as where there are immenfe fums made by the raifing them; and the owners of lands would do well in this fcheme to try the effect of liquorice, madder, woad and the like plants on their grounds. Wherever the ground is deep enough, it is pretty certain that madder and liquorice would flourifh, and the laft of thefe needs fo little culture, that if once planted it may almoft be left to it felf. The *rocky* bottoms of lands, not too bleak, may alfo fucceed very well with faffron, which is one of the moft profitable plants that can be cultivated. Phil. Tranf. N° 109.

ROCK-*cryftal*, otherwife called *fprig cryftal*, in natural hiftory, a name given to the third order of *cryftals* from their being affixed to a *rock*, or other folid body.

This kind of *cryftal* is the moft common of all others, and is what the generality of authors defcribe under the name of *cryftal of the fhops*, being that kept for medicinal purpofes. See the article CRYSTAL.

The cleareft, pureft, and moft tranfparent that can be had, ought to be chofen; and to prove its genuinenefs, it may be tried with aqua fortis, true *cryftal* making no effervefcence with that menftruum. *Hill*, Hift. Mat. Med. p. 280.

ROCK-*fifh*, a common englifh name for the *gobius marinus* or fea gudgeon. *Willughby*'s Hift. Pifc. p. 207. See GOGET.

ROCK-*oil*, See the article PETROLEUM.

ROCK-*falt*, See the article *rock* SALT.

ROD (*Cycl.*)—ROD, in the manege, called in french *gaule*, is a fwitch held by the horfeman in his right hand, partly to reprefent a fword, and partly to conduct the horfe, and fecond the effects of the hand and heels.

Golden-ROD, in botany. See GOLDEN *rod*.

ROGATORES, among the Romans, thofe who in the *comitia centuriata* brought the cheft into which the people threw the ballots containing their votes. *Pitifc* in voc.

ROHEL, a word ufed by fome authors as the name for dragons blood.

ROLLER (*Cycl.*)—ROLLER, in zoology, the common name of a bird of the mag-pie kind, called *garrulus argentoratenfis* by authors, and fufpected to be the fame with the bird defcribed by Gefner under the name of the *blue crow*, *cornix cærulea*, and by Aldrovand under the name of *pica marina*. Its beak is black and long, fomewhat crooked at the end, otherwife like that of the common mag-pie; its eyes are of a greyifh hazel colour, and near them are two tubercles bare of feathers. Its rump and part of its wing feathers are of a fine blue, like the ultramarine colours ufed in painting; the middle of its back is of a reddifh brown, and the head is of a bluifh green, and its breaft and belly are of a whitifh blue or dove colour. It is brought to market in Italy and fome other places. See Tab. of Birds, N° 10. *Ray*'s Orn. p. 89.

ROLLER, in gunnery, a round piece of wood of about nine inches diameter, and four foot long, which ferves in moving mortars from one place to another when near. This is done by raifing the fore part of the bed fo high that a *roller* may be laid under it; then pufhing the bed forwards, and laying another in its way, and another before that and fo on, the mortar is eafily moved.

ROLLUS *aquaticus*, in zoology, the name given by authors to the *water rail*, a bird of the gallinula kind, called by fome *ortygometra*, and by others *gallinula chloropus altera*, or a different fpecies of the common green legged moorhen. It is very like the common moorhen but fmaller; its head is fmall; its body flatted, and its feet neither webbed nor enlarged by membranes, tho' it fwims on the water; its beak is like that of the ruff or avis pugnax, about two fingers breadth long and flatted fideways. It has a fmall bald fpot on its forehead, which is roundifh and black; its whole upper part is of a mixed colour of black and a brownifh yellow; the middle of all the feathers being black, and the fides of a dufky yellow. Its throat is of a greyifh red, its breaft is of a dead blue with a longitudinal white line in the middle; its belly is reddifh, and the lower part of its tail white; its legs are very robuft and ftrong, and it runs very nimbly; it is common about the fides of waters, and is a very well tafted bird. *Ray*'s Ornitholog. p. 234.

ROMAIN, in hufbandry, the name of a plant cultivated in the fields in many parts of the world, particulary in France, and called by our farmers *french vetches* or *french tares*; it is an annual plant but a very quick grower, and is extremely good food for cattle, particularly for horfes: they let thefe creatures feed on it all the fore part of the fummer, and then cut it for hay in Auguft or September. Its fhort continuance in the ground makes it lefs valuable than faint foin and clover, but it has this advantage over them, that it will grow on poor ground.

ROMAN (*Cycl.*)—ROMAN *Citizen*. See CITIZEN.

ROMPION, this kind of bell flower was formerly much efteemed in England for the fweet tafte of the roots, and univerfally cultivated in kitchen gardens; but we at prefent difregard it, tho' the French continue to be very fond of it. The feeds are to be fown in a bed of light dry earth in March, and in May the young plants will be of a fize to remove, or they may be left when fowed, only houghing them up to four inches diftance; being kept clean from weeds for the remaining part of the fummer, they will be fit for eating in the fucceeding winter.

RONDINE, in zoology, a name by which fome authors have called the *milvus*, or flying fifh. *Willughby*'s Hift. Pifc. p. 283. See the article MILVUS.

RONDINE-*pefce*, in zoology, a name by which fome have called the *hirundo pifcis* or *fwallow fifh*, called by others *mugil alatus*. *Willughby*'s Hift. Pifc. p. 233. See the article HIRUNDO *pifcis*.

ROOD (*Cycl.*)—In Scotland, the *rood* contains forty fquare falls. Tr. Pract. Geom. p. 82. See FALL.

ROOK, in zoology, a well known bird of the crow kind. See the article CORNIX.

Rooks are very deftructive of corn, efpecially of wheat, they fearch out the lands when it is fown, and watching them more carefully than the owners, they perceive when the feed firft begins to fhoot up its little blade; this is the time of their feeding on it, they will not be at the pains of fearching for it at random in the fown land, for that is more trouble than fo fmall a grain will requite them for; but as foon as thefe blades appear they are directed without lofs of time or pains by them to the places where the grains lie, and in three or four days time they will root up fuch vaft quantities of them that a good crop is often thus deftroyed in embryo. After a few days the wheat continuing to grow, its blades appear green above ground, and then the time of danger from thefe birds is over, for then the feeds are fo far robbed of their mealy matter that they are of no value to that bird, and it will no longer give itfelf the trouble to deftroy them.

Wheat that is fown fo early as to fhoot up its green blades before the harveft is all carried in, is in no danger from thefe birds, becaufe while it is in a ftate worth their fearching for, the fcattered corn in the harveft fields is eafier come at, and they feed wholly on this, neglecting the fown grain; but as this cannot always be done, the farmers to drive away thefe ravenous and mifchievous birds dig holes in the ground and ftick up the feathers of *rooks* in them, and hang up dead *rooks* on fticks in feveral parts of the fields; but all this is of very little ufe, for the living *rooks* will tear up the ground about the feathers, and under the dead ones, to fteal the feeds. A much better way than either is to tear feveral *rooks* to pieces and fcatter the pieces over the fields, but this lafts but a little while, for the kites and other birds of prey foon carry off the pieces and feed upon them. A gun is a good remedy while the perfon who has it is prefent; but as foon as he is gone they will return with redoubled vigour to the field and tear up every thing before them.

The beft remedy the farmer has is to watch well the time of the corn's being in the condition in which they feed upon it, and as this lafts only a few days, he fhould keep a boy in conftant pay to watch the field from day break till the dufk of the evening. Every time they fettle upon the ground or fly over it the boy is to hollow, and throw up a dead *rook* into the air; this will always make them rife, and by degrees they will be fo tired of this conftant difturbance, that they will feek out other places of preying, and will leave the ground even before the time of the corn's being unfit for them. The reafon of their rifing at the toffing up of their dead fellow creature is, that they are a bird extremely apprehenfive of danger, and they are always alarmed when one of their comerades rifes. They take this for the rifing of an out-bird, and all fly off at the fignal. *Tull*'s Horfehoing Hufhandry.

ROOM (*Cycl.*)—*Rooms* in houfes might be warmed by the fteam of boiling water conveyed in pipes along their walls. See Philof. Tranf. N°. 476. p. 370. feq.

The contrivance is a copper with a ftill head, and a lead or copper pipe fixed to this head, which conveys the hot fteam of the boiling water thro' the different *rooms* intended to be warmed.

ROOM, in a fhip, a place diftinguifhed by partitions, or bulk-heads, as the gun-*room*, bread-*room*, cook-*room*, powder-*room*, &c.

ROOT (*Cycl.*—The *roots* of plants, of all kinds, have great numbers of fibres, iffuing horizontally from them on all fides, and running a great way; but thefe feldom go deeper than about ten or twelve inches, the depth to which the earth is commonly ftirred in agriculture by the plough fpade. Some plants have all their *roots*, even the large ones, directed horizontally and fpreading in this manner; but of the others, even thofe which have top roots, or fuch as run perpendicularly

pendicularly down into the earth, the greater part have visible fibres running horizontally from them in great numbers, and even thofe which feem to have none, are not truly without them, they being only more fine and therefore lefs diftinguifhable by the eye.

The horizontal *roots* iffuing from the main body of the *root* feem to the eye to be fhort, and reach only a little way, but they in reality extend many times farther than they feem to do, often fpreading to the diftance of many yards, after their extream finenefs and earthy colour makes them imperceptible to the eye.

Mr. Tull has made experiments of this kind, and found that a turnep, which is a plant whofe root feems to have as few, and thofe as fhort fibres growing from its main ftem as any, yet has fuch as when the ground about it is properly moved by digging, extend to the diftance of fix feet every way. The diftance to which thefe fibres of the roots of plants extend may be difcovered by trials with falt; the common garden plants will not live, if their *roots* reach to a place where there is falt; therefore if feveral plants of the fame kind be planted in different parts of the fame bed of earth, and a trench dug round each at different diftances, and falt buried in this trench, it will be feen by the decaying of fome of thefe plants, and the thriving of others, according to the diftance at which the falt lies, which of them has reached it with their roots, and which have not; that is, which falt is placed at a diftance, to which the plants cannot extend their *roots*, and which is the fartheft place to which they do. If a furrow be cut in the ground of the depth of nine inches, and at the diftance of a yard from a turnep *root*, that *root* will extend its horizontal fibres to this diftance, at the depth of fix inches or thereabout from the furface; but when they are come thus far they will defcend perpendicularly below the level of the bottom of the furrow, and when they have paffed it, they will rife to the level of the others on the oppofite fide, and extend to the diftance of a yard beyond it. This could fcarce be conceived of a plant which feems to have fo few horizontal fibres as the turnep, but experiment has fhewn it to be a certain fact.

This is not peculiar to the turnep; for all other plants do it on occafion. The open mould being the natural foil for them to draw nourifhment from, if they defcend perpendicularly out of this to avoid expofing themfelves to the open air where there is a cut or ditch, as foon as they have paffed this, they always mount upwards again to enjoy the vegetable mould again at their proper depth: this is the reafon of what feems fo ftrange a thing in the turnep fibres as their rifing after they had paffed the furrow.

The *roots* of a common thorn hedge may be obferved to run horizontally in their natural direction, and if they come to a ditch they will defcend perpendicularly till lower than its bottom, and then running acrofs it, they will immediately mount again toward the furface, and extend themfelves horizontally at the depth of eight or ten inches to a great diftance: on opening the earth at five feet diftance from the ditch, the *roots* will be found tolerably large, and none of them reaching deeper than the common mould, which feldom is above a fpade deep.

Mr. Tull mentions a very extraordinary inftance of the fpreading of the *roots* of trees in that of a witch elm; a chalk pit contiguous to a barn, the area of which was about forty perch of ground, was made clean and fwept, fo that it could plainly be feen that there was no vegetable matter about it, any more than in the floor of the barn: ftraw was thrown from thence into the pit for cattle to lie on, and about three years after the pit was cleanfed, the dung made in it being taken up; the bottom of the pit, and the top of the chalk were at this time covered with *roots*, and thefe were found to come from a witch elm, of not more than five or fix yards in height, which was about five yards above the area of the pit, and eleven yards from it; fo that in three years the *roots* of this tree had extended themfelves to eight times the length of the body of the tree, beyond the extremity of the old *roots*, at eleven yards diftance from the bottom of the trench, whence the original *roots* proceed. The annual encreafe of the length of the *roots* in this cafe was about three times as much as the whole length of the tree.

The vegetable mould which lies ufually from the furface, to about a foot deep, being a proper place for the *roots* of trees, they will rife into it, tho' the unfkilful hand of man plant them deeper. Thus in an orchard where the trees are fet too deep, their *roots* all afcend till they come to a proper fcene of nourifhment; but if the ground be moift there is a difadvantage in this, for the *roots* paffing thro' a watery place are chilled, and the circulation retarded.

The generality of the world fuppofe, that the horizontal *roots* of plants are much fhorter than they really are, becaufe they fee that they are pretty taper near the *root*, and feem to come to a point very foon: by this obfervation they conclude that they diminifh on in the fame proportion that they do there, and confequently that they very foon come to an end. But by this means they calculate their length at lefs than one twentieth part of what it really is; for the truth is, that after the length of a few inches from the main *root*, they are not difcernibly taper, but pafs on in the fame bignefs to their very ends. This may be feen at any time in the *roots* of plants growing in water, and with care in the tracing them it may alfo be feen in thofe which grow in the earth; but the reafon why it is not commonly feen in thefe, is that they generally break off in the taking up about the part where they grow taper. Many plants which feem to have only large naked *roots* have thefe horizontal ones, which tho' fmall are branched out into many leffer fibres, and convey a great deal of nourifhment to the plant, and that from a great diftance. If a common carrot be taken up and examined, there will be found many fine fibres, like hairs growing from its fides: each of thefe examined with a microfcope, will be found to be a *root* not going taper, but all the way of the fame bignefs broken off at the end, and fending numerous fibres from its fides; all thefe are extended to fome length, and then appear broken off as the other; and it is very probable from what is known to be the cafe in the turneps, that this horizontal *root* is in its natural ftate extended four, five, or fix feet from the carrot, all the way of the fame length, and all the way fending out its lateral fhoots or fibres which run upwards and downwards the whole fpace of the ten or twelve inches of vegetable mould. If fo, from what a diftance every way, and by what an immenfe number of channels does this plant receive nourifhment?

The ufe of digging the earth to a great diftance every way from the *roots* of fuch plants as are defired to thrive well, is evident from this: for thefe tender *roots* which in an open mould will run to fo many feet diftance, are pinched up, and deftroyed when they come into a hard and undug earth. The advantage of having clear fpaces between plants cultivated for ufe, is alfo plain from this, fince they all have *roots*, tho' imperceptible to us, which occupy thofe fpaces, and draw nourifhment from them.

Many plants are of a fort of amphibious nature, and grow as well in water as on land; the perficaria falicis folio, or willow leaved arfmart, called when in the water, the long leaved pond-weed, is an inftance of this kind. This in the water and on the land makes fo different an appearance, that the old botanifts have taken it for two different plants. The *roots* of this, and of all other fuch plants, are much longer when they grow on land, than when in water.

The fecrets of vegetation as carried on by *roots*, and the ufes one part of the *root* is of to the other parts, are yet far from being underftood to perfection. We know indeed that all *roots* imbibe moifture from the earth, but it alfo appears, that they part with that moifture again in the form of water, as they received it without carrying it all up into the body of the plant on certain occafions. If a piece of flourifhing mint in a water glafs be fo contrived, that while the *roots* from one joint are all immerfed in water, thofe of an upper joint be received into a box, and laid all at one corner of it, and the box filled with fand dryed at the fire; after a nights ftanding, the water in the glafs will be found fenfibly decreafed, and the fand at that corner of the box where the *roots* of the mint are, will be found very wet, while all the reft remains dry. This water which has thus wetted the fand, muft have been received into the lower *roots*, and from thence conveyed to the upper ones, and they muft have again delivered it out into the fand, inftead of carrying it up into the body of the plant. Let a trough of earth be prepared of two feet in length, and let a ftrong fhoot of mint be fet in a glafs of water at each end of the trough, and while half the *roots* of each are placed in the water, let the other half be laid in the trough and covered with dry earth in powder; this dry earth will foon become moift, and the *roots* will fhoot out beyond its furface. Thefe are to be covered with foft earth as they appear, till the trough will hold no more; the whole trough will thus be foon filled with the *roots* of thefe two fhoots of mint, and thofe *roots* which rife to the furface, and are not covered, will be feen to bend down their points and enter the earth again.

Thefe mints grow greatly fafter than thofe which are planted either in water alone, or in water with earth in it; and the earth in the trough will always be found thoroughly moiftened, tho' no water is put to it, except what arifes from the lower *roots*, and is carried to thefe upper ones, which are placed in the earth. The quantity of water thus fent up by the lower *roots*, and thrown into the earth above by the upper ones, is more than a thoufand times the whole weight of the plants, and feems to have never mixed itfelf with the juices of the plant at all, but to have been evacuated pure water as it was received without ever going any higher than the upper *roots*.

The glaffes in thefe experiments need very frequent fupplies, a day or two being fufficient to drain them; but what is remarkable is, that if they are fuffered to be without water in the glaffes, they will not dry up or wither, but the *roots* below, as well as the plant above, will be kept

kept in a flourishing state for some time by the wet earth in the box. These experiments shew us a use in the several parts of the *roots* of plants, which providence has wisely allotted for the service of the whole, and which we can otherwise have no idea of. Every part of the *roots* of the same plant is thus found to be capable of supplying all the rest; and it is evident, that the several portions of the *roots* in the mint communicate one with another by means of vessels which serve only to carry water from the one to the other, without mixing it with the juices of the plant. Such vessels of communication there must have been between the two sets of *roots* of this mint, which must have passed thro' that part of the stalk of the plant, which was between the two joints, tho' several inches in length, and by these while one root was kept moist, the other was moistened by it, whether the upper one, or the lower one was in the moist place, and then the nourishment was carried up by both to the plant.

From this we see the great use of tap *roots* to plants, and understand the reason why the lucerne, saint-foin, and other plants which have long tap *roots* produce such numerous branches and succeed so well in dry seasons, when the shorter *rooted* plants are nearly destroyed. The earth at a great depth is always moist, and these tap *roots* penetrating to that depth imbibe that moisture, and send it up to the upper *roots*, which discharge it into the earth near the surface, as the upper *roots* of the mint do into the earth in the trough; and thence all the fibrillæ of the whole set of horizontal *roots* are supplied with a proper degree of moisture in the earth, where they run and grow almost as well as in moist weather. If this was not the case, the *roots* which are spread thro' the upper surface of the earth could be of no service to the plant in dry weather.

The stirring of the earth about the *roots* of plants has been a practice long used by our gardiners, who were well acquainted with the effects of it, tho' ignorant of its cause. The *roots* of plants send out horizontal fibres every way, and these send out fibrillæ on every side from them, which run thro' the whole upper stratum of vegetable mould: every time this mould is stirred, a great number of these fibres and fibrillæ are broken off, and the consequence of this is, that they encrease in number, several new *roots* always shooting out in the place of one that was broken off; and as the number of *roots* is the great means of the supply of a plant, every time the earth is stirred, that number, and consequently that supply is encreased.

There seems no danger of the plant's being surfeited by an over supply of nourishment this way; for we see nature has provided for a discharge of the abundant moisture by the other *roots*, as we find by the water discharged into the earth in the trough. It remains yet to try whether the fluid thus evacuated be pure water as received, or be altered into the nature of the plant. This cannot be easily determined by mint; but if a stronger flavoured plant, such as garlick, be set in water, and part of its *roots* placed in a bed of flower instead of earth, it will be soon seen whether the flower in this case be moistened as the earth in the other, and the tasting it will shew whether it be moistened with pure water, or with water altered to the taste and nature of the plant. *Tull's* Horsehoeing Husbandry.

Preparation of Roots, there are several ways of preparing *roots* for medicinal use in the eastern nations, which strongly alter them from their original form and appearance. An instance we have of this in the drug called *salep*, which is no other than the *root* of an orchis thus prepared. See the article Salep.

Other *roots* they also prepare in the same manner, or something like it; an instance of which we have in some of the oriental ginseng, which is clear and pellucid as a resin, and friable like one, retaining very little of the structure or appearance of the *root*. Kempfer gives the method by which the people in the east do this, and it may be well worth trying on some of our own *roots*.

The Chinese, this author informs us, give their ginseng its colour and transparence in this manner. They macerate the fresh *root* for three days in cold rice water, then expose it in close vessels, to the vapour of the same water; after which they carefully and leisurely dry it, and it becomes hard and brittle, of a brownish red colour, and as transparent as a resin.

All the ginseng of China is not of this sort, and it has been supposed by some, that such as was so, had assumed that appearance by age, as many of the more succulent *roots*, which have very small fibres, will become much less opake when perfectly dry, than they were at first; but experience shews that this is not the case, for many persons have kept the oriental ginseng a great many years, but it has never been known to assume that appearance. There is no doubt however, but that if the West Indian ginseng were treated in this manner, it would equal the prepared ginseng of the east: for the *roots* of some of our umbelliferous plants, particularly the skirret, may be made clear and transparent in this manner, by only boiling it in common water, and afterwards drying it in the open air. Mem. Acad. Scien. Par. 1740.

Flower-Roots. See the article Flower.

Root *of osteocolla*, a word used to express a sort of soft and rotten matter, on which the *osteocolla* of Germany is found in sandy grounds.

The workmen seek after the *osteocolla* by the direction of certain lumps, of a white marley matter, which they find lying on the sands; under this they always find a parcel of rotten vegetable matter, branching out from a main stem or trunk, at ten or twelve feet deep up to the surface; this rotten substance they call the *root of the osteocolla*; and they observe, that where the matter they seek after is not found round it at the time of their digging, they need only mark the place, and dig again a year afterwards, and they will find it formed in a perfect manner. The *osteocolla* found near Frankfort is all of this kind; and we find the holes in the center of all the pieces, through which this *root* had passed. It is so tender that it usually moulders away on the *osteocolla*, being exposed to the air; but sometimes they wash it out. Phil. Transf. N° 39. See Osteocolla.

It is not easy to conceive what this is, unless the remains of fossile branches of trees; but even then it is as difficult to account for the formation of the *osteocolla* about them, as there is none of it found concreted where they are not. We have a sort of *osteocolla* found with us in what we call petrifying springs; but as this is done in the water, it is easier to conceive how it becomes so pure, than how a soft and pappy substance found in the midst of a bed of sand, comes not to have some sand embodied in it.

Root, in mathematics (*Cycl.*)—The extraction of the *roots* of algebraic quantities, may be performed in a manner analogous to that used in arithmetic, for extracting the *roots* of numbers; and if the *root* cannot be accurately found, the process may be continued indefinitely, which will give a series. Thus the quantity $aa + xx$ being proposed, its square *root* thus extracted will be found to be,

$$a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \frac{5x^8}{128a^7} + \frac{7x^{10}}{256a^9} -, \&c.$$

See Newton's *Meth. of Fluxions & inf. series*, p. 4. of Mr. Colson's Edit.

But the extraction of *roots* may be abbreviated by that great author's *binomial theorem*, which he thus expresses in his letter to Oldenburgh.

$$\overline{P+PQ}^{\frac{m}{n}} = P^{\frac{m}{n}} + \frac{m}{n}AQ + \frac{m-n}{2n}BQ + \frac{m-2n}{3n}CQ + \frac{m-3n}{4n}DQ +, \&c.$$

Where $P + PQ$ signifies the quantity whose *roots* or dimension, or *root* of any dimension, is to be investigated. P, is the first term of the quantity; Q, the rest of the terms divided by the first. And $\frac{m}{n}$ is the index of the dimension or power of $P + PQ$, whether that denomination be a whole number, a fraction, affirmative or negative. Lastly, A, B, C, D, &c. represent the terms of the *root* as they are found; that is, A stands for the first term $P^{\frac{m}{n}}$, B for the second $\frac{m}{n}AQ$, &c. The use of the rule will appear by a few examples.

1. To find the square root of $cc + xx$; that is, $\sqrt{cc + xx}$, or $\overline{cc + xx}^{\frac{1}{2}}$. Substituting cc for P, $\frac{xx}{cc}$ for Q, 1 for m, 2 for n, $\overline{cc}^{\frac{1}{2}} = c = P^{\frac{m}{n}} = A$, &c. we shall have $\overline{cc + xx}^{\frac{1}{2}} = c + \frac{xx}{2c} - \frac{x^4}{8c^3} + \frac{x^6}{16c^5} -$, &c.

2. In like manner $\frac{N}{\sqrt[3]{y^2 - a^2 y}}$ or $N \times \overline{y^3 - a^2 y}^{-\frac{1}{3}}$ will be found equal to $N \times \frac{1}{y} + \frac{a^2}{3y^3} + \frac{2a^4}{9y^5} + \frac{14a^6}{81y^7} +$ &c. For $P = y^3$, $Q = \frac{-aa}{yy}$, $m = -1$, $n = 3$, $A = P^{\frac{m}{n}} = y^{3 \times -\frac{1}{3}} = y^{-1} = \frac{1}{y}$, $B = \frac{m}{n}AQ = -\frac{1}{3} \times \frac{1}{y} \times -\frac{aa}{yy} = \frac{aa}{3y^3}$, &c.

3. Simple powers may be found in the same way. Thus, if $\overline{d+e}^5$, or $\overline{d+e}^{\frac{5}{1}}$ were required. Then by the rule $P = d$, $Q = \frac{e}{d}$, $m = 5$, and $n = 1$. Hence, $A = P^{\frac{m}{n}} = d^5$, $B = \frac{m}{n}AQ = 5d^4e$, &c. $C = 10d^3e^2$, $D = 10d^2e^3$, $E = 5de^4$, $F = e^5$; and lastly, $G = \frac{m-5n}{6n}FQ = 0$.

Here the series terminates, and therefore $\overline{d+e}^5 = d^5 + 5d^4e + 10d^3e^2 + 10d^2e^3 + 5de^4 + e^5$.

4. Di-

4. Division may be performed by the same rule. Thus, if it were required to divide 1 by $d+e$. Then $\frac{1}{d+e} = \overline{d+e}^{\,-1} = \overline{d+e}^{\,-\frac{1}{1}}$. Hence by the rule, $P = d$, $Q = \frac{e}{d}$, $m = -1$, $n = 1$, $A = P^{\frac{m}{n}} = d^{-\frac{1}{1}} = d^{-1} = \frac{1}{d}$, $B = \frac{m}{n} AQ = -1 \times \frac{1}{d} \times \frac{e}{d} = -\frac{e}{d^2}$, and $C = \frac{ee}{d^3}$, $D = -\frac{e^3}{d^4}$, &c. That is, $\frac{1}{d+e} = \frac{1}{d} - \frac{e}{d^2} + \frac{e^2}{d^3} - \frac{e^3}{d^4} +$ &c.

See *Newt. Epist. ad Oldenburgh.* Tom. 3. Oper. Wallis. *Analys. per quant. Series*, &c. Lond. 1711. p. 23. seq.

The method of extracting the *roots* of numbers, mentioned in the Cyclopædia under the head EXTRACTION, is the same as that given long ago by Vieta, and is to be met with in almost all books of arithmetic and algebra. Monf. de Lagni and Dr. Halley have given us much more expeditious methods. Dr. Halley's rules for the square and cube are inserted in the Cyclopædia, under APPROXIMATION; only one of the formulæ for the cube is erroneously printed. We shall here insert the doctor's rules which extend to the seventh power, and may easily be continued at pleasure, the law of the continuation being obvious.

$$\sqrt{aa \pm b} = \sqrt{aa \pm b}, \text{ or } a \pm \frac{ab}{2aa \pm \frac{1}{2}b}.$$

$$\sqrt[3]{a^3 \pm b} = \frac{1}{2}a + \sqrt{\frac{1}{4}aa \pm \frac{b}{3a}}, \text{ or, } a \pm \frac{ab}{3a^3 \pm b}$$

$$\sqrt[4]{a^4 \pm b} = \frac{2}{3}a + \sqrt{\frac{1}{9}aa \pm \frac{b}{6aa}}, \text{ or, } a \pm \frac{ab}{4a^4 \pm \frac{3}{2}b}$$

$$\sqrt[5]{a^5 \pm b} = \frac{3}{4}a + \sqrt{\frac{1}{16}aa \pm \frac{b}{10a^3}}, \text{ or, } \pm \frac{ab}{5a^5 \pm 2b}$$

$$\sqrt[6]{a^6 \pm b} = \frac{4}{5}a + \sqrt{\frac{1}{25}aa \pm \frac{b}{15a^4}}, \text{ or, } a \pm \frac{ab}{6a^6 \pm \frac{5}{2}b}$$

$$\sqrt[7]{a^7 \pm b} = \frac{5}{6}a + \sqrt{\frac{1}{36}aa \pm \frac{b}{21a^5}}, \text{ or } a \pm \frac{ab}{7a^7 \pm 3b}$$

For the application of these formulæ or rules, observe, that a denotes the nearest *root* to that of the proposed number, whether greater or less than the true; and that b is the difference between this *root*, involved to the proper power, and the proposed number. Thus, if it were proposed, to extract the cube *root* of 231, the nearest cube to it is 216, the *root* of which is $6 = a$, and the difference between 231 and 16 is $15 = b$. The *root* required will therefore be $= \frac{1}{2}a + \sqrt{\frac{1}{4}aa + \frac{b}{3a}} = 3 + \sqrt{9 + \frac{5}{6}} = 3 + \sqrt{9.8333} = 6.1358$. But this is only a first approximation. For a second suppose $6.1358 = a$; then its cube will be $= 231.000853894712$, which is greater than the truth, and the difference $0.000853894712 = b$. Therefore the *root* $= \frac{1}{2}a + \sqrt{\frac{1}{4}aa - \frac{b}{3a}} = 3.0679 + \sqrt{9.41201041 - \frac{0.000853894712}{18.4074}} = 6.13579243966195897$ true to the eighteenth figure, which Dr. Halley assures us he computed within an hour.

By this example the method of working may be sufficiently clear, and the use of the double sign $\pm$ is obvious. When a is less than the truth, then $a^3 + b$ represents the given number; but when a is greater than the truth, the proposed number will be represented by $a^3 - b$. In the first case, the *root* is $\frac{1}{2}a + \sqrt{\frac{1}{4}aa \pm \frac{b}{3a}}$, or $a + \frac{ab}{3a^3 \pm b}$, and in the second case it is $\frac{1}{2}a + \sqrt{\frac{1}{4}a^2 \quad \frac{b}{3a}}$, or $a - \frac{ab}{3a^3 - b}$.

Dr. Halley justly observes, that the irrational formulæ, $\frac{1}{2}a + \sqrt{\frac{1}{4}aa \pm \frac{b}{3a}}$, is preferable to the rational, $a \pm \frac{b}{3a^3 \pm b}$; because the extraction of the square *root* is much easier than a division by so great a divisor, as $3a^3 \pm b$.

These rules are at least triple the figures of the *root* at every new operation. Thus, in the foregoing example, by the first operation, we had five figures, *viz.* 6.1358 for the *root*; and at the second, we had the *root* true to eighteen places.

Monf. de Lagni published a rule for the sursolid *root*, or fifth power, which quintuplicates the figures of the *roots*, at least. The rule is this,

$$\sqrt[5]{a^5 \pm b} \quad \sqrt{\frac{1}{2}a + \sqrt{\sqrt{\frac{1}{4}a^4 \pm \frac{b}{5a}} - \frac{1}{4}aa}}$$

See Phil. Trans. N° 210, or Lowthorp's Abridgment, Vol. 1. c. 1. Sect. xx. p. 81. Mac Laurin's Algebra, p. 242. Simson's Algebra, p. 155. Where various general theorems for approximation to the *roots* of pure powers are given. See also EQUATION.

For common use, these extractions may be most commodiously performed by logarithms: dividing the logarithm of the power by the index of the required *root*, that is two for the square, three for the cube, &c. the quotient is the logarithm of the *root*; which may therefore be found by the tables.

In some books we have tables of square and cube numbers, by which the nearest square or cube to any proposed number within the limits of the table, may be found by inspexion. *Prestet* has given a table of this kind in his *Elemens des Mathematiques*.

For the *roots* of adfected equations. See EQUATION.

Seminal ROOT. See the article SEMINAL.

Cube ROOT, in geometry. Observe, that the *cube root* of any quantity A^3 may be A, or $\frac{-1+\sqrt{-3}}{2} \times A$, or $\frac{-1-\sqrt{-3}}{2} \times A$.

This follows from what was shewn under the head UNITY, that the *cube roots* of unity or 1 are 1, $\frac{-1+\sqrt{-3}}{2}$, $\frac{-1-\sqrt{-3}}{2}$. Hence the *cube roots* of A^3 or of $1 \times A^3$ will be as above mentioned. *Mac Laurin*'s Algebr. p. 226. where he shews the use of such expressions.

In general, every power has as many *roots*, real and imaginary, as there are units in the exponent of the power. *Mac Laurin* Ibid. p. 128.

Impossible ROOT is not only the square *root* of a negative quantity, but any other *root* denominated by any even number. Thus $\sqrt[4]{-1}$, $\sqrt[6]{-1}$, $\sqrt[8]{-1}$, or in general $\sqrt[2m]{-1}$ or $\sqrt[2m]{-x}$ are all impossible roots, or quantities.

Some call them *imaginary roots* or quantities.

ROPALON, in botany, a name given by some authors to the *nymphæa*, or *water lilly*, and also to the *faba ægyptia* of the river Nile.

ROPE (*Cycl.*)—*Standing* ROPES, in a ship, the shrowds and stays are so called, because they are not removed, unless to be eased or set taught.

ROQUET, in zoology, the name of a species of American lizard, of small size, and of a reddish brown colour, variegated with black and yellow spots. Its fore legs are remarkably long for a creature of this kind; its eyes are particularly vivid and sparkling, and its head is carried continually erect; and the creature is almost eternally in motion, hopping about like a bird, and it usually carries its tail bent into a semi-circle over the back. It is far from being shy or timorous, and is delighted at the sight of men; when tired with play or with running, it will open its mouth and pant, and loll out its tongue as the dogs do. *Rochefort*, Hist. Antill.

ROS (*Cycl.*—ROS *mayalis*, *maydew*, the *dews* that fall in the beginning of summer, particularly in this month, have great virtues attributed to them by many authors, when newly gathered and clean filtered. It is not of a watery appearance, or colourless, but is yellowish, and much resembles the urine of a healthful person. The common methods of putrifying water also have no effect on *dew*. Several quantities of it have been placed in digestion with different degrees of heat, from that of dung to that of a sand surface, but no putrefaction brought on it, though continued two months together; the heat, in whatever degree, serving to purify it, not to hurt it. The summer sun, for all the hot months together, has no more effect on it. It only sends out a green vegetable matter of the conferva kind which floats on the surface, and adheres to the sides of the vessel, and the whole quantity of the liquor remains as pure as before. Phil. Trans. N° 3.

Though these common methods of putrefaction do not take place in this fluid, a much more simple process will. If a quantity of it be put into an open wooden vessel, and set in a cool shady place, with a canvas stretched over it to keep out dust and insects, it will in three or four weeks putrefy and stink, and deposite a large quantity of a black and thick mud. The manner of the formation of this sediment is this: a small quantity of a foul matter first separates itself from the liquor, and floats at the top in form of a skin or film; this soon after precipitates itself to the bottom, and another succeeds in its place at the top, which is soon after precipitated in the same manner. Thus the mud is a congeries of these films one on another. If a quantity of *dew* be put into a long and narrow glass vessel, these films, instead of sinking, as soon as formed, will combine one with another at the top, and form a thick scum, which may be taken off with a spoon, and is very different from the black mud, separated to the bottom in the former experiment, being

being a white and thick flime: if a quantity of this be put into a drinking glafs, or other fuch veffel, and the water drained from it, it will fomewhat fhrink in twelve hours ftanding, and will become fo folid as to take the form of the glafs, and may be fhook out; it then refembles a lump of boiled white ftarch, but is fomewhat more tranfparent.

We have, in the Philofophical Tranfactions, a very remarkable account of a vegetable production from this jelly. A perfon having put a quantity of it into a double veffel, in order to putrify it, obferved, that after fome days, the moifture was in great part evaporated, through a fault in the luting of the junctures, and that a large mufhroom was growing up out of the almoft dry refiduum. It was, he fays, of a fpungy and watery nature, and of the fame nature with fome which he had feen growing out of rotten wood. The warmth employed in this digeftion was that of a *balneum mariæ*. The probable account of this is, that the feeds of this mufhroom, which are very light, and eafily wafted about every where by the winds, had fallen into the jelly, in the time of its being expofed; and finding it a proper nidus, had, by means of the additional warmth, which is alfo greatly beneficial to all the mufhroom clafs, been fet a growing, and arrived at their perfection in the form of the parent plant they fell from. There are in the fame paper other odd accounts of productions of the animal kingdom, in the fame *dew*, which might puzzle any one not verfed in experiments of this kind with other fluids. In one of the veffels of this *dew* he found millepides, differing from the common kind in fome particulars. Thefe were the common water millepides; and in another he found a quantity of green matter, probably a conferva, with numerous eulæ of infects inhabiting it; for in a few days there were produced from this a vaft number of flies. Another parcel of the *dew*, fet in an open glafs, was found after fome days filled with the eulæ of the common gnat, and the flies were hatched from thefe. Phil. Tranf. N° 3.

It is eafy for a bad philofopher to infer from thefe accounts the equivocal generation of thefe creatures in the water; but the infight we have had into the wonders of nature in the infect world are fuch, that at prefent we know their generation to be in many fpecies, particularly in the gnat and fly kinds, from the eggs of their parents depofited in water, or any watery fluids, and that common ditch water will at any time do what the *dew* does in this experiment.

ROS *folis*, *fundew*, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the rofaceous kind, compofed of feveral leaves, arranged in a circular form. The cup is tubular, and the piftil which arifes from it is at length converted into an oval pointed fruit, which opening at the extremity, difcovers a number of oblong, or roundifh feeds. To thefe marks, it is to be added, that the leaves are covered with long hairs, from which there feem to be feparated large drops of water.

The fpecies of *fundew* enumerated by Mr. Tournefort are thefe. 1. The common round leaved *fundew*. 2. The common long leaved *fundew*. 3. The perennial round leaved *fundew*. 4. The perennial long leaved *fundew*. 5. The largeft, long leaved *fundew*; and 6. The Portugal *fundew*, with leaves like thofe of the fmaller afphodel. *Tourn.* Inft. p. 244.

ROSA, the rofe. See the article ROSE.

ROSA *crucis*, in church hiftory. See ROSYCRUCIANS, *Cycl.*

ROSA *fatuina*, in botany, a name given by fome authors to the piony.

ROSA *junonis*, in botany, a name given by fome authors to the lilly.

ROSACEOUS *flower*, *rofaceus flos*, in botany, a term ufed to exprefs fuch flowers, as are compofed of feveral petals or leaves, difpofed in a fort of circular form, like thofe of the rofe: fuch are the flowers of the piony, crowfoot, cinquefoil, *&c.* In this fort of flowers the difpofition only of the leaves is regarded, their number being of no confequence. It is very feldom that the number is two or four, except in the circæa and onagra. The moft frequent number of leaves in thefe flowers is five, and fuch as have four differ from the cruciform flowers, not only in their difpofition, but in this, that the number is in the fame fpecies indeterminately four, five, or fix, as is the cafe in the clematitis, the capers, and the fpecies of rue, whereas in the cruciform ones it is ever conftant. See Tab. 1. of Botany, Clafs 1. *Tourn.* Inft. p. 234.

ROSACLORUM, or according to fome authors *rofi-chiero*, a fine red ufed to enamel on gold with. It is prepared in this manner: take ten pound of cryftal glafs, put it into a pot, and when it is well melted, add to it, at twice, a pound of the beft red lead, ftir the mafs well together, and afterwards caft it into water. Repeat this procefs three times, then when the matter is again in fufion, mix with it five ounces of calcined brafs, and the fame quantity of the deepeft cinnabar; ftir the whole well together, and let it fettle three hours; then add of glafs of tin three ounces, mix the whole, and it will be of a fine rofe colour. *Merret's* Notes on Neri, p. 350.

ROSALIA, a name ufed by authors for the meafles, or a difeafe very like the meafles, confifting in a number of afperities and protuberances of the fkin, which foon die away.

ROSARBA, in botany, the name of an imaginary plant, which has given great trouble to the commentators on the works of the antients.

The Arabian writers, Avifenna, Serapion, and others, have mentioned two kinds of carob or ceration; the one efculent, and endued with the virtue of a gentle purgative, the other an aftringent.

This laft they have diftinguifhed from the other by the name of the nabathæan pod or aljembut. They fay, in their defcriptions, that the aljembut is like the *rofarba*, fo run the old tranflations, but the true meaning of the original is *rofa vineæ*. This was a name given to the common wild acacia tree, and the tree which produced the nabathæan pod, might be very well likened to this; it being, in reality, only a fpecies of the acacia, and the fuccus acaciæ, or infpiffated acacia juice of the fhops; being, according to Ifidore, made oftentimes from the unripe fruit of this very fpecies.

ROSARIA, among the Romans, a kind of perfumes, fo called, either from their being chiefly made of rofes, or becaufe they had a moft exquifite odour.

ROSARY (*Cycl.*) is a word frequently met with in the antient hiftories of Ireland, and ufed to exprefs a peculiar fort of bafe money coined abroad, in the form of the penny, current in that kingdom; but of fo much bafer an alloy, that it was not worth quite half the real value of the penny. This and many other fuch coins were decried, and it was made death to import any of them by Edward the firft in 1300.

ROSBOTH, a word ufed by fome authors to exprefs a foft excrefcence from any part.

ROSCOLÆ, a name given by fome medical writers to the meafles.

ROSE, ROSA, in botany, the name of a genus of trees, the characters of which are thefe. The flower is compofed of feveral petals arranged in a circular form. The cup is compofed of feveral leaves, and finally becomes a roundifh or oblong flefhy fruit, which is unicapfular, and contains a number of angular hairy feeds.

The fpecies of *rofe* enumerated by Mr. Tournefort are thefe. 1. The fingle red *rofe*. 2. The double red *rofe*. 3. The double reddifh black *rofe*. 4. The red *rofe* which does not open. 5. The fingle pale red *rofe*. 6. The double pale red *rofe*. 7. The deep or blackifh red *rofe*. 8. The purple *rofe*. 9. The fingle purple *rofe*. 10. The changeable coloured *rofe*. 11. The Englifh changeable *rofe*. 12. The red and white variegated *rofe*. 13. The Ciphian *rofe*, or fmall pimpernel leaved Scotch *rofe*, with elegantly variegated flowers. 14. The greateft double *rofe*. 15. The middle fized double *rofe*. 16. The great fingle white *rofe*. 17. The great double white *rofe*. 18. The fmall white *rofe*. 19. The large mufk *rofe*. 20. The fingle flowered mufk *rofe*. 21. The double flowered mufk *rofe*. 22. The evergreen mufk *rofe*. 23. The large flowered *rofe* without prickles. 24. The fmall flowered *rofe* without prickles. 25. The curled leaved *rofe* with bright red flowers. 26. The common wild *rofe* with a pale fweet fcented flower. 27. The wild *rofe* with a large deep red flower. 28. The double flowered dog *rofe* or wild briar. 29. The *eglantine*, or *fweet briar*, with double flowers. 30. The common fingle flowered *fweet briar*. 31. The wild *rofe* with red very fweet fcented flowers. 32. The wild *rofe*, with a white very fweet flower. 33. The fingle cinnamon *rofe*. 34. The double flowered cinnamon *rofe*. 35. The fmall red *rofe*, commonly called the May *rofe*. 36. The fingle yellow *rofe*. 37. The double yellow *rofe*. 38. The very thorny field *rofe* with a white fweet fcented flower. 39. The dwarf very thorny *rofe* with red flowers. 40. The dwarf alpine *rofe*, with fmall roundifh pimpernel leaves, and very little flowers, of a livid red. 41. The wild dwarf red *rofe*. 42. The great wild apple *rofe*. 43. The white field *rofe*. 44. The creeping white field *rofe*. 45. The fmalleft *rofe*. 46. The two flowered field *rofe* without prickles. 47. The pale red mouth *rofe*. 48. The white mouth *rofe*. 49. The double pale red mouth *rofe*. 50. The fingle purple mouth *rofe*. 51. The crimfon *rofe*. 52. The Frankfort *rofe* with a thick cup, which does not open its flowers; and 53. The wild *rofe* or briar with large hairy fruit. *Tourn.* Inft. p. 637.

We have a vaft variety of thefe beautiful flowers preferved in our gardens; fome few of which are natives of our own country, but the far greater number are of foreign origin. They are all propagated either by fuckers, by layers, or by binding them on the other forts of *rofes*; the laft method is but feldom practifed, but is neceffary for the finer forts, which do not naturally fhoot vigoroufly, and which produce few or no fuckers. The beft fort of *rofe* for ftocks is the Frankfort kind; the feafon for doing it is in June, and there muft be great care afterwards, that the ftock produce no fuckers at the bottom, for thefe would foon ftarve the bud. *Miller's* Gardner's Dict.

When *rofes* are to be propagated from fuckers, they are to be taken off annually, and planted into nurfery beds, or into the places where they are to remain. They always take

take root well the firſt year, but if ſuffered to remain on the ſtock longer, they grow woody, and often fail.

But the beſt method of obtaining vigorous plants, is, by laying down the ſhoots; this is to be done in autumn, and by the autumn following they will have taken root ſo well, that they may be taken off from the old plant, and removed to the places where they are to remain. Theſe may be tranſplanted any time from October to April, but the earlier the better.

Roſes, in general, delight in a rich moiſt ſoil, and an open ſituation, in which they will produce great quantity of flowers, and thoſe much more beautiful than when they are on a dry ſoil and ſhady ſituation.

All the pruning they require is to have their dead wood cut, and their ſuckers taken away every autumn; and if there are any very luxuriant branches they may be ſhortened, and the doing this will ſupply the other parts of the tree with freſh wood. *Miller*'s Gardners Dict.

Eſſence of ROSES. There is ſcarce a more valuable perfume in the world than the eſſence of damaſk *roſes*, and ſcarce any thing is obtained from its ſubject with more difficulty and in leſs quantity. All eſſences or eſſential oils are, while in the plant, contained in certain veſicles, lodged in different parts, and of different ſtructure; theſe veſicles are in the *roſe* particularly ſmall and tender, and are placed very ſuperficially; the conſequence of this is, that there is originally but a very little of this eſſence in the flower, and this is the very ſubject that will be diſſipated and loſt when the flowers are gathered and thrown in a heap together, as they are ſucculent, and very quickly heat in lying together. To avoid all diſſipation and waſte of this choice eſſence, the *roſes* ſhould be thrown into the ſtill as ſoon as gathered, and diſtilled with very little water, and that in a balneum mariæ; then the fire is to be continued ſo long as the flowers float ſeparate about in the water; but as ſoon as ever they form themſelves into a cake, and ſtick to the bottom, the diſtillation ſhould be finiſhed, as they then yield no more eſſence. With all theſe precautions, however, it is with great difficultly we can procure any eſſence of *roſes*. What we obtain by this diſtillation being chiefly a very odoriferous and fragrant water. In the warmer countries the ſame caution affords a larger quantity of oil, which may be ſeparated and preſerved under the name of the eſſence. In Italy they make ſome quantity of it, but there it is very dear; a vaſt quantity of the flowers yielding only a very little eſſence, and that being thick and troubleſome in the procuring, as it every where ſticks to the veſſels.

It is to be obſerved, that the ſeaſon of the year, as to wet or dry, makes a very great difference in the eſſential oils of all plants; they are always much finer in dry and hot ſeaſons than in cold and moiſt: we find our *roſe* water in England much finer, and more fragrant, though diſtilled in the ſame proportion in hot and dry ſummers than in colder and rainy ones; and Mr. Geoffroy gives an account that he ſucceeded, one very hot and dry year, in the making eſſence of *roſes* in France, in the following manner.

As the *roſes* were brought to him freſh gathered, he turned them immediately into the ſtill; and drawing over the water into a glaſs matraſs, when it had ſtood by ſome time, and was perfectly cold, he diſcovered ſome of the eſſence fixed to the ſides of the matraſs, and the ſurface of the water covered with a thin reticular pellicle. All the contents of the matraſs were put to filter through a paper, ſupported by a fine linnen cloth; and the filtrated water was added to new *roſes* for many ſucceeding diſtillations, the produce of which was all filtered through the ſame paper. After a long courſe of diſtillations, with freſh flowers every time, but ſtill with the ſame veſſels and the ſame water, there was found in the paper of the filtre a quantity of thick eſſence; this being carefully waſhed out of the paper with a ſmall quantity of the moſt fragrant of the water, and afterwards ſeparated pure from its ſurface was very white, and extremely fragrant, and as thick as fine butter. This is not the only eſſential oil which naturally concretes into this firm ſtate; oil of anniſeed, though fluid, when diſtilled, always concretes in the ſame manner on the firſt approach of cold; and another oil of this kind is that of the laurel, which is uſed in ſome places, though very improperly, to give the ſcent and taſte of bitter almonds, or apricot kernels, to foods of different kinds.

Monſieur Homberg has taught us how to gain a larger quantity of the eſſential *oil of roſes* than is uſual in diſtillation, by the previous addition of mineral acids, as the ſpirit of ſalt, vitriol, &c. thereto; which increaſe the fermentation, and joining with the *oil* render it more liquid, and eaſier to be raiſed by heat. He adviſed a perfumer, who before ſcarce obtained an ounce of *oil* from an hundred weight of *roſes*, to ſteep his flowers for fifteen days in water made ſharp with ſpirit of vitriol, by which means the perfumer, upon diſtillation, found his quantity of *oil* increaſed almoſt a third.

The perfumers keep the ſtructure of the veſſel they employ in this diſtillation in great ſecret. Mr. Homberg tells us, it is a large convenient ſtill, that opens in a tube at the top to receive the water which muſt often be poured upon the *roſes* to bring over the *oil* with it; this it does but very ſlowly, and ſo requires that its quantity be large; the ſtill alſo opens below, that the flowers, when they will yield no more *oil*, may be eaſily taken out; but the principal contrivance is the figure of the veſſel which receives the *oil*; this is made like an ordinary matraſs, from the lower part of the belly whereof comes a tube, as from an old faſhioned cruet, and riſing to the bottom of the neck of the receiver, it bends outwards; ſo that though the veſſel uſually contains but two or three French pints, it conveniently receives and lets paſs many hundred pints of the *roſe* water, without any neceſſity of being changed; for a change would loſe the ſmall quantity of the *oil* obtained. The water diſtilled runs through a pipe into a ſecond receiver: the *oil* being lighter than the water, floats upon its ſurface, and adheres to the neck of the veſſel as high as the aperture of the little pipe, while the water runs from the bottom of the firſt receiver into the ſecond. See Mem. de l'Acad. des Sciences, 1700.

Mr. Homberg obſerves that this ſtill may be uſeful to draw off any kind of precious eſſential *oils*.

ROSE *fly*, in natural hiſtory, the name given by authors to a peculiar ſpecies of *fly* found very frequently on *roſe* buſhes, and produced out of a baſtard caterpillar, which feeds on the leaves of that tree.

The male of this *fly* has a long body, the female a ſhort and thick one; ſhe depoſits her eggs in ſmall holes, which ſhe makes in the bark of the young branches, and for this purpoſe is furniſhed with a very remarkable inſtrument placed at the hinder part of the body, which is a kind of ſaw. This is a four winged *fly*, and is ſo common on *roſe* buſhes, that it is ſcarce poſſible to miſs it in any of the ſummer months; and the parts of the branches where it has depoſited its eggs, are ſo vitiated by it, that they alſo are eaſily known. They are uſually ſwelled to a greater bigneſs, than either the part above or below them, and are uſually ſomewhat bent; they are often black on the underſide, and among this blackneſs the holes made for the eggs, and often the eggs in them may be ſeen. The head and breaſt of this *fly* are black. Its wings alſo are edged with black, its body is yellow, and its legs yellow, with a few black ſpots.

If theſe *flies* be obſerved in a ſummer morning, as they are crawling upon the branches of the *roſe* tree, they will ſoon be found at work for the depoſiting of their eggs. Theſe creatures give us a very good opportunity of obſerving the manner in which they perform this, as they are of a very ſluggiſh diſpoſition, and will ſtand ſtill even to be taken between the fingers; ſo that when one of them is in a proper ſituation, it may be examined, by bringing the eye near it, and by uſing the common magnifying glaſſes, without quitting its place or its work; and if there be leaves of the tree, or ſmall branches of it in the way, they may be removed without diſturbing the creature. *Reaumur*'s Hiſt. Inſ. Vol. 9. p. 145.

As ſoon as the *fly* has found a proper place for her eggs, ſhe directs the hinder part of her body downwards, and opening a pair of ſcaly ſubſtances placed near her tail, ſhe thruſts out from between them an inſtrument exactly repreſenting two common ſaws, with ſharp teeth and ſmooth backs; when ſhe has ſo placed theſe, that their points touch the bark, ſhe preſſes down her body in order to force the points to enter, and afterwards continues this preſſure till the whole length of both ſaws is immerſed in the wood. If the whole be nearly examined, however, it will be found that a ſimple preſſure is not all the means employed to force them in; but that as ſoon as ever the points are entered the bark, the two ſaws begin to work by means of tendons and muſcles made for that purpoſe, and are moved about exactly as the common ſaw in the hand of a carpenter; only that as there are two of them, they always move the contrary way, one being forced in while the other is drawn out; by this means they become a ſupport to one another.

As theſe inſtruments are extremely ſmall, they would not naturally cut an opening large enough for the receiving and covering the egg which is to be depoſited there. The creature therefore uſes great art and addreſs in the working with them. She opens the branch, not by making a bare puncture, but in the ſame manner in which a ſurgeon opens a vein, by plunging the point of his lancet perpendicularly in, and then raiſing it out obliquely; and, in order to enlarge the width of the wound, ſhe makes the teeth of each of the ſaws work forcibly againſt the ſides of it at every return. When the aperture is thus made of a proper ſize, the creature immediately draws out the ſaw, and preſſing her body down upon the bark, depoſits an egg in the hole; immediately after which, ſhe covers the orifice with a viſcous fluid, which bubbles up in the manner of ſoap ſuds, and ſerves at once to preſerve the egg, and to prevent the wounded fibres of the tree from decaying too ſoon. Ib. p. 150.

When the laying of one egg is thus finiſhed, the creature moves a little way forward or backward on the branch, and then begins the like operation for another egg, and goes on in this manner till ſhe has laid her whole ſtore. If the branch be all the way proper to receive them, ſhe lays them

them in a train, twenty or more, at ſmall diſtances, in a ſtrait line before one another; but if ſhe finds the branch become leſs proper for her purpoſe after ſhe has laid three or four, ſhe leaves it and ſeeks out another, where ſhe finiſhes what ſhe had there begun. There is not any apparent difference in the ſeveral young branches of the ſame *roſe* tree, that can ſhew us why one is, and another is not proper for this purpoſe; but the creature herſelf is very curious in her choice, and uſually examines a great number before ſhe fixes upon a proper one. The operation might ſeem very difficult to ſo ſmall an animal; but though the creature be of a very ſluggiſh diſpoſition, in all reſpects, it ſeems to find no trouble in this, and will uſually finiſh the laying ſix eggs in this manner in half an hour. The apertures are ſo ſmall, that there are uſually about fifteen of them in the ſpace of an inch, and yet there is always a ſmall ſpace between each, and thoſe above and below it. On ſtripping the bark from one of theſe branches, the wounds are ſeen to enter into the wood, and reſemble ſo many openings of a vein, by a ſurgeon in blood letting. In each of theſe there is depoſited one egg, which is conſiderably large, of a yellow colour, and pointed at one end. If the branch of a *roſe* tree, in which the eggs of this inſect are thus depoſited, be examined from time to time afterwards, the part where they are placed will be found to change colour, the bark will turn brown and then black, and the wounded parts will elevate themſelves above the reſt of the ſurface, and reſemble a ſtring of beads, or a long chain of olives. This elevation of the wounded parts is not to be attributed to the growth of them; but they are, on the contrary, ſo far deſtroyed, as to be rendered incapable of increaſe that way. This ſwelling is owing to another very ſingular cauſe, which perhaps nature does not give us another inſtance of in the whole animal world. The egg daily increaſes in ſize after it is laid, and this is very evidently ſeen on opening the ſeveral lodgments, formed at different times; thoſe which have been made two or three days, always containing eggs more than twice as large as thoſe made within a few hours. It is to be obſerved, in favour of this ſtrange occurrence, that the egg of this creature is not covered with a hard ſhell in the manner of a bird's egg; but only with a thin, and eaſily diſtenſible membrane; but then all other eggs of inſects are in the ſame manner covered with a diſtenſible membrane, not a hard ſhell, and yet none of them are ever known to increaſe in ſize after their being laid. The egg, in thus increaſing in ſize, raiſes up the wood and the bark which cover it; and in conſequence of this, the train of eggs make a ſtring of regular elevations of the part, as the egg increaſes, and the tumor grows larger; the aperture at the ſurface grows alſo wider in proportion, ſo that the worm, when hatched out of it, finds no difficulty in getting out, but immediately crawls to the leaves and begins eating.

There is, beſide this ſpecies, another *fly* of the ſame genus, produced from a baſtard caterpillar of the *roſe* tree, and of the ſame ſhape and ſtructure of parts with this, but differing in colour: the head and breaſt of this *fly* are of a deep violet colour, the body is yellow, and the legs and wings are of a ſomewhat paler violet tinge. This creature alſo depoſites its eggs in holes, made in the branches of the *roſe* tree, by means of a double ſaw placed at the hinder part of the body; but, as the former ſpecies lays them in a ſingle ſtrait line, this diſpoſes them in a very beautiful and very regular manner in two rows. Two eggs are firſt laid by the creature, at ſome ſmall diſtance, ſideways, one from another, but at the ſame height of the branch. The bottoms of theſe meet almoſt one with the other; but their tops are expanded a little, ſo that they make an acute angle, or expreſs the ſhape of the letter V; behind theſe there are placed two others, making a ſomewhat wider angle, and ſo behind theſe two others. Thus the creature frequently depoſits ten, twelve, or fourteen pair of eggs, which are all placed at ſome ſmall diſtance from one another, and are ſeparated into two diſtinct rows by an intermediate line. Theſe are not ſo well defended from injuries as the eggs of the former ſpecies, and are entirely buried in the wood; and lodged in ſuch large holes, that they appear naked even when firſt laid. Mr. Valliſnieri, who has elegantly deſcribed this inſect, obſerves, that as the ſaws of the former ſpecies are toothed only on one ſide, having a flat back in the manner of our common ſaws, thoſe of this ſpecies are toothed both ways: he obſerves alſo, that the two pieces which make a caſe for theſe ſaws, and which are opened to give them paſſage when they are to be uſed, are each of them hollow, and are of the greateſt uſe to the creature; the one ſerving as the paſſage for the eggs, the other for that of the glutinous liquor with which the creature covers the wound in the wood, after depoſiting her egg in it. But Mr. Reaumur, in comparing the ſize of the egg, when new laid, with the aperture, which this author ſuppoſes it to be depoſited through, is of opinion that it is much too large to have gone through ſuch a paſſage; he alſo obſerves, that the eggs may always be forced out of the body by preſſing it between the fingers; but that, in this caſe, they are always ſeen iſſuing out at the anus.

The *roſe* tree ſeems the peculiar favourite of theſe ſorts o flies, for beſide the two ſpecies already deſcribed, there is another very ſmall one which is found on this tree in great abundance in the months of April and May. This is every way ſhaped like the large kinds, but it is all over black except ſome white ſpots on the legs; the ſaw of this ſmall inſect is not of a ſufficient ſtrength to penetrate the branches of this ſhrub, it therefore always is ſeen upon the leaves, and depoſits its little eggs in a row of holes made in the middle rib of a leaf. It is to be obſerved that all the falſe or baſtard caterpillars produce theſe ſerrated flies; yet it is very ſingular that they do not all make the ſame apparent uſe of their ſaws that theſe do. The fly produced by the falſe caterpillar of the gooſeberry, always depoſits its eggs in ſingle rows along the middle ribs of the leaves; but the eggs are not let into them by holes made for that purpoſe, but are merely laid along upon the ſurface. It may be however, that the creature makes a wound where every egg is to be depoſited, which though not large enough to receive it, may yet ſuffice to afford a neceſſary moiſture to it. Mr. Reaumur was at the pains to keep ſome of the falſe caterpillars produced from the eggs of this fly the whole ſeaſon, and obſerve them through all their changes. When they had eaten ſufficiently in the caterpillar ſtate, they crept into the earth which he had put into the bottom of his boxes, and then changed into chryſaliſes in a double covering of a ſilky matter of their own ſpinning; they remained all the winter in this ſtate, and in the ſucceeding ſpring came forth out of the earth in form of flies. This author obſerves, that on putting a male and female together into another box, in which there were ſome branches of gooſeberry buſhes, the female immediately ſearched out the proper places for depoſiting her eggs, and laid ſeveral before his face in ſingle rows on the moſt prominent part of the ribs of the leaves: the creature ſeemed to give herſelf all the motions that the other ſpecies do in piercing the branches of the *roſe* tree, before the depoſiting of every egg; but that on examining the places afterwards, he never could find any mark of a wound in them, the eggs all lay upon the ſurface, but they were ſo firmly fixed on the place, that there was no removing them without breaking them, and a piece of the ſkin was always left behind, which ſtuck faſt on the place and covered the hole if there was any. There are alſo ſome other ſpecies of theſe *flies*, which make no apparent uſe of the curious ſaws they have behind: yet they all are poſſeſſed of them. *Reaumur's* Hiſt. Inſ. Vol. 9. p. 160. See the article SERRATE *Flies*.

ROSE *galls*, in natural hiſtory, a name given by authors to certain unnatural productions of the *roſa ſylveſtris*, or dog *roſe*, occaſioned by the bites of inſects: there are two kinds of theſe, the one very common, the other more rare.

The ſcarcer kind is uſually found on the young ſhoots, and on the heps or fruit, and is of a woody ſubſtance; the other is hairy and ſpungy and is found on the old branches. The woody kind uſually appears in the months of June and July, and is always found in cluſters. Theſe are compoſed of ten, twelve, or more *galls* of different ſizes and figures, ſome round, others oblong, ſome of the ſize of an olive, and others not larger than a pea. They are of the common ſubſtance of the white wood or blea of trees, and when ſituated on the fruit they prevent its ripening and make a very ſingular figure. They are of a reddiſh colour and are uſually ſmooth and gloſſy, but ſometimes they are beſet with ſhort and fine prickles.

The hairy *roſe gall* is too common, and too ſingular a figure to have eſcaped the obſervation of perſons in all ages; it has been introduced into medicine in many parts of the world, and is at this time preſcribed in Germany, when reduced to powder, in diarrhœas, dyſenteries and other diſorders of the bowels, and to promote urine and break the ſtone. Theſe *roſe galls*, though they appear at firſt ſight compoſed of tufts of hair, are however in reality made up of ſeveral ſmall *galls* growing from a bud on the branch and forming a cluſter on the part. They are of an oblong figure and reſemble the ſhape of a plum-ſtone. Each of them is the habitation of a ſingle worm, each having one cell in the center. This is perfectly ſmooth and even on the inſide, but from the outer ſurface of each of theſe ſeparate *galls* there go off a vaſt number of filaments which uniting and intermingling with one another form one complex maſs, and give the whole cluſter the figure of one *gall* of the bigneſs of an Indian or horſe cheſnut. Theſe filaments are of a reddiſh or greeniſh colour, and are often nearly an inch in length. They are called by ſome hairs, but very improperly, having no true character of a hair, but being of a rough ſurface, flatted, and branched with ſeveral ſhorter filaments growing from their ſides. The tubercles within, from which theſe grow, are of a hardneſs greater than that of moſt ſpecies of wood. Though theſe *galls* are uſually found on the branches of the ſhrub, and ariſing from the buds or eyes of young ſhoots, and are therefore ſuppoſed by authors to be the vitiated matter of a whole

branch

branch with its leaves divided into these filaments, yet they are sometimes found growing to the middle rib of a single leaf, where yet they do not want all their filaments, though there have been no vitiated leaves to form them. *Reaumur's* Hist. Inf. Vol. 6. p. 251.

Though these *galls* and the smooth ones before described are extreamly different in external appearance, yet on a close examination they appear to be more nearly allied than might be suspected. They are doubtless both the work of the same insect, and their principal difference is, that the one is smooth, and the other covered with these filaments. It is to be observed however, that the smooth ones have sometimes a sort of short and soft spines upon them, and these seem the rudiments of these hairs; and there seem to be *galls* found sometimes more, sometimes less hairy, and indeed of all the middle degrees between the two sorts.

The naked *galls* are usually larger and of a more spungy texture than the hairy ones; which is owing to all the matter, which should have formed the filaments, being united and wrought up into the body of the *galls*. There is also another variety of the smooth kind, which might appear an absolutely distinct species. This is a single and large *gall* of a smooth surface and spungy but woody texture. When cut open, it is found to contain several cells, each inhabited by one worm; and when nearly examined is found to be a congeries of as many smaller *galls* as there are cells, which have grown firmly together.

All these *galls* of the *rose* tree afford the same species of worms, and the same species of flies. The proper inhabitants, however, are hardly to be distinguished by the most curious observer from the great variety of species which are found in them, all produced of the eggs of other flies, whose worms are of the carnivorous kind, and are lodged in the *gall*, not to feed on the juices of the tree, but on the flesh of the proper inhabitant. When the parent fly who gives origin to the *galls* has deposited her eggs, and the tumor in consequence begins to be formed, an enemy of this kind pierces the covering, and sends in her offspring to feed on the inhabitant. These are flies of the ichneumon kind, and several species of them are of great beauty. All the flies described by authors as issuing out of this *gall* seem to have been of this kind: the proper inhabitant being a small black fly of no great beauty is disregarded, while the others have been particularly described. Mentzelius has given an elegant account of a species whose back is of a fine blue and its belly purple, and others have figured and described greenish and gold coloured ones, but these are all ichneumons, all bred of devouring enemies which have fed on the proper inhabitants of the *galls*, and lived and transformed themselves in their cells. *Reaumur's* Hist. Inf. Vol. 6. p. 254.

Oil of Roses. See *essence of* Roses, *supra*.

ROSEA, a name given by some authors to the erisipelas or St. Anthony's fire.

ROSLAND, in our old writers, heathy land, or ground full of ling; also watry and moorish land. 1. Inst. 5. *Blount*.

ROSMADIAN, a name used by the alchemists for what they call mercury of the philosophers.

ROSEMARY, *rosmarinus*, in the linnæan system of botany, a distinct genus of plants, the characters of which are, that the cup is a perianthium composed of one leaf, tubulated, and flatted in its upper part; its rim is erect and labiated, the upper lip whole, and the lower indented in three places. The flower is a single petal in form of a tube, and longer than the cup. It is labiated at the extremity; the upper lip is short, erect, divided into two segments, acute, and has bent edges; the lower lip is bent back, and is trifid, the middle segment large and hollow with a narrow base, the lateral ones are narrow, the stamina are two pointed filaments bent toward the upper lip and longer than it, the antheræ are single. The pistil has a quadrifid germen, the style is of the length, figure, and situation of the stamina, and the stigma single and acute. The cup holds in its bottom four oval seeds. *Linnæi* Gen. Pl. p. 6.

The characters of *rosemary*, according to Tournefort, are these. The flower consists of one leaf, and is of the labiated kind; the upper lip is bifid, and turned backwards and upwards, and adorned with crooked stamina; the under one is divided into three segments, the middle one being larger than the rest, and hollowed in the manner of a spoon. The cup is divided into two or three segments, and is furnished with a pistil, which is fixed in manner of a nail to the hinder part of the flower; this is surrounded with four embryos which afterwards become four roundish seeds ripening in the cup of the flower.

The species of *rosemary* enumerated by Mr. Tournefort are these. 1. The common narrow leaved garden *rosemary*. 2. The silver leaved garden *rosemary*. 3. The broad leaved wild *rosemary*. 4. The variegated leaved *rosemary*. 5. The large spiked purple flowered *rosemary*. The several species of *rosemary* when neither in flower or feed may be known by their having hard woody stalks, narrow leaves, and a smell much approaching to that of camphor. *Tourn.* Inst. p. 198.

We have five or six different species or varieties of this shrub in our gardens; they grow wild in the south of France, and in Spain and Italy, on rocks near the sea where they multiply prodigiously. With us they grow the most vigorously on a moist rich soil, but they are much sweeter scented when on a poor soil, and on such they bear the severity of our seasons much better, than where they grow more freely.

They are all propagated by planting slips or cuttings of them, in the spring of the year, on a bed of light fresh earth, and when they are rooted, they are to be removed into the places where they are to remain. The best season for doing this is in August, if they are planted later than this, they seldom live through the winter; therefore such as are not transplanted at this time should be left till the following spring, when March is a very good time for removing them; and if this be done in showery weather they take root almost immediately. The plants are sometimes killed in cold winters in our gardens, but when by accident they have rooted themselves in an old wall, as is often the case, they stand all weathers unhurt, which is owing to their being stunted and their roots dry.

The flowers of *rosemary* are used on many occasions in medicine; they are cephalic, good in all nervous and hysteric cases, and are ingredients in many compositions of the shops; they are esteemed of great service in apoplexies, palsies, vertigoes and epilepsies. They strengthen the sight, are good against a stinking breath; they are also prescribed in obstructions of the liver and spleen: the conserve of the flowers is an excellent thing to bring other medicines in these intentions into form, when they are intended to be given in boluses and electuaries.

The hungary water so long famous in England and elsewhere, is made of the flowers of *rosemary* distilled with rectified spirit of wine.

ROSMARUS, in zoology, the name of an animal called also by some the sea horse, and more usually known by the name *morse*. See Morse.

ROSOMACHA, in zoology, a name given to a species of hiæna. They are, says Olaus, taken by hunters chiefly on account of their skins, which are much esteemed by people of fortune for robes, as being variegated with very bright colours resembling flowers. *Hoffm.* lex univ. in voc. See the article Hiæna.

ROSPUS, a name used by some authors for the strange fish called the *rana piscatrix*, or frog fish. *Willughby's* Hist. Pisc. p. 86. See Rana.

ROSSE, in ichthyology, the name given by Bellonius to that kind of the cyprinus of Artedi which we call the roach. See the article Cyprinus.

ROST, in metallurgy, a term used by the miners at Chemnitz to express the ore of gold after it has been washed and powdered, and melted first with lime stone, and afterwards burnt with charcoal alone. See Lech.

ROSTEN, in the materia medica of earlier ages, a name given to crab eyes.

ROSTRUM (*Cycl.*)—The *rostrum* or snout in fishes varies very much in figure, and serves as a considerable article of distinction. It is 1. in some plagioplateous or depressed, as in the pike, *&c.* 2. In some it is conic in shape as in the oxyrynchus, *&c.* 3. In some it is extended into a long and sharp point, as in the common ones; and 4. In others it is triangular, or nearly so, as in the rays.

Rostrum is also used to signify an instrument wherewith paper is ruled for musical compositions.

ROT, in sheep (*Cycl.*)—This is the greatest of all the inconveniencies that attend the keeping these useful animals.

It is a very hard thing to prevent the *rot* if the year prove very wet, especially in May or June. Salt marshes and lands, where broom grows, are the best places of preservation for them. Sheep are sometimes all cleared of the *rot* when not too far gone with it, only by removing them into broom fields. Scurvy-grass, mustard, parsley, and thyme, are also good for the prevention of it.

Some propose the giving sheep half a handful of bay salt every month or oftener; and there is great probability that this may be of service; but the rational way of attacking all disorders in cattle, is by considering what are the causes of them. It will appear, upon enquiry, that wet seasons are the general occasions of the *rot* in sheep, and therefore it would be adviseable for the owners, when such seasons come on, to remove the animals into the driest pastures they can, and then to feed them principally with dry sweet hay, oats, bran, and the like, this would prevent the occasion; and if they were already a little infected, some salt given with their dry food, would be a happy means of curing them. *Mortimer's* Husbandry, p. 244.

ROTATED, *rotatus*, in botany, the name of a sort of flowers, so called from their shape, somewhat resembling a wheel. These are of the monopetalous kind, and are only a sub-distinction of the infundibuliform flowers. *Tourn.* Inst. p 116. Tab. 1. of Botany, Class 1. See the article Infundibuliformis.

ROTA-

ROTATION (*Cycl.*)—Mr. Winflow has given an account of this, as well as of pronation, and other circulatory animal motions. See Mem. de l'Acad. des Sciences, 1729.

ROTCHET, an Englifh name for the fifh, called by authors *cuculus*, and more frequently by us the *red gurnard*. *Willughby*'s Hift. Pifc. p. 282. See the article CUCULUS.

ROTELE, in zoology, a name by which fome call the *rutilus latior*, or *rubellio fluviatilis*, more frequently known by the name of the *rud* or *finfcale*, a river fifh with red bellyfins and tail. *Ray*'s Ichthyogr. p. 252. See RUBELLIO.

ROTHALS, in zoology, a name given by Gefner, and fome others to the *pochard*, or *red headed wigeon*; a bird diftinguifhed from all others of the duck kind, by having no variegation in its wings. See POCHARD.

ROTKNUSSEL, in zoology, a name by which the Germans call the *gallinula melampus* of Gefner. It is a bird fomewhat approaching to the fnipe kind; its back is brown, with a flight admixture of reddifh, and fome fpots of a dufky colour; its wings are variegated with black and white, and its beak and legs are black. It is common in many parts of Germany.

ROTOLO, an Egyptian weight of twelve ounces, each ounce confifting of twelve drachms, and each drachm of fixteen carrats. *Pocock*'s Egypt. p. 175.

ROTSCHWENTZEL, in zoology, the name of a bird, defcribed by Gefner and fome other authors, and feeming to be the fame with our *ruticilla*, or *red-ftart*. See the article RUTICILLA.

ROTSIMPA, in ichthyology, a name given by the Swedes to a fpecies of *cottus*, called by Jonfton and Schonveldt *fcorpius marinus*. It is different from the *fcorpæna* of the generality of writers, and is of the *cottus* kind. It is diftinguifhed by Artedi by the name of the fmooth *cottus*, with many thorns upon the head, and with the upper jaw fomewhat longer than the under one. See the article COTTUS.

ROTULA (*Cycl.*)—ROTULA, in natural hiftory, the name of a genus of the *echini marini*, of the general clafs of the placentæ. The characters of the *rotulæ* are, that they are flat fhells in form of a cake, compofed of various flat pieces, and formed into a round, fomething like that of a wheel; but wanting one or more parts of its outer ring, and radiated or dentated. Their mouth is fituated in the middle of the bafe, and the aperture of the anus in the third region of the axis, and marked with a cinquefoil flower at the fummit. The great and obvious character is however the dentated edge. Of this genus there are two known fpecies. 1. A kind with three very deep finufes, and four pervious foramina at the top, or fometimes only with two, and with a finely crenated pentagonal vertex; and 2. The folar echinus, which has ufually nine rays free from the outer ring. The vertex, in this fpecies, is round and denticulated, and variegated with very elegant lines. See Tab. of Teftaceous Animals, Nº 10. *Klein*'s Echin. p. 32.

ROTULA, in ichthyology, is alfo a name given by fome to the *faber* or *doree*. See the article FABER.

ROTUNDUS *major*, (*Cycl.*) in anatomy, a name given by Riolan, and fome others, to a mufcle, called by Vefalius and others the *tertius humeri*, and *tertius brachium moventium*. Albinus, Cowper, and others, call it *teres major*.

ROUGET, in ichthyology, a name given by the French to the fifh called the *lyra* and *capo* by authors. It is a fpecies of the *trigla*, and is diftinguifhed by Artedi by the name of the *trigla* with the long bifid fnout and tubulous noftrils.

ROUGH (*Cycl.*)—ROUGH-*fea*, in the fea language. See the article OVER-GROWN-*fea*.

ROUND (*Cycl.*)—ROUND *in*, or ROUND-*aft*, at fea, a term belonging to the main and fore fail. When the wind largeth, they fay, *Let rife the main tacks*, or *the fore-tacks! Hale aft the fore-fheet to the cat head*; *and the main fheet to the cubbridge-head!* And when thefe fheets are thus haled down they keep them from flying up with the *paffarado rope*. This work is called *rounding in* or *rounding aft* the fail.

ROUND-*feam*, in the fea language. See SEAM.

ROUND-*fplice*, in the fea language. See SPLICE.

ROUND-*top*, in the fea language. See TOP.

ROUSSIN, in the manege, is a ftrong well knit, well ftowed horfe, fuch as are commonly brought into France from Germany and Holland.

ROWELS *of a fpur*, in the manege. See SPUR, *Cycl.*

ROWLE, in a fhip, is a round piece of wood or iron, wherein the whip goes, being made to turn about, that it may carry over the whip the eafier from fide to fide.

ROYENA, in botany, the name of a genus of plants, the characters of which are thefe. The perianthium confifts of one leaf, which is inflated and permanent, and is lightly divided into five obtufe fegments at the edge. The flower is monopetalous, and confifts of a tube of the length of the cup, and an expanded mouth, which is divided into five oval and reflex fegments. The ftamina are ten very fhort filaments growing to the flower. The antheræ are oblong, acute, and double, and they ftand erect, and are of the length of the tube of the flower. The germen of the piftil is of an oval figure and hairy, and is divided into two ftyles, which are a little longer than the ftamina. The ftigmata are fimple; the fruit is an oval capfule, compofed of four valves, and furrowed with four deep lines, and contains only one cell, in which are four oblong and triangular nuts covered with a calyptra. This has been defcribed in Paradifus Batavus, and fome other books, under the name of a fpecies of the bladder nut, *ftaphylodendri fpecies*. *Linnæi* Gen. Pl. p. 193. *Hort. Amftel.* Vol. 1. p. 187. *Herm.* P. B. p. 232.

RUBECULA, in zoology, the name of a bird, commonly known in England, under the name of the *red breaft*, and called by fome *erithacus*. This is a folitary bird, and naturally fhy, but in winter will even come into peoples houfes in fearch of food. It is very careful in building its neft. It builds in the thickeft bufhes and hedges, where there are multitudes of fallen oak leaves, or the like large light matter. It covers its neft very artfully with large quantities of thefe leaves, and makes only one way to get into it, which is by a narrow paffage, and which it always covers with leaves when it goes abroad for food. *Ray*'s Ornitholog. p. 160.

RUBELLIO, in ichthyology, a name given by fome authors to a fmall fea fifh of a red colour caught in the Mediterranean, and more ufually called by writers on thefe fubjects the *erythrynus*. *Aldrovand.* de Pifc. p. 154. See the article ERYTHRYNUS.

RUBELLIO *fluviatilis*, the name of a frefh water fifh of the leather mouthed kind, called in Englifh a *rudd* or *roud*, and in fome places a *finfcale*. It is a common fifh in many of the rivers of England and Germany, and efteemed a well tafted fifh. They are in feafon all the year, except in the month of April, which is their fpawning time, and the males at that time are fubject to a great number of white fpots upon their heads, and are more rough than at any other feafon. It is a fifh broader than the carp, but thicker than the bream. It is of a brownifh yellow colour, and has very large fcales; the tail and belly fins are red, and the gills are commonly marked with a red fpot. *Willughby*'s Hift. Pifc. p. 252.

RUBELLUS, in zoology, a name given by fome authors to the common roach, and by others to the rudd or finfcale. *Gefner*, de Aquat. p. 965. See the articles RUTILUS and RUBELLIO.

RUBEOLA, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, fafhioned like a funnel, and either lightly dentated, or divided into four fegments at the edge. Thefe have fometimes a fingle, fometimes a double cup, and that of the two which was the lower, or the fingle one, if there were no other, is finally converted into a fruit compofed of two feeds.

The fpecies of *rubeola* enumerated by Mr. Tournefort are thefe. 1. The broad leaved *rubeola*. 2. The narrow leaved *rubeola*. 3. The procumbent *rubeola* with a very long fpike. 4. The common fmooth purple flowered fmall *rubeola*, called by many *rubia fquinanchica* and fquinancy wort. 5. The white flowered fmooth four leaved *rubeola* or fquinancy wort. 6. The rough Portugal *rubeola* with purple flowers. 7. The fea *rubeola*. *Tourn.* Inft. p. 130.

Thefe plants are called by Mr. Tournefort *rubeola* as a diminutive of *rubia*, or madder; moft other authors have called them *rubia fpicata*, or fpiked madder. They differ principally from the galliums in the funnel fhape of the flower.

RUBETA, the *toad*, in zoology, a creature fufficiently known. It is larger than the frog, its body is thick, its back broad, and its belly fwelled, and looking as if inflated, whence it is too heavy and unweildy to hop about as the frog does; its fkin is confiderably thick, and full of tubercles, of a dufky and blackifh colour on the back, and fpotted on the belly; and is naturally a loathfome and difagreeable object.

It feeds on the fame things that the frog does, worms, fnails, flies, and other infects; it feems alfo, that they are able to live on much lighter food, fince there have been many inftances of toads being found in the folid bodies of trees in holes, juft big enough for them to turn about in; and where there could be no nourifhment conveyed to them, except what they found in the juices of the tree. There are not wanting alfo inftances of their having been found in the fame manner in blocks of folid ftone, if we can credit the generality of authors. *Ray*'s Syn. Quad. p. 252.

RUBETRA, in zoology, a name by which Gefner and fome others have called that fpecies of the *œnanthe*, commonly known by the name of the *ftone-chatter*, *ftone-fmick*, or *moortitling*. *Gefner* de Avib. See the article STONE-CHATTER.

RUBIA (*Cycl.*)—RUBIA, *madder*, in the Linnæan fyftem of botany, a diftinct genus of plants, the characters of which are, that the calyx is an extremely fmall perianthium, fituated on the germen, and divided by four notches at its extremity. The flower is compofed of one fingle petal which is flat, divided into four fegments, hollow at the bafe, but forming no tube. The ftamina are four pointed filaments fhorter than the flower. The antheræ are fimple. The germen of the piftil is double, and fituated below the receptacle. The ftyle is flender, and bifid at top, the ftig-

mata are headed. The fruit is compofed of two round bodies, fmooth, and firmly joined together. The feeds are fingle, roundifh, and umbilicated. *Linnæi* Gen. Plant. p. 24.

The characters of this genus, according to Mr. Tournefort, are thefe. The flower confifts of one leaf, fhaped like a bell, and very open at the mouth, and divided into feveral fegments, and ufually perforated. The cup changes into a fruit compofed of two fucculent berries, which contain ufually an umbilicated feed. The leaves are all fet in rundles about the ftalk, feveral being placed at a joint in form of a radiated ftar.

The fpecies of *rubia* enumerated by Mr. Tournefort are thefe. 1. The common cultivated *madder*. 2. The great wild *madder* of Montpelier; and 3. The exotic four leaved fhining *madder*. The difpofition of the leaves, about the ftalks of thefe plants, ferve to diftinguifh them from other claffes, when they are not in flower; and this genus is abundantly diftinguifhed from all the others which have their leaves difpofed in this manner, by its having a berry, or juicy fruit, inftead of the dry fruits of the others. *Tourn.* Inft. p. 15. See MADDER, *Cycl.* and *Suppl.*
